CHANDLER, SAMUEL (1693–1766), English Nonconformist divine, was born in 1693 at Hungerford, Berkshire. He took a leading part in the deist controversies of the time, and discussed with some of the bishops the possibility of an act of comprehension. From 1716–26 he preached at Peckham, and for 40 years he was pastor of a meeting-house in Old Jewry. He died on May 8, 1766, leaving four vols. of sermons (1768), and a paraphrase of the Epistles to the Galatians and Ephesians (1777), several works on the evidence of Christianity, and various pamphlets against Roman Catholicism.

CHANDLER, ZACHARIAH (1813–1879), American politician, was born at Bedford, N.H., on Dec. 10, 1813. In 1833 he removed to Detroit, Mich., where he became a prosperous dry-goods merchant. He took a prominent part as a Whig in politics, and, impelled by his strong anti-slavery views, actively furthered the work of the "underground railroad," of which Detroit was one of the principal "transfer" points. He was one of the organizers in Michigan of the Republican Party, and in 1857 succeeded Lewis Cass in the U.S. Senate, serving until 1875. Throughout the Civil War he allied himself with the most radical of the Republican faction in opposition to President Lincoln's policy, and subsequently became one of the bitterest opponents of President Johnson's plan of reconstruction. From Oct. 1875, to March 1877, he was secretary of the interior in the cabinet of President Grant. In Feb. 1879, he was re-elected to the Senate.

He died at Chicago, Ill., on Nov. 1, 1879. By his extraordinary force of character he exercised a wide personal influence during his lifetime, but failed to stamp his personality upon any measure or policy of lasting importance.

CHANDOS, BARONS AND DUKES OF. The English title of Chandos began as a barony in 1554, and was continued in the family of Brydges (becoming a dukedom in 1719) till 1789. In 1822 the dukedom was revived in connection with that of Buckingham.

JOHN BRYDGES, 1st Baron Chandos (*c.* 1490–1557), a son of Sir Giles Brydges, or Bruges (d. 1511), was a prominent figure at the English court during the reigns of Henry VIII., Edward VI. and Mary. He took part in suppressing the rebellion of Sir Thomas Wyat in 1554, and as lieutenant of the Tower of London during the earlier part of Mary's reign, had the custody, not only of Lady Jane Grey and of Wyat, but for a short time of the princess Elizabeth. He was created Baron Chandos of Sudeley in 1554, one of his ancestors, Alice, being a grand-daughter of Sir Thomas Chandos (d. 1375), and he died in March 1557. The three succeeding barons, direct descendants of the 1st baron, were all members of parliament and persons of some importance. Grey, 5th Baron Chandos (*c.* 1580–1621), lord-lieutenant of Gloucestershire, was called the "king of the Cotswolds," owing to his generosity and his magnificent style of living at his residence, Sudeley Castle. His elder son George, 6th Baron Chandos (1620–1655), was a supporter of Charles I. during his struggle with Parliament. After the death of his brother William in 1676 the barony came to a kinsman, Sir James Brydges, Bart. (1642–1714), who was English ambassador to Constantinople from 1680–1685.

JAMES BRYDGES, 1st duke of Chandos (1673–1744), son and heir of the last-named, had been member of parliament for Hereford from 1698 to 1714, and, three days after his father's death, was created Viscount Wilton and earl of Carnarvon. For eight years, from 1705 to 1713, during the War of the Spanish Succession, he was paymaster-general of the forces abroad, and in this capacity he amassed great wealth. In 1719 he was created marquess of Carnarvon and duke of Chandos. The duke is chiefly remembered on account of his connection with Handel and with Pope. He built a magnificent house at Canons near Edgware in Middlesex. For over two years Handel, employed by Chandos, lived at Canons, where he composed his oratorio *Esther*. Pope, who in his *Moral Essays (Epistle to the Earl of Burlington)* doubtless described Canons under the guise of "Timon's Villa," referred to the duke in the line, "Thus gracious Chandos is belov'd at sight"; but Swift, less complimentary, called him "a great complier with every court." After his death on Aug. 9, 1744, Canons was pulled down. He was succeeded by his son Henry, 2nd duke (1708–1771), and grandson James, 3rd duke (1731–1789). The third duke's only daughter, Anna Elizabeth, who became Baroness Kinloss on her father's death, was married in 1706 to Richard Grenville, afterwards marquess of Buckingham; and in 1822 this nobleman was created duke of Buckingham and Chandos (*see* BUCKINGHAM, EARLS, MARQUESSES AND DUKES OF).

See G. E. C(okayne), *Complete Peerage* (1887–98); and J. R. Robinson, *The Princely Chandos, i.e.*, the 1st duke (1893).

CHANDOS, SIR JOHN (d. 1370), English soldier, fought at the siege of Cambrai (1337), at Crécy in 1346, and at Poitiers, where he saved the life of the Black Prince. For these services Edward III. gave him the lands of the viscount of Saint Sauveur in Cotentin, and appointed him lieutenant in France, and vice-chamberlain of the royal household in 1360. In 1362 he was made constable of Guienne, and defeated Charles de Blois at Auray in 1364. Chandos accompanied the Black Prince on his expedition in 1367, to restore Pedro the Cruel to the throne of Castile, and won the victory of Navaret over Bertrand du Guesclin. Appointed seneschal of Poitou in 1369, he was mortally wounded in an encounter with the French at the bridge of Lussac near Poitiers, and died on the day after the battle, Jan. 1, 1370.

CHANDRAGUPTA MAURYA (reigned 321–296 B.C.), known to the Greeks as Sandracottus, founder of the Maurya empire and first paramount ruler of India, was the son of a king of Magadha by a woman of humble origin, whose caste he took and whose name, Mura, is said to have been the origin of that of Maurya assumed by his dynasty. As a youth he was driven into exile by his kinsman, the reigning king of Magadha. In the course of his wanderings he met Alexander the Great, and, according to Plutarch (*Alexander*, cap. 62), encouraged him to invade the Ganges kingdom. On the death of Alexander he attacked the Macedonian garrisons and conquered the Punjab. He next attacked Magadha, dethroned and slew the king, and established himself on the throne (321). The great army acquired from his predecessor he increased until it reached the total of 30,000 cavalry, 9,000 elephants and 600,000 infantry; and with this huge force he overran all northern India, establishing his empire from the Arabian sea to the Bay of Bengal.

Seleucus I Nicator crossed the Indus in 305, but was defeated by Chandragupta and forced eventually to a humiliating peace, by which the empire of the latter was still further extended in the north.

About six years later Chandragupta died, leaving his empire to his son Bindusura.

An excellent account of the court and administrative system of Chandragupta has been preserved in the fragments of Megasthenes, who came to Pataliputra as the envoy of Seleucus.

See J. W. MacCrindle, *Ancient India as Described by Megasthenes and Arrian* (Calcutta, 1877); V. A. Smith, *Early History of India*, ed. S. M. Edwardes (Oxford, 1924); also the article INDIA: *History*.

CHANGARNIER, NICOLAS ANNE THÉODULE (1793–1877), French general, was born at Autun on April 26, 1793. Educated at St. Cyr, he served for a short time in the bodyguard of Louis XVIII., and entered the line as a lieutenant in January 1815. In 1830 he entered the Royal Guard and was sent to Algeria, where he served with great distinction until 1848, and had just succeeded Gen. Cavaignac as governor of the colony when he was recalled to command the National Guard. An avowed enemy of republican institutions, he at first upheld the power of the president; but in January 1851 he opposed Louis Napoleon's policy, was deprived of his double command, and at the *coup d'état* in December was arrested and sent to Mazas until his banishment from France by the decree of Jan. 9, 1852. He returned to France after the general amnesty. In 1870 he was present with the headquarters, and afterwards with Bazaine in Metz. He was employed on an unsuccessful mission to Prince Frederick Charles, commanding the German army which besieged Metz, and on the capitulation became a prisoner of war. At the armistice he returned to Paris, and in 1871 was elected to the National Assembly by four departments, and sat for the Somme. He took an active part in politics, defended the conduct of Marshal Bazaine, and served on the committee which elaborated the monarchical constitution. When the comte de Chambord refused the compromise, he moved the resolution to extend the executive power for ten years to Marshal MacMahon. He was elected a life senator in 1875. He died in Paris on Feb. 14, 1877.

See Comte d'Antioche, *Changarnier* (1891).

CHANG CHUN, KIU (1148–1227), Chinese Taoist sage and traveller, was born in 1148. In 1219 he was invited by Jenghiz Khan, founder of the Mongol empire and greatest of Asiatic conquerors, to visit him. Jenghiz' letter of invitation, dated May 15, 1219 (by present reckoning), has been preserved, and is among the curiosities of history; here the terrible warrior appears as a meek disciple of wisdom, modest and simple, almost Socratic in his self-examination, alive to many of the deepest truths of life and government. Chang Chun obeyed this summons; and leaving his home in Shantung (Feb. 1220), journeyed first to Peking. Learning that Jenghiz had gone far west upon fresh conquests, the sage stayed the winter in Peking. In February 1221 he started again and crossed eastern Mongolia to the camp of Jenghiz' brother Ujughen, near Lake Bör or Buyur in the upper basin of the Kerulun-Amur. Thence he travelled south-westward up the Kerulun, crossed the Karakorum region in north-central Mongolia, and so came to the Chinese Altai, probably passing near the present Uliassutai. After traversing the Altai he visited Bishbalig (modern Urumtsi), and moved along the north side of the Tian Shan range to lake Sairam, Almalig (or Kulja), and t[he]

rich valley of the Ili. We then trace him to the Chu, over this river to Talas and the Tashkent region, and over the Jaxartes (or Syr Daria) to Samarkand, where he halted for some months. Finally, through the "Iron Gates" of Termit, over the Oxus, and by way of Balkh and northern Afghanistan, Chang Chun reached Jenghiz' camp near the Hindu Kush. Returning home he followed much the same course as on his outward route: certain deviations, however occur, such as a visit to Kuku Khoto. He was back in Peking by the end of January 1224. From the narrative of his expedition (the *Si yu ki,* written by his pupil and companion Li Chi Ch'ang) we derive some of the most faithful and vivid pictures ever drawn of nature and man between the Great Wall of China and Kabul, between the Aral and the Yellow sea. We may particularly notice the sketches of the Mongols, and of the people of Samarkand and its neighbourhood; the account of the fertility and products of the latter region, as of the Ili valley, at or near Almalig-Kulja; and the description of various great mountain ranges, peaks and defiles, such as the Chinese Altai, the Tian Shan, Mt. Bogdo-ola (?) and the Iron Gates of Termit. There is, moreover, a noteworthy reference to a land apparently identical with the uppermost valley of the Yenisei. After his return Chang Chun lived at Peking till his death on July 23, 1227. By order of Jenghiz some of the former imperial garden grounds were made over to him for the foundation of a Taoist monastery.

BIBLIOGRAPHY.—*See* E. Bretschneider, *Mediaeval Researches from Eastern Asiatic Sources,* vol. i, pp. 35–108, where a complete translation of *Si yu Ki: Travels to the West of K'iu Ch'ang Ch'un* is given, with a valuable commentary; C. R. Beazley, *Dawn of Modern Geography,* iii, 539. (C. R. B.)

CHANGE, the substitution of one thing for another, hence any alteration or variation, so applied to the moon's passing from one phase to another. The use of the word for a place of commercial business has usually been taken to be a shortened form of "exchange" (*see* EXCHANGE, FOREIGN). "Change" is particularly used of coins of lower denomination given in substitution for those of larger denomination or for a note, cheque, etc., and also for the balance of a sum paid larger than that which is due. A further application is that in bell ringing, of the variations in order in which a peal of bells may be rung (*see* BELL).

CHANGELING, the term used of a child substituted or changed for another. It was formerly believed that infants were sometimes stolen from their cradles by the fairies before christening, so that in the highlands of Scotland babies were strictly watched till then. Any specially peevish or weakly baby was regarded as a changeling. The belief is referred to by William Shakespeare, Edmund Spenser and other authors.

See Pennant, *Tour in Scotland,* p. 257 (1796); W. Wirt Sikes, *British Goblins* (1880).

CHANGE OF LIFE. The period of life occurring naturally in women when the reproduction function ceases. It occurs artificially in women when the ovaries are removed.

Analogous changes occur in men at a later period in life also associated with alterations in reproductive capacity. (*See* MENOPAUSE; CLIMACTERIC.)

CHANGOAN, a tribe or small group of tribes of South American Indians, forming an independent linguistic stock. The Changos occupied the arid coast of the desert of Atacama in northern Chile. They are an almost dwarfish fisherfolk of very simple culture, and are now nearly extinct, except in the vicinity of Cobija. The Changos depended largely on shellfish for food. They wore little clothing, and had huts of poles and thatch. Their dead were buried at length instead of flexed.

See E. Boman, *Antiquités de la Région Andéenne de la République Argentine et du Désert d'Atacama* (Paris, 1908).

CHANGRA or CANKIRI (anc. *Gangra;* called also till the time of Caracalla, *Germanicopolis,* after the emperor Claudius), the chief town of a vilayet of the same name in Turkey, situated in a rich, well-watered valley; altitude 2,500 ft. The ground is impregnated with salt and the town is unhealthful. Pop. (1950) 14,161. Gangra, the capital of the Paphlagonian kingdom of Deiotarus Philadelphus, son of Castor, was taken into the Roman province of Galatia on his death in 6–5 B.C. The earlier town was built on the hill behind the modern city, on which are the ruins of a late fortress; while the Roman city occupied the site of the modern. In Christian times Gangra was the metropolitan see of Paphlagonia.

Synod of Gangra.—Conjectures as to the date of this synod vary from 341 to 376. The synodal letter states that 21 bishops assembled to take action concerning Eustathius (of Sebaste?) and his followers, who contemned marriage, disparaged the offices of the church, held conventicles of their own, wore a peculiar dress, denounced riches, and affected especial sanctity. The synod condemned the Eustathian practices. The 20 canons of Gangra were declared oecumenical by the Council of Chalcedon, 451.

See Mansi ii, pp. 1095–1122; Hardouin i, pp. 530–540; Hefele, 2nd ed., i, pp. 777 *sqq.* (Eng. trans., ii, pp. 325 *sqq.*).

CHANG TSO-LIN (1873–1928), Chinese military leader, born in the province of Fengtien. Of humble origin and without education, he was successively a swineherd, a menial in the Catholic mission at Newchwang and a labourer on the Peking-Mukden railway. Later he abandoned regular employment and rose to prominence in 1904 as a leader of *Hunghutse,* or Manchurian brigands, when he and his band became irregular allies of Japan during the Russo-Japanese War. After the Treaty of Portsmouth, under Japanese advice, he submitted to the Chinese government, and he and his following were incorporated in the Chinese army. He received quick promotion, and attained command of a division. In 1913 he was appointed *Tutuh,* later *Tuchun* (both terms denoting military governor) of Fengtien.

Chang Tso-lin faithfully served the young republic of China, and opposed both Yuan Shih-k'ai's monarchical aspirations in 1916 and Chang Hsün's attempted restoration of the imperial dynasty in 1917. In 1918 he was appointed inspector-general of the three eastern provinces, *i.e.,* of Manchuria, and, while civil government slowly weakened, his military control became absolute. He adopted the course, unusual in China, of punctually paying, feeding and disciplining his troops, and by this means he became a dominant factor in the unstable politics of the country. In civil life his activities were boundless: mining, farming, stock breeding, banking, railway construction, in these and many other forms of industrial enterprise, his hand was felt.

During the concluding 12 years of his life, while maintaining autocratic control of Manchuria, he made four descents upon Peking, actuated on each occasion by the desire to set up a stable form of government for the country. In 1920, when, during the halting and incapable presidency of Hsu Shi-chang, the government fell under the control of the reactionary militarists known as the Anfu party, he drove their leaders into retirement, and, in co-operation with Ts'ao Kun, the *Tuchun* of Chihli, made an attempt to form an administration. Their efforts were fruitless, and in 1921 he again came to Peking and installed a cabinet under Liang Shih-yi. Upon this occasion he was defeated by General Wu Pei-fu and driven back to Manchuria, whereupon he declared the independence of the three eastern provinces. His third incursion took place in 1924, when large forces under Wu Pei-fu assembled near the Great Wall to repel the Manchurian invasion. Owing to the treacherous defection of Fêng Yu-hsiang, who withdrew to Peking and "declared for peace," Wu Pei-fu's forces collapsed, and Chang's army pressed forward, eventually occupying Shantung, Anhwei and Kiang-su. In the latter part of this year he was occupied in suppressing the revolt of one of his lieutenants, by name Kuo Sung-ling, whom he defeated outside Mukden and executed. His final coming to Peking was in Dec. 1926, when he once more announced his intention to reorganize the government. In June 1927, he formed a cabinet consisting entirely of his own adherents, with Pan Fu as premier, he himself, under the title of generalissimo, becoming president. He watched from Peking the victorious Southern Nationalist army reach the Yangtze, and their further advance in 1928 to Peking. His troops, after some show of defending the capital, received orders to stop further opposition, and Chang himself left for Mukden by train on June 3. Before he reached his destination the train was bombed and he succumbed to injuries received.

Soft-voiced and of delicate constitution, suave yet resolute, Chang Tso-lin would have been an admirable viceroy under the

Empress Dowager's régime. It was the only system of government he understood, and his failure to bring about union and a stable government is evidence of how far removed he was *au fond* from realizing the strides which the country had made in acquiring race-consciousness and a political sense. His administrative achievements in Manchuria, and his friendliness towards foreigners, are among his claims to be styled a Chinese patriot.

(W. E. L.)

CHANNEL FERRY, the first type of cross-channel ferry between England and France was designed to meet the urgent need to supply the British armies in France and Belgium during World War I. An inland water transport section of the royal engineers was formed in 1914 to make use of the waterways behind the lines and a similar organization (later known as the Directorate of Inland Waterways and Docks, R.E.) was set up in England. A cross-channel barge route was started from Richborough, in Kent, to Calais, where the barges continued up the canals to Vendroux, Audruicq, Zeneghem and other points. The 255 steel barges so employed, each carrying about 200 tons of stores, ammunition, etc., were towed across the chanel by tugs, of which 67 were available, and provided a reliable service; no barge was ever reported lost on the channel crossing.

However, this method did not suffice for all needs and was, from 1917 to 1918, supplemented by three specially built train ferries which sailed from Richborough to Calais and Dunkirk, and from Southampton to Dieppe. Railway vehicles were propelled into the ferry at the stern, the two entry tracks spreading into four tracks on the deck of the vessel itself; the capacity in terms of four-wheeled freight cars was 54 per ferry. Rail-mounted guns and locomotives could be carried on the two centre tracks. About 1,000 locomotives were thus dispatched from Richborough to Audruicq shops, almost ready for instant service.

Nearly all these locomotives were returned to England in 1919 by these same train ferries, together with passenger coaches which had been employed on ambulance trains or leave and demobilization trains in France, Belgium, Germany and Italy. In 1919 the train ferries were adjusted to take motor vehicles instead of freight cars, if required.

At the ports, vehicles were loaded or unloaded by means of movable aprons, which could be raised or lowered to overcome small tidal differences in level. Because of the range of channel tides, amounting to 25 ft., the aprons at Calais and Dunkirk had to be within enclosed water areas, the levels being protected by locks.

After World War I the ferry services were discontinued but, after a few special voyages carrying British-built rolling stock for export to the continent, they were acquired by Great Eastern Train Ferries, Ltd., and placed in service between Harwich and Zeebrugge, where suitable aprons (in effect, hinged lifting bridges) were constructed for loading and unloading purposes. The tidal range at Harwich is only 12½ ft. and, therefore, the necessity of passing through locks was obviated at that port. This service was inaugurated in April 1924 and required the close co-operation of the London and North Eastern railway. The service acquired traffic in vegetables, cheese, eggs, fruit, machinery, silk and rolling stock.

In conjunction with Great Eastern Train Ferries was the Anglo-Belge Ferry Boat company, which owned many of the freight cars employed on the train ferry service. Later the three former wartime train ferries, operating between Harwich and Zeebrugge, became part of the London and North Eastern railway fleet.

Further train ferry developments across the channel were delayed by the possible building of a channel tunnel, but that project was turned down by the British government in 1930.

The Harwich-Zeebrugge freight service permitted traffic to move without transhipment between all parts of England, Scotland and Wales and any station served by the standard gauge railways of continental Europe, stretching from Narvik to Sicily and from the Spanish frontier to Istanbul. Its success led the Southern railway to start in Oct. 1936, in conjunction with the then Nord railway of France, a train ferry service from Dover to Dunkirk. Three vessels, with a gross tonnage of 2,989 each, were specially built in Great Britain, the "Twickenham Ferry," the "Hampton Ferry," and the "Shepperton Ferry"; they were designed to carry passenger coaches and sleeping cars as well as freight cars across the English channel.

Difficulties were experienced in the construction of the train ferry dock at Dover, because of faults in the chalk formation, but on completion a night ferry service for passengers was started between London (Victoria) and Paris (Nord), as well as other services for freight traffic.

As a consequence of World War II, the London and North Eastern railway train ferry fleet was reduced, but the two fleets, Harwich-Zeebrugge and Dover-Dunkirk, received new vessels in replacement. Though subject to restrictions on international trade, traffic tended to increase after World War II and the night ferry passenger service between London and Paris proved exceedingly popular. The Harwich route continued to cater for freight traffic only.

Train ferry services occur other than across the English channel and the North sea. One of the most famous examples is the train ferry service across the Great Belt, operated by the Danish State railways. This carries diesel trains, sleeping cars and passenger coaches on the Stockholm-Paris and other services, while jointly with the Swedish State railways a route is operated between Malmö and Copenhagen. Before World War II there was a joint German-Swedish service between Sassnitz and Trelleborg, while a Danish service ran between Gjedser and Warnemunde, but these routes were diverted after 1946. Another European instance is the train ferry operated by the Italian State railways from the toe of Italy to Sicily, on which fine motor vessels were placed in service after 1946.

Japanese National railways have long operated some train ferry routes between the several islands. The Canadian National railways operate a train ferry service to Prince Edward Island. Others occur on Lake Michigan, where freight cars are carried by train ferries of the Grand Trunk Western (Canadian National railways) and of the Pere Marquette (Chesapeake & Ohio railway) from ports in Michigan, such as Grand Haven and Ludington, to Milwaukee, Manitowoc and Kewaunee in Wisconsin.

Train ferries ply between Cuba and certain east coast and gulf ports in the United States and railway equipment is ferried across such great harbours as San Francisco and New York.

(C. E. R. S.)

CHANNEL ISLANDS (French *Iles Normandes*), an archipelago in the English channel, the only part of the ancient duchy of Normandy still attached to the English crown. It lies from 50 to 100 mi. south of Weymouth in the bay formed by the west coast of Normandy and the north coast of Brittany. There are four principal islands: Jersey, 44⅞ sq.mi., pop. (1951 census) 57,206; Guernsey, 24½ sq.mi., pop. 43,547; Alderney, 3 sq.mi., pop. 1,321; and Sark, 2 sq.mi., pop. 563. St. Helier is the chief town of Jersey, St. Peter Port of Guernsey and St. Anne of Alderney. Planes fly regularly from London, Southampton, Bristol and Cardiff to Guernsey and Jersey; ships sail daily from Weymouth or Southampton. Jersey is in regular communication by air and sea with Guernsey, Dinard and St. Malo; Guernsey by air and sea with Jersey and Alderney, by air with Dinard and by sea with Sark.

The four main islands, JERSEY, GUERNSEY, ALDERNEY and SARK are each described in separate articles.

Lesser Islands.—Besides the main islands there are innumerable islets in the group. To the north lie the Casquets, where in 1744 1,100 men perished when H.M.S. "Victory" was wrecked, and where many lives were lost in 1899 when the mail boat "Stella" went down. The lighthouse keepers are the only inhabitants.

Ortac and Burhou are uninhabited; a large colony of gannets has taken possession of the former.

Lihou (38 ac.), off the west coast of Guernsey, was the site of the once famous church of Notre Dame de Lihou, served by the monks of Mont St. Michel. This was so sacred a spot that, when Peter Heylyn wrote 100 years after the Reformation, passing fishermen still lowered their sails in salute, though only the steeple

remained. This steeple was blown up in 1793 lest it should give cover to invaders.

Between Guernsey and Sark, 3 mi. from the former, is Herm (320 ac.), with 36 inhabitants at the 1951 census. In 1155 Henry II gave the island to the abbey of St. Helier, which established a small daughter house (*cenobiolum*) there with a church dedicated to St. Tugual. In 1440 Franciscans built a friary. John Leland's map of 1540 has the note: "Once a cell of Canons Regular, now Franciscans." When the Reformation overtook the islands, Herm became for a time the last refuge of the Roman Catholics. Later the governors of Guernsey used it as a game preserve. Philip Dumaresq wrote in 1685: "The Governor keeps deer there, having a lodge for a keeper, where formerly stood a convent, the ruins whereof are yet seen." In the 19th century it was let to private tenants, one of whom, the German zoologist, Prince von Blücher, acclimatized wallabies there; World War I ended his tenancy.

In 1946 the States of Guernsey bought the island for use as a resort for Guernsey. By some freak of the tide a shell beach half a mile long has been formed, on which about 200 varieties of shells have been found.

South of Herm is Jethou (44 ac.), a round islet about half a mile in diameter. Richard, duke of Normandy, granted it to his shipmaster Restald, who became a monk of Mont St. Michel and bequeathed it to his abbey; but the only income the abbey ever derived from it came from wreckage. An assize roll of 1309 reported: "There hath rarely lived there any man." But in 1951 there were 13 inhabitants. Botanically Jethou is interesting as the home of a white pimpernel and a yellow forget-me-not said to be peculiar to the island.

West of Sark and separated only by a channel 70 yd. wide is Brecqhou (74 ac.). Before World War II it was a favourite picnicking place with only one farmhouse on it; then a mansion was built there with gardeners' cottages, etc., and the whole island became private property.

Northeast of Jersey lie the Ecrehou Islands and south of Jersey the Minquiers Islands, two long reefs of rocks. At low tide the Minquiers reef is larger than Jersey, but at high tide only one peak the Maîtresse Ile, is large enough for habitation. On the Ecrehou three islets, Marmoutier, Blanche Ile and Maître Ile, have houses on them. Sovereignty over the Ecrehou and Minquiers Islands was for more than 300 years a matter of dispute between France and England. In Dec. 1951, the question was referred to the International Court of Justice.

Further south Les Roches Douvres with their lighthouse and the 15 islets of Chausey with their one farm, lighthouse, church and two hotels, and their floating population of lobster trappers (the great granite quarries that were once the staple industry have gone bankrupt) form part of the Channel Islands geologically; but apart from one brief interval they have always been under French rule.

PHYSIOGRAPHY

The Channel Islands are summits of a partially submerged portion of the Armorican massif and fall topographically into four groups. The northerly group comprises Alderney, Burhou, Ortac, the Casquets and other islets which lie due west of Cap de la Hague. The westerly includes Guernsey, Herm, Jethou, Sark and several islets; the Little Russel strait separates Guernsey from Herm, the Great Russel strait separates Herm from Sark. A third group, separated from the second by La Déroute strait, includes Jersey and the Ecrehou Islands. A fourth consists of the Minquiers Islands and the Iles Chausey.

A fall in sea level to the 30-fathom line would connect all the islands with the Cotentin peninsula of Normandy. In postglacial times with a rising temperature the sea has gradually risen, successively cutting off islands and groups of islands. Jersey probably remained connected with the continent till the Bronze Age.

Geology.—Geologically the islands are related to the Cotentin peninsula and Brittany. Metamorphic rocks, almost certainly pre Cambrian, cover large areas. Much of Sark consists of hornblende, schist and associated gneiss. Granite and diorite gneisses form southern Guernsey, the Paternosters, Dirouilles, the Ecrehou Islands, the Chaussée des Boeufs and the Minquiers Islands. Mudstones and fine sandstones (greywackes), probably pre-Cambrian (Fr. *Briovérien*), form much of Jersey and a minute patch of southwest Guernsey. In east Jersey these rocks are overlaid by massive volcanic flows, probably pre-Cambrian (Uriconian), consisting of andesite followed by rhyolite, which shows exceptionally fine spherulite structures. East and southeast Alderney and the reefs north and northwest of the island consist of Lower Cambrian sandstone (the *grès pourpré* of Normandy). The northeast corner of Jersey consists of an unusually coarse and massive conglomerate, probably Permian. In north Guernsey and north and west Alderney gabbros and diorites are dominant. Similar rocks also occur in southeast Jersey and around Sorel point. In all cases granite intrusions have followed, giving rise by mixing to a variety of hybrid diorites.

Granites without associated diorites and gabbros form the north and southwest parts of Sark, the west of Brecqhou, all Herm and Jethou, extensive tracts of northwest and southwest Jersey and all the Chausey group. The plutonic rocks of Alderney are pre-Cambrian; most of those of Jersey and those of the Chausey Islands probably carboniferous, but except in Alderney there is no clear evidence of age. All the rocks so far described, especially the metamorphic and plutonic series, are cut by numerous intrusive dykes of dolerite and mica-lamprophyre and, in west Alderney and southeast Jersey, of granite-porphyry. Raised beaches occur at about 25 ft., 60 ft. and 120 ft. above the modern sea level. They are overlaid by head or stony clay and by brick earth or loess of Pleistocene age. More recent deposits of peat, alluvium and blown sand, with relics of Neolithic and later human occupation, form the low-lying coastal areas. Peat and forest beds found down to low-tide mark are evidence of a sea level lower than at present.

Flora.—The two main factors affecting the flora of the Channel Islands are the lack of chalk and limestone and the warm climate. About 700 species of wild flowers have been identified, mostly belonging to the Lusitanian element. Many flowers bloom in December and introduced plants such as *Erigeron mucronatus* from Mexico and the *Nerine sarniensis* from South Africa flourish.

In the 17th century bulbs of the latter, now called the Guernsey Lily, having at Cape Town been taken on board a ship returning home from Japan, were washed ashore at Guernsey when the ship was wrecked near the Channel Islands. Several Mediterranean species, such as *Echium plantagineum* and *Linaria pelisseriana* in Jersey and the grass *Milium scabrum* in Guernsey, are not found in the British Isles proper.

Jersey became an island at a much later date than Guernsey and so it has a larger and more varied flora (about 50 more species of flowering plants); for example the wood anemone and cross-leaved heath are found in Jersey but not in Guernsey. After the last Ice Age the land sank and when it rose again forest spread from southern Europe. Guernsey and its near-by islands were some of the high places in this forest that were cut off when the land sank once more. There are no woods left in any of the islands because of intense cultivation, but analysis of pollen from Jersey peat shows that oak, ash, birch, lime, wych-elm, beech, pine, cedar, hazel and alder are all indigenous species. Other trees spread to Jersey later. Ferns, mosses, fungi and lichens are abundant; a form of the European quillwort, *Isoetes hystrix*, is found in Guernsey and Alderney but nowhere else in the United Kingdom.

Fauna.—Some animals found in Jersey never reached the Guernsey group because, as explained above, the former became an island so much later. The fauna is continental rather than British in character. The Guernsey vole belongs to the older fauna; the bank vole is confined to Jersey and is its commonest mammal. Probably late arrivals, the mole is found only in Jersey and Alderney, and the squirrel only in Jersey. The stoat occurs in Guernsey and Jersey but there are no weasels. All the islands have hedgehogs, mice, rats, rabbits and continental types of shrews.

The Jersey shrew, a variety of the British shrewmouse, is found only in Jersey.

Among the commonest birds are jays and magpies. Woodland and small species are not well represented. Barn owls, peregrines, gannets, storm petrels and many more breed in the islands. Winter visitors include the short-eared owl, snow bunting and water rail as well as thousands of waders, swans, geese and ducks that feed on grass wrack along the shores. The oyster catcher, Kentish plover and mallard stay to breed. Many migrants pass through in spring and autumn. The corn crake, once common, is only a summer visitor.

Pheasants and partridges have been shot to extinction in Guernsey and Jersey.

Porpoises and dolphins are plentiful around the coasts while the ormer, not found in the British Isles proper, occurs on all the shores.

The common toad and palmated newt, the green lizard, wall lizard and slowworm, and the grass snake are indigenous to Jersey. There are no poisonous snakes. The frog, *Rana dalmatina*, not found in Great Britain, Ireland or northern France, occurs in Jersey, Guernsey, Alderney and Sark. Of insects, one of the ant lions, a group not represented elsewhere in the United Kingdom, inhabits the Channel Islands.

HISTORY

The early history of the islands is obscure. About 100,000 B.C. Neanderthal men were living in caves in Jersey, which was then joined to the continent. Iberian settlers about 2000 B.C. left flint implements everywhere, great chamber tombs (dolmens) in Jersey, Guernsey and Alderney, and two impressive statues of their goddess mother in Guernsey. Next came the Gauls; then the Romans added the islands to their empire. Coins show that for more than 500 years their money circulated, but only in Alderney has any trace of Roman buildings been found. Several of the early Breton saints are said to have visited the islands, the best-authenticated stories being those of St. Samson's mission to Guernsey (*c.* A.D. 530) and St. Magloire's foundation of a monastery in Sark (*c.* 568).

History proper begins when Rollo the Viking established the duchy of Normandy. In A.D. 933 William Longsword, the second duke, annexed the whole archipelago and for the next 270 years it was ruled from Rouen. William of Normandy's conquest of England made no difference to this. The islands' seat of government was not moved to Westminster but remained in Rouen.

But in 1204, when the king of France conquered continental Normandy, some new form of government had to be evolved. The islands were never incorporated with England. "The King of England hath nothing in these islands," said the assize roll of 1331, "except his status as Duke." So gradually a home rule constitution came into being.

A document ascribed to King John was long regarded by the islanders as their "magna carta," but modern criticism leaves little doubt that it is not genuine. But each island possessed judges, known as *jurats*, elected by the larger landowners (*optimates*)—12 each for Jersey and Guernsey, 6 each for Alderney and Sark. This is an institution peculiar to the islands, of which the origin is unknown. These *jurats* assumed control and issued ordinances, the breach of which they were able as judges to punish. The king in his capacity as duke appointed a warden to represent him; and later, when wardens were often absentees, two bailiffs were installed as their lieutenants, one for Jersey, the other for the rest of the group. The bailiffs, who at first were servants of the warden, in the 14th century became the king's bailiffs, representatives of the crown.

Lying as they did within sight of ships passing down the English channel, the islands were constantly raided. In the 9th century the Vikings began to plunder them and continued to do so for 100 years. Robert Wace, the Jersey poet, wrote of the devastation "En Auremen (Alderney), en Guernesi,/ En Sairc, en Erim (Herm), en Gersi." After their separation from Normandy the incursions were resumed. After a French raid in 1294 a Jersey petition reported that "Men and women were killed to the number of 1,500. The houses were burnt and the corn; so the people have nothing to eat." In 1336 David Bruce, when driven from his Scottish throne, "attacked Guernsey and Jersey inhumanly, committing arson, murder, and divers other atrocities." In 1339 another Jersey petition said: "The island hath been destroyed and burnt three times this year." This continued till 1484 when a bull of Pope Sixtus IV brought relief. Having learned with horror, he said, that miscreants were wont to land, burn houses and goods, carry off crops and cattle and murder the inhabitants, he pronounced "sentence of eternal damnation with confiscation of goods" on all who should commit such crimes in the islands "or within sight of them as far as human eye shall reach."

This secured the islands the unusual privilege of neutrality, which even survived the Reformation, for when Elizabeth I confirmed the prerogatives of Jersey she wrote: "One is that in time of war merchants of all nations can without impediment frequent the islands to escape storms or for purposes of trade, and depart without molestation, and remain in safety as long as the island is in sight."

The Reformation reached the islands from France and won a rapid victory. The church became fervently Calvinist with the Presbyterian form of government and Presbyterian ordination. Under Mary an unsuccessful attempt was made to restore Catholicism, but the martyrdom of three women in Guernsey, one of whom gave birth in the fire to a child, confirmed the people yet more firmly in their Protestant faith.

In 1620 James I forced Jersey to accept Anglicanism, but Presbyterianism survived in Guernsey till 1660 and in Sark till 1674. The islands before the Reformation formed part of the diocese of Coutances, but later they were placed under the bishops of Winchester.

During the Civil Wars their Puritan views led most of the islanders to support the parliament. In Guernsey the royalist lieutenant governor was besieged for nine years in Castle Cornet. In Jersey at first the same thing happened. Sir Phillippe de Carteret, the lieutenant governor, was besieged in Elizabeth castle and died there; but his nephew, Sir George Carteret, recovered the island for the king and held it with an iron hand till 1651, when he too had to surrender.

William of Orange abolished the neutrality of the islands in 1689, and during the war of 1778–83 there were two unsuccessful attacks on Jersey, in 1779 and 1781. The second, under Baron de Rullecourt, is famous for the victory over the invaders achieved through the bravery of the young Major Francis Peirson, who however fell when the French were on the point of surrender. During the revolutionary period in France the islands were the home of many refugees. In the 18th century various attempts were made to introduce the English customhouse system, but these proved practically a failure, and the islands throve on smuggling and privateering down to the Napoleonic wars.

The 19th century brought some prosperity from maritime commerce so long as wooden sailing ships were in general use. Later, intensive cultivation for export to English markets caused unprecedented development. The encouragement of the tourist traffic was a contributing factor.

During World War I the islands suffered little, but in World War II, when France surrendered, their defense became impossible and the government offered to evacuate the inhabitants. The response of the islands varied. In Alderney the entire population embarked. Of Guernsey's 43,000 inhabitants 23,000 departed. In Jersey 41,000 remained and only 10,000 left. The Germans occupied all the islands on June 30–July 1, 1940, and fortified them with attendant destruction and deportations, to be "the mailed fist of the Western Wall." Following the German surrender in Europe, the islands were relieved by British forces on May 9, 1945.

Language.—From the 9th to the 19th centuries everyone in the islands spoke French. Debates in the states (the insular legislature), pleadings in the courts and sermons in the churches were in French, while the countryfolk spoke, as some still do, a dialect of Old Norman French. But the steady inflow of English residents made English so dominant that French became almost a foreign

language. In Alderney, where English soldiers and harbour builders outnumbered the natives, French had succumbed by the middle of the 19th century. The other islands gradually followed suit. In 1900 Jersey allowed English to be spoken in the states. French ceased to be the official language in Guernsey in 1946.

GOVERNMENT AND ADMINISTRATION

Constitution.—After the upheaval of World War II the islands could not settle down to the *status quo ante*. A demand arose for reforms, and the privy council sent a commission to advise the local authorities. From these discussions a new constitution emerged for each island, but much of the old framework survived. The lieutenant governors still represent the queen and are the channels of communication between the local government and the crown. The bailiffs retain their duties as chief justices, prime ministers and speakers. The states lost none of their powers, though they were purged of nonelected members. In Jersey they consist of elected senators, *connétables*, and deputies; in Guernsey of *conseillers*, elected by an intermediate body called the States of Election, people's deputies, representatives of the *douzaines* (parish councils), and representatives of Alderney. In each island the *jurats* were relegated to their original duties as judges, and in Guernsey the *connétables* too lost their seats in the states. But Jersey retained its *centeniers* and *vingteniers;* Guernsey its sheriff with his sword and gold chain and its *douzeniers;* Sark its *sénéchal* and *prévot*.

In Alderney, however, the restoration of its old status as a semi-independent political unit proved impracticable, and for financial and administrative work it was amalgamated with Guernsey.

Law.—The laws of the islands differ in certain details. The law of inheritance for example is different in Jersey and Guernsey and Sark. Guernsey has no trial by jury, though it has long been the practice in criminal cases in Jersey. But in each island the legal system is based on the 13th-century *Grand Coutumier de Normandie*. One example of these old Norman customs is the *clameur de Haro*. If an islander finds someone interfering with his property, he has only to cry "Haro, haro, haro! A l'aide mon prince! On me fait tort" and the aggressor has to desist till the court has decided the case. The English law courts have no authority in the islands. Appeals from decisions of the local courts are made to the queen in council; however, during 1952 legal provisions were made for an insular court of appeal for the whole group.

Feudal Relics.—The Normans brought the feudal system with them and divided the islands into fiefs. Each *seigneur* had his seigneurial court and some their own gallows. Most of these powers have long disappeared but a few survive. In Jersey, if a landowner dies without a direct heir, the *seigneur* claims for a year and a day the income of his estate; the *seigneurs* of St. Ouen's and La Motte still license taverners. In Sark the dame receives a tithe of all crops grown and one-thirteenth of the price whenever land is sold. No one but she may keep pigeons or a female dog.

Defense.—The militia, which played so large a part in the past in the defense of all the islands, in which for more than 500 years every man from 16 to 60 had to serve, became unsuitable for modern warfare. After World War II the problem of the islands' military training came under discussion. In May 1952 Guernsey rejected conscription on the grounds that in any case enough volunteers came forward; in the same year Jersey tabled a measure to introduce two years' compulsory service followed by three years in the reserve. The enactment of this measure was strongly opposed, especially by the farmers.

ECONOMICS

Industry.—The islanders have been very versatile in adopting new industries when one has begun to fail. When vast shoals of cod were discovered off Newfoundland in the 16th century, fishing fleets from the islands crossed the Atlantic, and the operation of fleets in this way continued for 300 years. In 1872 the Jersey boats alone numbered more than 400.

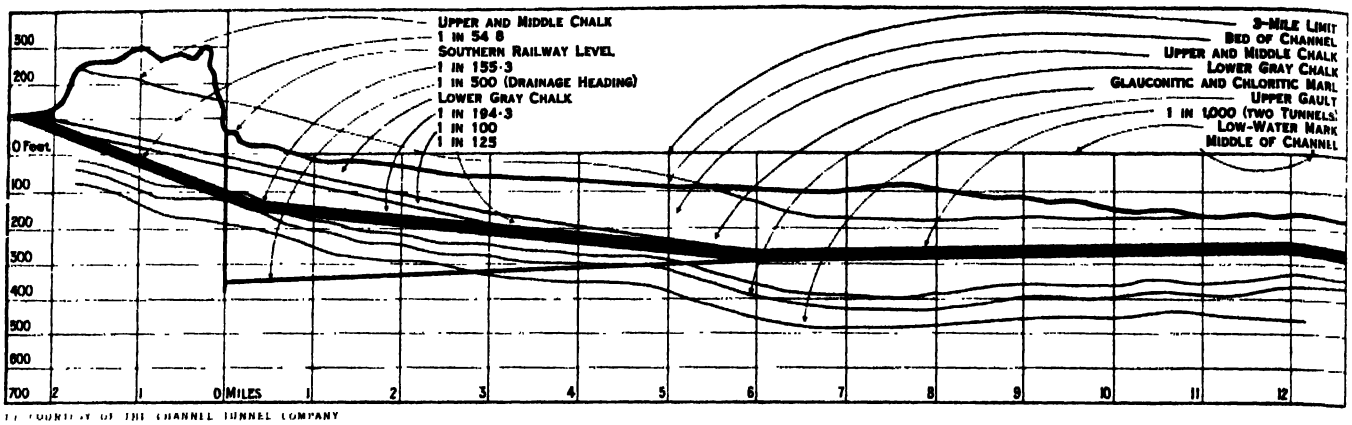
From Elizabeth I's time knitting woollen "guernseys," "jerseys" and stockings became a major occupation. In 1685 Dumaresq declared that "At least half the people in Jersey depend upon the manufacture of stockings" and in Alderney "they adict themselves to the manufacture of knit waistcoats, whereby they neglect fishing."

About this time Guernsey was exporting 4,000 pairs of stockings weekly.

During the American and Napoleonic Wars much wealth was won by privateering, and a roaring trade was done with English smugglers, who loaded their ships with tobacco and spirits to be furtively landed in England. And, till wooden ships went out of use, shipbuilding yards in Jersey and Guernsey were constantly busy.

But the basic industry has always been agriculture. There is, however, a difference between the islands. Guernsey's high ground is in the south, so the island slopes toward the north; Jersey slopes southward. This southerly tilt enables Jersey to grow most of its crops in the open, whereas there are many acres of hothouses in Guernsey.

Jersey growers concentrate mainly on early potatoes and tomatoes. The chief exports of Guernsey are tomatoes, flowers and grapes. In addition each island is famous for its pedigreed cattle. Jersey and Guernsey cows (the breeds are not identical) fetch high prices in England and the United States, and even in New Zealand.



Coinage.—Jersey and Guernsey each has a copper coinage of its own. Up to 1830 they used French *livres tournois, sous* and *liards*, but in that year Guernsey issued coins of 1 *double*, 4 *doubles*, and 8 *doubles*, the 1 *double* being the equivalent of the French *liard* and the 8 *doubles* of the English penny. The bailiwick of Guernsey has its own £1 and 10 *s.* notes.

In 1834 Jersey adopted the English system of pounds, shillings and pence, and in 1841 it too put into circulation its own pence, halfpence and farthings, however, to equate the new currency with the old, the farthing was regarded as worth two *liards*, and that made the penny only worth $\frac{1}{13}$th of a shilling, which remained its value till 1877, when its inscription was changed to "$\frac{1}{12}$th of a shilling."

CHANNELL, SIR WILLIAM FRY (1804–1873), British jurist, was born on Aug. 31, 1804. His education was fragmentary, but he was an avid reader in his youth and prepared for a legal career, being called to the bar in 1827. In 1840 he was made a sergeant of the court of common pleas, and in 1857 he was appointed to the court of exchequer, being knighted that same year. Illness forced his retirement from the bench in Jan. 1873, and he could not accept formal appointment as a member of the privy council. Shortly thereafter, on Feb. 26, 1873, he died in London.

CHANNEL TUNNEL (ENGLISH CHANNEL). A tunnel under the English channel was first proposed by a French engineer, Thomé de Gamond (1807–75), who submitted a scheme for it to Napoleon III in 1856. He was joined in his work by the British engineers, Isambard Brunel, Joseph Lock and Robert Stephenson, and later by Sir John Hawkshaw. The proposal was seriously considered by the railway companies on both sides of the channel, and a convention with the French government to regulate it was signed in 1875. Then the bitter rivalry of the South Eastern and the Chatham and Dover railway companies created difficulties and the scheme became a political question. W. E. Gladstone was a keen supporter, as were John Bright, Lord Lansdowne and Lord Salisbury, while Joseph Chamberlain and the war office opposed. The subject was referred to a joint select committee of the commons, which considered many reports by

FIG 1 - ENGLISH HALF, SHOWING SECTION OF TUNNEL FROM BEHIND DOVER CLIFFS TO MID-CHANNEL. THE TUNNEL WOULD INCLUDE TWO TUBES IN THE IMPERMEABLE GRAY CHALK, AND DRAINAGE HEADING WITH SHAFT ON THE SHORE, WHERE THE WATER WOULD BE PUMPED UP INTO THE SEA

generals favouring the scheme and a memorandum by Lord Wolseley strongly resisting it. The committee decided against the proposal by 6 to 4, Lord Lansdowne, the chairman, voting for it. Thereafter succeeding British governments all opposed the scheme.

After Louis Blériot had flown the channel in 1909, a Channel

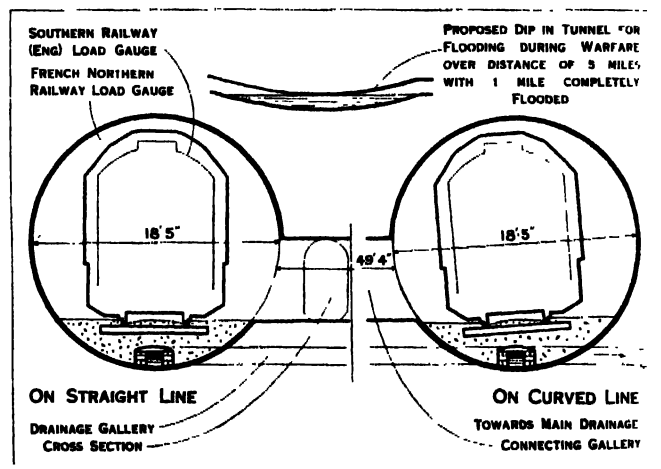

FIG. 2.—CROSS SECTIONS OF THE PROPOSED CHANNEL TUNNEL

Tunnel committee was formed in the house of commons, under the chairmanship of Sir Arthur Fell, which ultimately numbered more than 400 members of parliament. The Labour party joined en masse and Herbert Asquith promised to have inquiries made. World War I broke out and nothing could be done. After the war David Lloyd George promised to make more inquiries. Andrew Bonar Law and Stanley Baldwin did nothing. James Ramsay MacDonald, in July 1924, offered to consult all the living ex-prime ministers. The five met and rejected the scheme, although a two to one majority of M.P.'s supported it.

So the Channel tunnel scheme was shelved again but the idea did not die.

The French Channel Tunnel company had received a concession from their government and could resume work at any time but the English Channel Tunnel company could do nothing further without an act of parliament, to which no British government had yet consented by the mid-1950s.

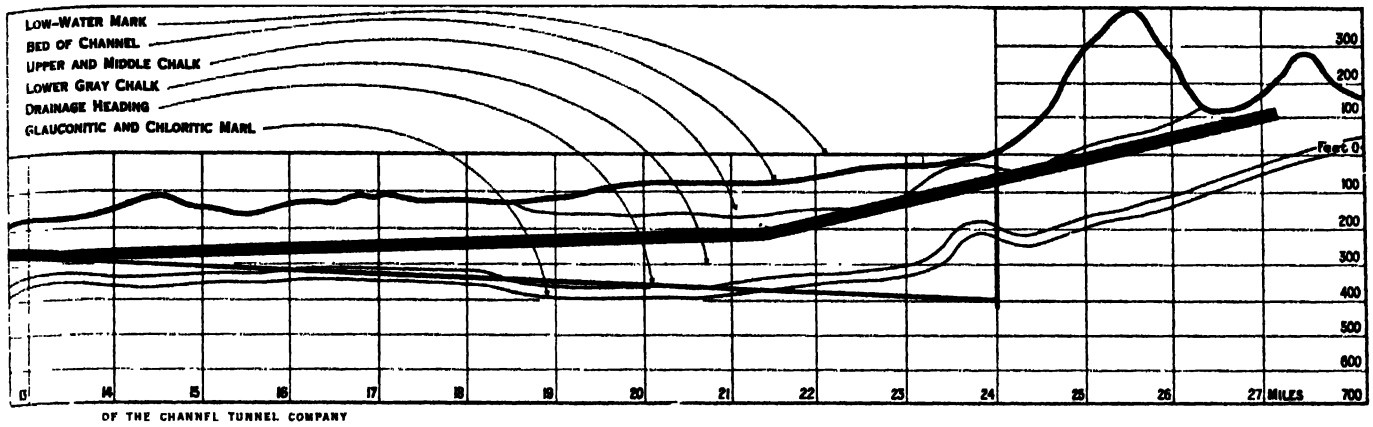
It is a great project, comparable only with the Suez and Panama canals, but its story has reflected little credit on any but the engineers who perfected the scheme.

BY COURTESY OF THE CHANNEL TUNNEL COMPANY

FIG 3 —DETAILS OF THE PROPOSED TWIN CHANNEL TUNNEL, SHOWING CONNECTING GALLERY AND DRAINAGE HEADING, ALSO DIFFERENCE IN THE SIZE OF ENGLISH AND CONTINENTAL ROLLING-STOCK

The proposals involve a double tunnel more than 30 mi. long of which more than 20 mi. would be under the open sea. Two tunnels would be driven about 50 ft. apart, each about 20 ft. in diameter, and the two connected by frequent cross galleries. The tunnel would run from near Wissant in France, between Boulogne and Calais to behind the Shakespeare cliffs in England between Dover and Folkestone.

Drainage would be effected by a smaller 10-ft.-diameter tunnel at a lower level than the railway tunnels and discharging into shafts on each side of the channel from which the seepage would be pumped up into the sea. The tunnels, which would be steel lined would be driven throughout in the bed of gray chalk which extends under the channel and outcrops on both sides. Two exploratory headings, each $1\frac{1}{4}$ mi. long, were driven from Sangatte near Calais and from the shore under Shakespeare cliff where the old works can be seen from the Folkestone to Dover railway. Although these headings are unlined, the percolation of water into them has been negligible.



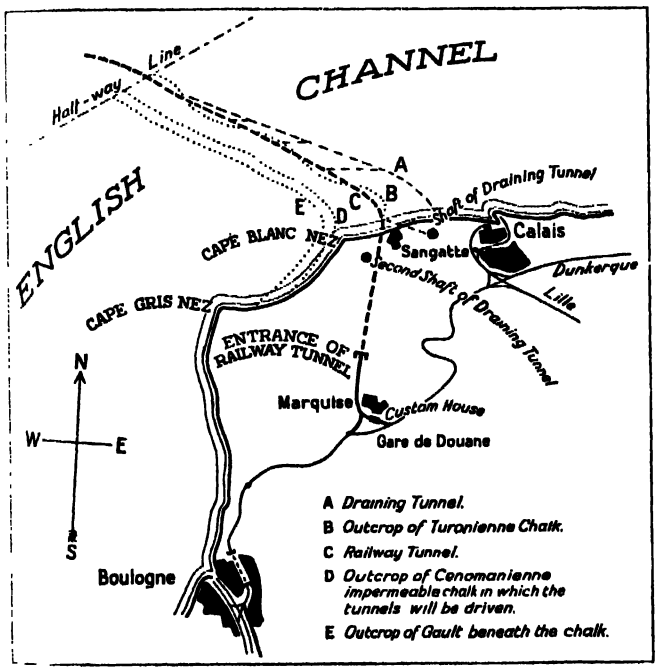


FIG 4.—LONGITUDINAL SECTION OF FRENCH HALF, SHOWING LEVEL OF TUNNEL FROM MID-CHANNEL TO THE MOUTH OF THE TUNNEL IN FRANCE, HIND CAP BLANC NEZ, BETWEEN CALAIS AND BOULOGNE, WITH DRAINAGE HEADING AND SHAFT FOR PUMPS ON SEASHORE NEAR SANGATTE

The cost of the scheme was estimated before World War II at about £25,000,000 to £30,000,000, but engineering costs increased greatly afterward. Also against the scheme has been the great increase in air transport, as this has, to some extent served the purpose for which the tunnel was designed. Nevertheless the conception of the channel tunnel remains unquestionably one of the

greatest engineering proposals in the world. The scheme was reconsidered during the early days of World War II, but not proceeded with as the period of construction would have been too great to make it practicable as a war measure.

CHANNING, EDWARD TYRRELL (1790–1856), U.S. editor, was born at Newport, R.I., on Dec. 12, 1790, the brother of William Ellery and Walter Channing (*qq.v.*). He studied at Harvard university and was admitted to the bar in 1813. His interests lay rather in journalism, however, and in May 1818 he became editor of the young *North American Review*, remaining in this post until Oct. 1819, when he became professor of rhetoric at Harvard. At Harvard he wrote little, but his influence as a teacher was great; among his students was Edward Everett Hale. Channing retired from the Harvard faculty at the age of 60 and died Feb. 8, 1856, at Cambridge, Mass.

CHANNING, WALTER (1786–1876), U.S. physician, was born at Newport, R.I., the brother of William Ellery and Edward Tyrrell Channing (*qq.v.*). He studied at Harvard university and at the medical school of the University of Pennsylvania, Philadelphia, Pa., where he received his M.D. in 1809. He then studied medicine in Europe before returning to Boston, Mass., in 1812 to set up practice as an obstetrician.

Three years later he was appointed first professor of obstetrics at Harvard, where later he was dean of the medical school (1819–47). In 1847 he first used ether as an anaesthetic in deliveries, and in the next year reported its successful employment in more than 500 labour cases.

Channing was one of the founders of the Boston Lying-In hospital in 1832 and was a co-editor of the *Boston Medical and Surgical Journal* From 1822 to 1825 he was librarian of the Massachusetts Medical society, and from 1828 to 1840 acted as treasurer of the society.

CHANNING, WILLIAM ELLERY (1780–1842), American divine and philanthropist, was born in Newport, R.I., April 7, 1780. Channing seemed to have inherited from his father sweetness of temper and warmth of affection, and from his mother that strong moral discernment and straightforward rectitude of purpose and action which formed striking features of his character.

He prepared for college in New London under the care of his uncle, the Rev. Henry Channing, to this period tracing the beginning of his spiritual life, and in 1794 entered Harvard college. In his college vacations he taught at Lancaster, Mass., and in term time he stinted himself in food to save time for study—an experiment which produced acute dyspepsia.

Nevertheless, he felt that he got little good from his college course.

After graduating in 1798, he lived at Richmond as tutor in the family of David Meade Randolph, U.S. marshal for Virginia. He returned "a thin and pallid invalid," to spend a year and a half in Newport, which had always delighted him by its beauty, and in 1802 went to Cambridge as regent (or general proctor) in Harvard; in the autumn of 1802 he began to preach. On June 1, 1803, he was ordained pastor of the Federal street Congregational church in Boston.

Channing did not become known as "the apostle of Unitarianism" until after his sermon preached at the ordination of the Rev. Jared Sparks in 1819 and the publication of his articles in *The Christian Disciple*, "Objections to Unitarian Christianity Considered" and "The Moral Argument Against Calvinism." He took a keen interest in all public questions; and in 1816 he preached

a sermon on war which led to the organization of the Massachusetts peace society. His sermon on "Religion, a Social Principle," helped to procure the omission from the state constitution of the third article of Part I., which made compulsory a tax for the support of religious worship. In Aug. 1821 he undertook a journey abroad, where he met many distinguished men of letters, including Wordsworth and Coleridge; the latter wrote of him, "He has the love of wisdom and the wisdom of love."

As a result of a visit to the West Indies he began to write his book *Slavery* (1835), in which he asserted that "man cannot be justly held and used as property"; that the tendency of slavery is morally, intellectually, and domestically bad; that emancipation, however, should not be forced on slave-holders by governmental interference, but by an enlightened public conscience. He declined to identify himself with the abolitionists, whose motto was "Immediate Emancipation" and whose passionate agitation he thought unsuited to the work they were attempting. In 1837 he published *Thoughts on the Evils of a Spirit of Conquest, and on Slavery: A Letter on the Annexation of Texas to the United States*, addressed to Henry Clay—arguing that the Texan revolt from Mexican rule was largely the work of land-speculators, and of those who resolved "to throw Texas open to slave-holders and slaves"—and warning of its serious consequences. Channing's pamphlet *Emancipation* (1840) dealt with the success of emancipation in the West Indies, as related in Joseph John Gurney's *Familiar Letters to Henry Clay of Kentucky* (1840). In 1842 he published *The Duty of the Free States; or Remarks Suggested by the Case of the Creole*, a careful analysis of the letter of complaint from the American to the British government, and a defence of the position taken by the British government. On Aug. 1, 1842, he delivered at Lenox (Mass.) an address celebrating the anniversary of emancipation in the British West Indies. Two months later, Oct. 2, 1842, he died at Bennington, Vermont.

Physically, Channing was short and slight; his eyes were unnaturally large; his voice wonderfully clear. He was not a great pastor, and lacked social tact, but by the few who knew him well he was almost worshipped. His sermons were noted for their rare simplicity and gracefulness of style. To the name "Unitarian" Channing objected strongly, thinking "unity" as abstract a word as "trinity" and as little expressing the close fatherly relation of God to man. It is to be noted that he strongly objected to the growth of "Unitarian orthodoxy" and its increasing narrowness. Channing believed in historic Christianity and in the story of the resurrection, "a fact which comes to me with a certainty I find in few ancient histories," although he held that the Scriptures were not inspired but merely records of inspiration. In the controversies into which he was forced he continually displayed the greatest breadth and catholicity of view. The differences in New England churches he considered were largely verbal, and he said that "would Trinitarians tell us what they mean, their system would generally be found little else than a mystical form of the Unitarian doctrine." His opposition to Calvinism was so great, however, that even in 1812 he declared "existence a curse" if Calvinism be true. Possibly his boldest and most elaborate defence of Unitarianism was his sermon on *Unitarianism most favourable to Piety*, preached in 1826, and the election sermon of 1830 was his greatest plea for spiritual and intellectual freedom.

Channing's reputation as an author was probably based largely on his publication in *The Christian Examiner* of *Remarks on the Character and Writings of John Milton* (1826), *Remarks on the Life and Character of Napoleon Bonaparte* (1827–28), and an *Essay on the Character and Writings of Fénelon* (1829). An *Essay on Self-Culture* introduced Franklin lectures delivered in Boston in 1838. Channing was an intimate friend of Horace Mann, and his views on the education of children are stated by Elizabeth Palmer Peabody to have anticipated those of Froebel. His *Complete Works* have appeared in various editions since 1841.

See the *Memoir* by W. H. Channing (1848); Elizabeth P. Peabody, *Reminiscences of the Rev. William Ellery Channing, D.D.* (1880), intimate but inexact; J. W. Chadwick, *William Ellery Channing, Minister of Religion* (1903); W. M. Salter, "Channing as a Social Reformer," *Unitarian Review* (March 1888); and C. W. Eliot, *Four American Leaders* (1906).

CHANSONS DE GESTE, the name given to the epic chronicles which take so prominent a place in the literature of France from the 11th to the 15th century. Gaston Paris defined a chanson de geste as a song the subject of which is a series of historical facts or *gesta*. These facts form the centre around which are grouped sets of poems, called cycles. It seems probable that as early as the 9th century epic poems began to be chanted by the itinerant minstrels, known as jongleurs. It is conjectured that in a base Latin fragment of the 10th century we possess a translation of a poem on the siege of Girona. Gaston Paris dates from this lost epic the open expression of what he calls "the epic fermentation" of France. The earliest existing chanson de geste is also by far the noblest and most famous, the *Chanson de Roland* (*see* ROLAND, LEGEND OF). It is in the crowd of looser and later poems, less fully characterized, that we can best study the form of the typical chanson de geste. These epics were national and historical; their anonymous writers composed them spontaneously, to a common model, with little regard to the artificial niceties of style. The earlier examples are monotonous, primitive and superficial. Two great merits, however, all the best of these poems possess, force and lucidity; they are full of Gallic pride, they breathe the spirit of an indomitable warlike energy. All their figures belong to the same social order of things, and all illustrate the same fighting aristocracy. The moving principle is that of chivalry, and what is presented is, invariably, the life of a mediaeval soldier.

Perhaps the most important cycle of chansons de geste was that which was collected around the name of Charlemagne, and was known as the *Geste du roi*. A group of this cycle dealt with the history of the mother of the emperor, and with Charlemagne himself down to the coming of Roland. To this group belong *Bertha Greatfoot* and *Aspremont*, both of the 12th century, and a variety of chansons dealing with the childhood of Charlemagne and of Ogier the Dane. A second group deals with the struggle of Charlemagne with his rebellious vassals. This includes *Girart de Viane* and *Ogier the Dane*, both of the 13th century or late 12th. A third group follows Charlemagne and his peers to the East. It is in the principal of these poems, *The Pilgrimage to Jerusalem*, that Alexandrine verse first makes its appearance in French literature. This must belong to the beginning of the 12th century. A fourth group, antecedent to the Spanish war, is of *c.* 1200; it includes *Aiquin*, *Fierabras* and *Otinel*. The fifth class discusses the war in Spain, and it is to this that *Roland* belongs; there are minor epics dealing with the events of Roncevaux, and independent chansons of *Gui de Bourgogne*, *Gaidon* and *Ansëïs de Carthage*. A sixth and last group deals with events up to the death of Charlemagne; this contains *Huon de Bordeaux* and a vast number of poems of minor importance.

Another cycle is that of Duke William Shortnose, *La Geste de Guillaume*. It includes the very early and interesting *Departure of the Aimeri Children*, *Aliscans* and *Rainoart*. This cycle deals with the heroes of the South who remained faithful to the throne. The poems belonging to it are numerous. These chansons find their direct opposites in those which form the great cycle of *La Geste de Doon de Mayence*, sometimes called "la faulse geste," because it deals with the feats of the traitors, of the rebellious family of Ganelon. This is the geste of the Northmen, always hostile to the Carlovingian dynasty. It comprises some of the most famous of the chansons, in particular *Parise la duchesse* and *The Four Sons of Aymon*. Several of its sections are the production of a known poet, Raimbert of Paris. From this triple division of the main body of the chansons are excluded certain poems of minor importance.

All the best of the early chansons de geste are written in ten-syllable verse, divided into stanzas or *laisses* of different length, united by a single assonance. Rhyme came in with the 13th century, and had the effect in languid bards of weakening the narrative; the sing-song of it led at last to the abandonment of verse in favour of plain historical prose.

See G. Paris, *Histoire poétique de Charlemagne* (1865) and *La Littérature française au moyen âge* (1890); P. Meyer, *Recherches sur l'épopée française* (1867); A. Longnon, *Les Quatre Fils Aimon*, etc. (1879); L. Gautier, *Les Epopées françaises* (4 vols., 1878–94).

CHANT, the name given to the tunes used in the English Church since the Reformation for the psalms and canticles (Fr. *chant*, from Lat. *cantare*, to sing). For the chant or *cantus firmus* of the Roman Church *see* PLAINSONG. In the English chant each section consists of a reciting note of indefinite length, followed by a phrase in regular time called a "mediation." Chants are "single," if written for one verse only, "double," if for two. "Quadruple" chants for four verses have also been written.

CHANTABUN or CHANDABURI, a town on the east side of the Gulf of Siam, Thailand, in 102° 6′ E., 12° 38′ N. Chantabun changvad (district) has an area of 2,301 sq.mi., and a pop. (1937) of 100,938, divided among Thai, Cambodians, Chinese and minor races. It lies about 12 mi. from the sea on a river navigable for small craft. Rice is the leading crop, but the 1,300 ac of pepper produce three-fourths of the country's 200-ton annual output. There is trade in rubies, sapphires, cardamoms and rosewood. As part of the nationwide road-building program inaugurated about 1935, Chantabun was connected with Bangkok by a 180-mi. all-weather highway. An extension leads to Trat, close to the Indo-China frontier. In 1905 it was made headquarters of a high commissioner of a circle. Circles were abolished in 1932. Roman Catholic missionaries have been active since the 17th century, and converts are numerous.

CHANTADA, a city of northwestern Spain, in Lugo province on the left bank of the Rio de Chantada, a small right-hand tributary of the river Miño, and on the main road from Lugo to Orense. Pop. (1940) 1,552 (mun., 15,127). Chantada is the chief town of the fertile region between the Miño and the heights of El Faro. Despite the lack of railway communication, it has a thriving trade in grain, flax, potatoes and dairy produce.

CHANTAL, JANE FRANCES, BARONESS DE (1572–1641), French saint and founder of the Order of the Visitation, was born Jan. 28, 1572, at Dijon, the daughter of the president of the *parlement* of Burgundy. At the age of 20 she married Baron de Chantal, but on his death, four years later, resolved to devote herself to the religious life. In 1604 she met St. Francis de Sales, and her four children being provided for, she went to Annecy where she founded the Congregation of the Visitation in June 1610. She was canonized in 1767, her feast being observed Aug. 21.

See F. M. de Chaugy, *Ste. J. F. de Chantal*, 8 vols. (1874–79); H Bremond, *Sainte Chantal* (1912); and *The Spirit of St. J. F. de Chantal as shown in her Letters* (1922).

CHANTARELLE, an edible fungus, known botanically as *Cantharellus cibarius* (family, Agaricaceae) found in woods in summer. It is golden yellow, somewhat inversely conical in shape and about 2 in. broad and high. The cap is flattened above with a central depression and a thick-lobed irregular margin. Running down into the stem from the cap are a number of shallow thick gills. The substance of the fungus is dry and opaque with a peculiar smell suggesting ripe apricots or plums. The flesh is whitish tinged with yellow. The chantarelle is sold in the markets of Europe, where it forms a regular article of food, but seems little known in Great Britain; it is common in coniferous woods in northeastern United States and Canada. Before being cooked they should be allowed to dry, and then thrown into boiling water.

Care should be taken to distinguish the true chantarelle from the false Chantarelle (*C. aurantiacus*), a closely related species which is suspected of having caused poisoning. The latter species is more orange in colour, with thinner, broader and closer gills.

CHANTAVOINE, HENRI (1850–1918), French man of letters, was born at Montpellier on Aug. 6, 1850, and died at Caluire (Rhône) on Aug. 15, 1918. He was associated with the *Nouvelle Revue* from its foundation in 1879, and he joined the *Journal des débats* in 1884. His poems include *Poèmes sincères* (1877), *Satires contemporaines* (1881), *Ad memoriam* (1884), *Au fil des jours* (1889).

CHANTILLY, a town of northern France, in the department of Oise, 25 mi. N. of Paris on the Northern railway to St. Quentin. Pop. (1936) 5,054. It is situated to the north of the forest of Chantilly and is one of the favourite Parisian resorts. Its name was long associated with the manufacture, now decayed, of lace and blonde; it is still more celebrated for its château and its park (laid out originally in the 17th century), and as the scene of the annual races of the French Jockey Club. The château consists of the palace built from 1876 to 1885 and of an older portion adjoining it known as the châtelet. In the reign of Charles VI. the lordship belonged to Pierre d'Orgemont, chancellor of France. In 1484 it passed to the house of Montmorency, and in 1632 to the house of Condé. Louis II., prince de Condé, enjoyed here the society of La Bruyère, Racine, Molière, La Fontaine, Boileau and others. The stables close to the racecourse were built from 1719 to 1735 by the duke of Bourbon. The grand château was destroyed about the time of the Revolution, but the châtelet still remains one of the finest specimens of Renaissance architecture in France. The château d'Enghien, facing the entrance to the grand château, was built in 1770 as a guest-house. In 1830 the estate passed into the hands of Henri, duc d'Aumale, fourth son of Louis Philippe. In 1852 the house of Orléans was declared incapable of possessing property in France, and Chantilly was accordingly sold by auction, but passed back into the hands of the duc d'Aumale who built the palace, on the foundations of the grand château. He installed in the châtelet a valuable library and a collection of paintings. In 1886 he gave the park and château with its collections to the Institute of France in trust for the nation, reserving to himself only a life interest.

CHANTREY, SIR FRANCIS LEGATT (1781–1841), English sculptor, was born on April 7, 1781, at Norton, near Sheffield. After receiving lessons in carving and painting, Chantrey went to try his fortune in Dublin and Edinburgh, and finally (1802) in London. He exhibited pictures at the Academy for some years from 1804, but from 1807 onwards devoted himself mainly to sculpture. His first imaginative work in sculpture was the model of the head of Satan, which was exhibited at the Royal Academy in 1808. He afterwards executed for Greenwich hospital four colossal busts of the admirals Duncan, Howe, Vincent and Nelson; and the next bust which he executed, that of Horne Tooke, procured him commissions to the extent of £12,000. He received many honours, was elected R.A. in 1818, and received a knighthood in 1835. He died suddenly on Nov. 25, 1841.

His principal works are the statues of Washington in the State House at Boston, U.S.A.; of George III. in the Guildhall, London; of George IV. at Brighton; of Pitt in Hanover Square, London; of James Watt in Westminster Abbey; of Canning in Liverpool; of Lord President Blair and Lord Melville in Edinburgh. Of his equestrian statues the most famous are those of Sir Thomas Munro in Calcutta and the duke of Wellington in front of the London Exchange. But the finest of Chantrey's works are his busts and his delineations of children. The figures of two children asleep in each other's arms, which form a monumental design in Lichfield cathedral, have always been admired for beauty, simplicity and grace. Allan Cunningham and Weekes were his chief assistants, and were indeed the active executants of many works that pass under Chantrey's name. *See* A. J. Raymond, *Life and work of Sir Francis Chantrey* (1904); for his will *see* CHANTREY BEQUEST.

CHANTREY BEQUEST. By the will dated Dec. 31, 1840, Sir Francis Chantrey (*q.v.*), left his whole residuary personal estate after the decease or on the second marriage of his widow (less certain specified annuities and bequests) in trust for the president and trustees of the Royal Academy (or in the event of the dissolution of the Royal Academy, to such society as might take its place), the income to be devoted to the encouragement of British fine art in painting and sculpture only, by "the purchase of works of fine art of the highest merit . . . that can be obtained." The funds might be allowed to accumulate for not more than five years; works by British or foreign artists might be acquired, so long as such works were entirely executed in Great Britain. The prices were to be "liberal," and no sympathy for an artist or his family was to influence the selection or the purchase of works, which were to be acquired solely on the ground of intrinsic merit. No commission or orders might be given: the works must be finished before purchase. An annual sum of £300 and £50 was to be paid to the president of the Royal Academy and the secretary respectively, for the discharge of their duties in

carrying out the provisions of the will.

Lady Chantrey died in 1875, and two years later the fund became available for the purchase of paintings and sculptures. The capital sum amounted to £105,000. Galleries in the Victoria and Albert Museum at South Kensington were at first used, until in 1898 the Royal Academy arranged with the Treasury for the transference of the collection to the National Gallery of British Art, which had been erected by Sir Henry Tate at Millbank.

A growing discontent with the interpretation by the Royal Academy of the terms of the will found forcible expression in the press in 1903, and a debate in the House of Lords led to the appointment of a select committee of that House (June to Aug. 1904). Its report made recommendations with a view to the prevention of certain former errors of administration, but dismissed other charges against the Academy. A memorandum was issued by the Royal Academy (Feb. 1905) disagreeing with certain recommendations, but allowing others.

See *The Administration of the Chantrey Bequest*, by D. S. MacColl (1904), a highly controversial publication; *Chantrey and His Bequest*, by Arthur Fish, a complete illustrated record of the purchases, etc. (1904); *The Royal Academy, its Uses and Abuses*, by H. J. Laidlay (1898), controversial; *Report from the Select Committee of the House of Lords on the Chantrey Trust; together with the Proceedings of the Committee, Minutes of Evidence and Appendix* (1904).

CHANT ROYAL, one of the fixed forms of verse invented by the ingenuity of the poets of mediaeval France. It is composed of five verses, identical in arrangement, of 10 or 11 lines each, and an envoi of 5, 6 or 7 lines. All the verses are written on the five rhymes in the first verse, the entire poem, therefore, consisting of 60 lines or more, in the course of which five rhymes are repeated. It has been conjectured that the chant royal is an extended ballade, or a ballade conceived upon a larger scale; but which form preceded the other appears to be uncertain. On this point Henri de Croï, who wrote about these forms of verse in his *Art et science de rhétorique* (1493), throws no light. He dwells, however, on the great dignity of what he calls the "Champt Royal," and says that those who defy with success the ardour of its rules deserve crowns and garlands for their pains. Étienne Pasquier (1529–1615) points out that the chant royal, by its length and rigidity, is better fitted than the ballade for solemn and pompous themes. In early French literature, the most admired chants royaux are those of Clément Marot; his *Chant royal chrestien*, with its refrain

Santé au corps, et Paradis à l'âme,

was celebrated. Théodore de Banville defines the chant royal as essentially belonging to ages of faith, when its subjects could be either the exploits of a hero of royal race or the processional splendours of religion. La Fontaine was the latest of the French poets to attempt the chant royal, until it was resuscitated in modern times.

This species of poem was unknown in English mediaeval literature and was only introduced into Great Britain in the last quarter of the 19th century. The earliest chant royal in English was that published by Edmund Gosse in 1877, "The Praise of Dionysus."

In the middle ages the chant royal was largely used for the praise of the Virgin Mary. Eustache Deschamps (1340–1410) distinguishes these Marian chants royaux, which were called "serventois," by the absence of an envoi. These poems are first mentioned by Rutebeuf, a *trouvère* of the 13th century. The chant royal is practically unknown outside French and English literature.

CHANTRY, a small chapel in or adjoining a church, endowed for maintaining priests to chant masses for the soul of the founder or of some one named by him. It generally contained the founder's tomb and had an entrance from the outside for the chantry priest. The word is applied either to the endowment funds or to the chapel itself.

CHANUTE, a city of Neosho county, Kansas, U.S.A., 120 mi. S.S.W. of Kansas City, near the Neosho river. It is on federal highways 59, 169 and state highways 39 and 57. It is served by the Missouri-Kansas-Texas and the Santa Fe railways. Pop. (1950) 10,241. Chanute is in the midcontinent oil and gas field and is surrounded by a farming and fruit-growing country. Shale and clay are found near by. Chanute is headquarters of a division of the Atchison, Topeka and Santa Fe railway system. The principal industries are: refineries, railway shops; brick, tile, cement and oil-field machinery manufactures; dress, broom, mattress and boiler factories; and machine and tank shops.

Four towns—New Chicago, Tioga, Chicago Junction and Alliance—founded here about 1870, were consolidated in 1872, and named after Octave Chanute (b. 1832), civil engineer and aeronautist, who was the engineer of the railway then under construction. Natural gas and oil were discovered in 1899.

CHANZY, ANTOINE EUGÈNE ALFRED (1823–1883), French general, was born at Nouart (Ardennes) on March 18, 1823. The son of a cavalry officer, he was educated at the naval school at Brest, but enlisted in the artillery, and was commissioned in the Zouaves in 1843. Although he acquired an excellent professional reputation during war service in Algeria and in Lombardy, he was in bad odour at the War Office on account of suspected contributions to the press, and at the outbreak of the Franco-German War was refused a brigade command. After the revolution, however, the government of national defence gave him command of the XVI. Corps of the army of the Loire. (For the operations of the Orleans campaign which followed, *see* FRANCO-GERMAN WAR.) After the second battle of Orleans and the separation of the two wings of the French army, Chanzy was appointed to command that in the west, designated the second army of the Loire. He displayed conspicuous moral courage in the fighting from Beaugency to the Loire, in his retreat to Le Mans, and in retiring to Laval behind the Mayenne. He was made a grand officer of the Legion of Honour, and was elected to the National Assembly. At the beginning of the commune, Chanzy, then at Paris, fell into the hands of the insurgents, by whom he was liberated on giving his parole not to serve against them. A ransom of £40,000 was also paid by the Government for him. In 1872 he became a member of the committee of defence and commander of the VII. Army Corps, and in 1873 was appointed governor of Algeria, where he remained for six years. In 1875 he was elected a life senator, in 1878 received the grand cross of the Legion of Honour, and in 1879, without his consent, was nominated for the presidency of the republic, receiving a third of the total votes. For two years he was ambassador at St. Petersburg (Leningrad). He died suddenly, while commanding the VI. Army Corps at Châlons-sur-Marne, on Jan. 4, 1883, and his remains received a state funeral. He was the author of *La Deuxième Armée de la Loire* (1872).

See J. M. Villefranche, *Histoire du Général Chanzy* (1890).

CHAOS, in the Hesiodic theogony, the infinite empty space which existed before all things (*Theog.* 116, 123). It is not, however, a mere vacuum, being filled with clouds and darkness; from it proceed Erebus and Nyx (Night), whose children are Aether (upper air) and Hemera (Day). In the Orphic cosmogony the origin of all goes back to Chronos, the personification of time, who produces Aether and Chaos. In the Aristophanic parody (*Birds*, 691) the winged Eros in conjunction with gloomy Chaos brings forth the race of birds. The later Roman conception (Ovid, *Metam.* i. 7) makes Chaos the original crude, shapeless

mass, into which the architect of the world introduces order and harmony, and from which individual forms are created. When contrasted with cosmos (the orderly universe) the word has various meanings:—the space between heaven and earth; the underworld and its ruler; the immeasurable darkness; the indefinite in space and time. In modern usage "chaos" denotes a state of disorder and confusion.

CHAPACURAN, a tribe or small group of tribes of South American Indians, regarded on rather slender evidence as constituting an independent linguistic stock. The stock, which comprises the Ites, Pawumwas and other smaller tribes in addition to the Chapacuras, seems to have occupied the whole of the basin of the Rio Blanco in north-eastern Bolivia, together with the Guaporé from the mouth of the Blanco to its confluence with the Mamore, as well as the eastern tributaries of the Guaporé between 12° and 13° S. Lat. The Chapacuras themselves lived on the Rio Blanco and about lake Chitiopa. They were a peaceful, sedentary agricultural folk, whose culture was generally similar to that of the Chiquitos (*q.v.*). The Pawumwas go almost naked, and use the blow-gun with poisoned darts.

See G. de Crequi-Montfort and P. Rivet, *Linguistique Bolivienne; La famille linguistique Capakura* (*J. Soc. Americanistes de Paris* [n. s. vol. x., pp. 119–173); J. D. Haseman, *Some notes on the Pawumwa Indians* (*American Anthropologist* [n.s.], vol. xiv., pp. 333–350).

CHAPAIS, SIR (JOSEPH AMABLE) THOMAS (1858–1946), Canadian lawyer, statesman and historian, was born at St. Denis-de-la-Bouteillerie, Quebec, on March 23, 1858, son of Senator J. C. Chapais, one of the "Fathers of Confederation." Chapais was educated at St. Anne's college, Laval university, and was called to the Quebec bar in 1879. In March 1892 he was called to the legislative council of Quebec, was a minister without portfolio in the Taillon government, and was elected leader of the government in the executive council (Jan. 1893); speaker of the legislative council (April 1895); president of the executive council (May 1896), and minister of colonization and mines (Jan. 1897). He retired from office in May 1897. From 1884 to 1901 Chapais edited *Le Courrier du Canada* of Quebec. In 1907 he was appointed professor at Laval university. He published several works on history and law, including *Cours d'Histoire du Canada, 1760–1814* (8 vols., 1919–35). On Dec. 31, 1919, he was called to the senate of Canada. He was knighted in 1935. He died at St. Denis, Que., on July 15, 1946.

CHAPARRAL, a mixed forest formation of low hard-leaved, stunted trees and shrubs resulting from short, wet, cool winters and long, arid, hot summers. The word is believed to have been derived from *chaparro,* the Spanish name for live oak. Chaparral grows slowly and shrubs 25 years old will usually average not more than 2 or 3 in. in diameter and 5 or 6 ft. in height. This type of forest growth occurs chiefly in southern California in the United States, along the coast of Chile, in Europe and Asia along the Mediterranean and as far east as Turkistan, in Africa near the Cape of Good Hope and on the southern and southwestern coasts of Australia and Tasmania. Its chief economic value lies in its ability to conserve water supply, which it accomplishes below the surface through its root system and above the surface by breaking the force of hot winds and shading the ground to prevent evaporation.

Of the 150 different species of woody plants believed to exist in the chaparral of Southern California 20 dominant types—among them chamise, manzanita, ceanothus, sumac, sage-brush, scrub oak and buckthorn (*qq.v.*)—represent 90% of the growth. In former times the Indians used the nuts, berries and seeds of several of the varieties for food. Some species were once in demand as fuel supply and others are still used for fencing. The bee industry flourishes in the chaparral region, several profusely flowering shrubs, as the black sage, being excellent honey plants. It is estimated that there are 5,500,000 acres of chaparral in the United States. Chaparral formations protect the upper watersheds of the coastal streams in California for a distance of about 450 miles.

CHAPBOOK, the comparatively modern name applied by booksellers and bibliophiles to the little stitched tracts written for the common people and formerly circulated in England, Scotland and the American colonies by itinerant dealers or chapmen, consisting chiefly of vulgarized versions of popular stories, such as *Tom Thumb, Jack the Giant Killer, Mother Shipton,* and *Reynard the Fox*—travels, biographies and religious treatises. Few of the older chapbooks exist. Samuel Pepys collected some of the best and had them bound into small quarto volumes which he called *Vulgaria;* also four volumes of a smaller size, which he lettered *Penny Witticisms, Penny Merriments, Penny Compliments* and *Penny Godlinesses.* The early chapbooks were the direct descendants of the black letter tracts of Wynkyn de Worde. It was in France that the printing-press first began to supply reading for the common people. At the end of the 15th century there was a large popular literature of farces, tales in verse and prose, satires, almanacs, etc., stitched together so as to contain a few leaves, and circulated by itinerant booksellers, known as colporteurs. Most early English chapbooks are adaptations or translations of these French originals, and were introduced into England early in the 16th century. The chapbooks of the 17th century present us with valuable illustrations of the manners of the time; one of the best known is that containing the story of Dick Whittington. In France literature of this kind has been the object of close and systematic study, and *L'Histoire des livres populaires ou de la littérature du colportage* by Charles Nisard (1854) goes deeply into the subject. Amongst English books may be mentioned *Notices of Fugitive Tracts and Chapbooks,* by J O. Halliwell-Phillipps (1849); *Chapbooks of the 18th Century,* by John Ashton (1882), and some reprints by the Villon Society in 1885.

CHAPE, a cover or metal plate, such as the cap upon the needle in the compass, also the transverse guard of a sword which protects the hand (Fr. *chape,* a hood, cope or sheath); also, a support or catch to attach one thing to another, as the hook on a belt to which the sword is fastened; and the tip of a fox's brush.

CHAPEL, a place of religious worship, either a subordinate division of a church, or a separate building distinguished from a church by the special conditions of its foundation or use. *Capella,* the diminutive of *cappa,* a cloak, was the name given to the shrine in which the cloak (*cappa brevior*) of St. Martin was kept and carried about by the Frankish kings on their journeys, when oaths were taken on it. This peculiar use was transferred to any sanctuary containing relics, the priest of which was called *capellanus* or chaplain. By a further extension, the word was identified with all places of worship which were not mother churches (*ecclesiae matrices*), so as to include a large number of miscellaneous foundations. Most nearly akin to the original meaning is the application of the term to the oratories attached to royal residences. Thus the Sainte Chapelle, the palace chapel at Paris, consecrated in 1248, was built by St. Louis to enshrine the relic of the Crown of Thorns, ransomed by him from the Venetians, who held it in pawn from John of Brienne, the Latin emperor of the East. In the next century, chapels were founded by princes of the French royal house at Bourges, Riom and elsewhere for which the same title was adopted. Such chapels royal were usually founded as collegiate establishments, like Edward III.'s chapels of St. Stephen at Westminster and St. George at Windsor. Collegiate chapels were also founded by prelates and noblemen in connection with their castles and manor-houses, such as the chapel of St. Mary and the Holy Angels at the gate of the palace at York, founded by Archbishop Roger (1154–81), and that of St. Elizabeth before the gate of Wolvesey Castle at Winchester, founded by Bishop John of Pontoise (1282–1304).

The chapel of the castle or manor-house, however, was generally served by a single domestic chaplain. For oratories in connection with private houses an episcopal licence was required, so as to safeguard the rights of the churches in whose parishes they were established. Though frequently within the house itself, they were also erected as separate buildings, and some, which served as churches for the lord of the manor and his tenants, acquired the status of free chapels, which implied exemption from parochial and archidiaconal, and occasionally, though not always, from episcopal jurisdiction. Certain churches, in the patronage of the Crown or

owing their foundation to the king, were regarded as royal free chapels and free chapels on manors probably originated in the grant of special privileges to their owners by the Crown. In time, such free chapels, governed by rectors, sometimes lost their peculiar character and were reckoned as parish churches; but, where the status of a free chapel remained, their incumbents were held to be without cure of souls.

Parish Chapels.—More numerous, however, than free chapels were the chapels in outlying hamlets of large parishes, maintained by the inhabitants and served daily, or on certain days in the week, by chaplains provided at the expense of the parochial incumbent. Some of these, which, as time went on, acquired rights of baptism and burial, were parochial chapels; others, merely chantry chapels in small villages, without such rights, were, properly speaking, chapels of ease. The origin of such foundations was usually the difficulty experienced by the inhabitants in attending the mother church in bad weather, when the streams were swollen and the roads impassable. In Leicestershire, early in the thirteenth century, there were more than a hundred of these dependent chapels in about two hundred parishes, and the proportion elsewhere was not very different.

Subordinate Buildings.—The idea of a chapel as a subordinate or dependent building is implied by its use for the areas appropriated to the minor altars within or projecting from the walls of a church. The services held in these were called chantries (*cantariae*), and, by a transference of ideas to which there are many parallels in mediaeval usage, the chapels themselves were often known as chantries. Of the use of chapel to signify the oratory of a private establishment, the most familar examples are the chapels of colleges at Oxford and Cambridge. Similarly the places of worship in hospitals, almshouses, etc., are called chapels, as well as those which, like chapels of cemeteries, are generally restricted to some special use. Proprietary chapels, founded in London and other English towns during the eighteenth and early nineteenth centuries, were established, with a licence for divine service, by private individuals or groups of trustees. The growth of Nonconformity, however, gave the word a particular application to dissenting places of worship. In Ireland the term has clung persistently to those of the Roman Church, a survival of an old use which in England was derived from the chapels or religious establishments maintained by Henrietta Maria and other Roman Catholic queens. But, apart from this, the modern tendency is to abandon the employment of the word for special classes of religious building, and to give the title church to all indiscriminately.

There are many instances in mediaeval wills and inventories of the application of the term chapel to sets of vestments and altar furniture, as constituting the necessary fittings of a private oratory. Another transference of the sense occasionally found is from the chapel itself to the collective members of the foundation.

(A. H. T.)

CHAPEL. In the printing trade, the name of the fellowship of compositors (and, nowadays, of all crafts) in a printing works. The president is termed the "father of the chapel." In the United States he is called "the chairman." The name chapel is used not only of the fellowship itself but of the meetings which it holds. At these meetings, the chapel discusses such things as the general welfare of the body, the conditions of work, relations with employers, and trade union matters.

The accepted version of the origin of the use of the word chapel in this connection is that it is derived from the fact that Caxton first set up his press in or near Westminster Abbey. Writing in 1716, Myles Davies, in his *Athenae Britannicae* says, "William Caxton first practis'd Printing in the Abbey of Westminster, A.D. 1471, thence a Printing-Room came to be call'd a Chappell amongst our Printers." Another explanation is offered by Joseph Moxon, who in his *Mechanick Exercises* (1683) says, "Every Printing-house is by the Custom of Tune out of mind, called a Chappel: and all the Workmen that belong to it are Members of the Chappel: and the oldest Freeman is Father of the Chappel. I suppose this stile was originally conferred upon it by the courtesie of some great Churchman, or men (doubtless when Chappels were in more veneration than of late years they have been here in England), who for the Books of Divinity that proceeded from a Printing-house gave it the Reverend Title of Chappel."

CHAPELAIN, JEAN (1595–1674), French poet and man of letters, was born in Paris and spent 17 years in the service of M. de la Trousse, grand provost of France. He was employed by Cardinal Richelieu in the organization of the Académie Française. In 1632, in a conversation with the cardinal, he had laid down the canon of the unities of time and space which should govern the drama. The unities had already been advocated by Jules-César Scaliger (*Art poétique*, 1561), and by the abbé d'Aubignac (*Pratique du théâtre*, 1657), but the doctrine appears to have been unfamiliar to Richelieu, who invited Chapelain to draw up *Les Sentiments de l'Académie sur "le Cid,"* in which deviation from the rule is denounced. His great reputation seemed to be enhanced by the success of the first 12 cantos of his epic *La Pucelle* (1656), on which he had been at work for 20 years, but it was shattered by Gilles Boileau in his early satires, and the remaining cantos of the epic remained unprinted until 1882, when they were edited by H. Herluison. Chapelain drew up the statutes of the academy, and laid down the rules for the great grammar and dictionary to be produced.

In 1663 Chapelain was employed by Jean-Baptiste Colbert to draw up a list of men of letters with observations for use by the crown in the distribution of honours and pensions.

BIBLIOGRAPHY.—There is a very favourable estimate of Chapelain' merits as a critic in George Saintsbury's *A History of Criticism*, ii 256–261, 3 vol. (1900–04). An analysis of *La Pucelle* is given in pp 23–79 of Robert Southey's *Joan of Arc* (1796). *See* also *Les Lettres d Jean Chapelain* (edit. P. Tanuzey de Larroque, 1880–83); *Lettre inédites . . . à P. D. Huet* (1658–73, edit. L. G. Pellissier, 1894) Julien Duchesne, *Les Poèmes épiques du XVIIe siècle* (1870); the abb A. Fabre, *Les Ennemis de Chapelain* (1888), *Chapelain et nos deu premières académies* (1890); A. Muehlan, *Jean Chapelain* (1893) George Collas, *Jean Chapelain* (1912). *See* further the edition o Chapelain's critical work, *Jean Chapelain, opuscules critiques*, publishe with an introduction by Alfred C. Hunter in 1936, and the Universit of Minnesota edition of *Les Sentiments de l'Académie française su "le Cid"* (1916).

CHAPEL-EN-LE-FRITH, an old market town in Derby shire, Eng., 5¼ mi. N. of Buxton by road. Pop. (1950) 6,01c The manufacture of brake and clutch linings is important. Th site was formerly part of the royal forest (or *frith*) of the Peak The church of St. Thomas of Canterbury dates from the 13th cen tury and the Ford hall from the 15th.

CHAPEL HILL, a town of Orange county, North Carolina U.S., on a high ridge 28 mi. N.W. of Raleigh, in a dairying, tobacc and cotton-growing district. It is on federal highways 15 and 501 served by the Southern railway. Pop. (1950) 9,169. It is th seat of the University of North Carolina, which occupies a beauti ful campus of 106 ac. and owns adjoining tracts of 1,500 ac.

CHAPELLE ARDENTE, the chapel or room in which th corpse of a sovereign or other exalted personage lies in stat pending the funeral service. The name is in allusion to the many candles lighted round the catafalque. This custom is first chron icled as occurring at the obsequies of Dagobert I (602–638).

CHAPERON, originally a cap or hood (Fr. *chape*) worn b nobles and Knights of the Garter in full dress, and after the 16t century by middle-aged ladies. In the 19th century the word wa used of a married or elderly lady (*cf.* "duenna") escorting or pro tecting a young and unmarried girl in public places and in society

CHAPLAIN, originally, according to Du Cange (*Gloss. med et inf. Lat.*), the custodian of the cloak (*cappa* or *capella*) of St Martin of Tours, which was preserved as a relic by the Frenc kings, and carried with the army in wartime, when it was kept i a tent known itself as *capella* (Fr. *chapelain;* M. Lat. *capellanus*) It is also suggested that the *capella* was the tent-like canop erected by the French kings over the altar for soldiers in the field without special reference to St. Martin. However this may be, th name *capellanus* was generally applied to custodians of sacre relics preserved in royal chapels, etc.; and the office gradual extended its scope, *capellani* acquiring spiritual jurisdiction an increasing in number, so that an arch-chaplain was appointed a their head, who from the time of Charlemagne was a high prelate

and who became an important personage in the realm. In France the arch-chaplain was grand-almoner, and both in France and in the Holy Roman Empire was also high chancellor of the realm. The office was abolished in France in 1789, revived by Pius IX. in 1857, and again abolished on the fall of the Second Empire. The word chaplain now signifies a clergyman attached to the household of a sovereign or his representatives (ambassadors, judges, etc.), or of a bishop or nobleman, or private individual having a chapel in his house, to the army or navy, or to institutions (*e.g.* parliament, colleges, cemeteries, prisons). As chaplain he has no parochial duties, but in some cases a parish priest is also appointed to a chaplaincy; *e.g.* an Anglican bishop often appoints beneficed clergymen as his examining chaplains. The British sovereign has 36 "Chaplains in Ordinary," who officiate in rotation, as well as "Honorary Chaplains" and "Domestic Chaplains." There are also royal chaplains in Scotland. The Indian civil service appoints a number of chaplains of the Church of England and the Church of Scotland, who are subject to the same conditions as other civil servants. Chaplains are also appointed under the Foreign Office to embassies, consulates, etc. Workhouse chaplains are appointed by overseers and guardians on the direction of the Ministry of Health. Prison chaplains are appointed by the home secretary.

In the British army there are two kinds of chaplains, permanent and occasional. The former, described as Chaplains to the Forces, hold commissions, serving throughout the empire except in India; they number about 100, and include a Chaplain-General who ranks as a major-general, and four classes of subordinate chaplains who rank respectively as colonels, lieutenant-colonels, majors and captains. Special chaplains (Acting Chaplains for Temporary Service) may be appointed by a secretary of state. Permanent chaplains may be Church of England, Roman Catholic or Presbyterian; Wesleyans (if they prefer not to accept commissions) may be appointed Acting Chaplains. In the navy, every large ship in commission has a chaplain; at the head of the naval chaplains is the Chaplain of the Fleet. But the ecclesiastical superior of all Roman Catholic chaplains in both army and navy is the archbishop of Westminster, by decree of Propaganda (1906). In 1909 a Chaplains' Department of the Territorial Force was formed, having no denominational restriction.

In France, military and naval chaplaincies were abolished on the separation of Church and State. In the army of the United States of America the establishment of chaplains was fixed in 1904 by Congress at 57 (15 with the rank of major), 12 for the artillery corps and one each for the cavalry and infantry regiments. There is no distinction of sect. In the U.S. navy the chaplains number 24, 13 ranking as lieutenants, seven as commanders, four as captains.

The Roman Catholic Church also recognizes a class of beneficed chaplains, supported out of "pious foundations" for the specific duty of saying, or arranging for, certain masses, or taking part in certain services. These chaplains are classified as follows:—*Ecclesiastical*, if the foundation has been recognized officially as a benefice; *Lay*, if this recognition has not been obtained; *Mercenary*, if the benefaction has been entrusted to a layman to procure the desired celebration (such trustees are sometimes called "Lay Chaplains"); *Collative*, if it is provided that a bishop shall erect the foundation into a benefice.

Other classes of chaplains are:—(1) *Parochial* or *Auxiliary Chaplains*, appointed to assist a parish priest (usually by the bishop, but sometimes by the parish priest, as allowed by the Council of Trent); (2) *Chaplains of Convents*, appointed by a bishop: these must be men of mature age, should not be regulars if secular priests can be obtained, and are not generally appointed for life; (3) *Pontifical Chaplains*, some of whom (known as Private Chaplains) assist the pontiff in the celebration of Mass; others attached directly to the pope are honorary private chaplains who occasionally assist the private chaplains, private clerics of the chapel, common chaplains and supernumerary chaplains. The common chaplains were instituted by Alexander VII., and in 1907 were definitely allowed the title "Monsignore"—pertaining also to cardinals, archbishops, and bishops—by Pius X.

CHAPLIN, CHARLES SPENCER (1889-), cinema actor, was born April 16, 1889, of English parentage, and passed his childhood in London. At an early age he appeared on the music-hall stage with his father and his brother Sydney, taking small parts in vaudeville. After a short experience on the legitimate stage, he re-entered vaudeville in London as a member of the Fred Karno company. In 1910 he went to the United States as leading comedian in a Karno production, *A Night in an English Music Hall*. He attracted the attention of Joseph M. Schenck, and on the latter's suggestion he was engaged by Mack Sennett to make films with the Keystone Comedy Company at Hollywood, California. In 1918 he formed his own company, and he produced a series of films which placed him in the front rank of artists. Among the more successful of his later releases were: *A Dog's Life* (1918), *Shoulder Arms* (1918), *The Kid* (1921), *The Idle Class* (1921), *The Gold Rush* (1925), and *The Circus* (1926). In all of these he was the central figure. In 1931, he produced and acted in *City Lights*, in 1936 *Modern Times*, in 1940 *The Great Dictator* and in 1947 *Monsieur Verdoux*.

CHAPLIN, HENRY CHAPLIN, 1ST VISCOUNT (1840–1923), English statesman, son of the Rev. Henry Chaplin, of Blankney, Lincolnshire, was born Dec. 22, 1840, and died May 29, 1923. He was educated at Harrow and Christ Church, Oxford. Entering parliament in 1868, he sat as Conservative member, first for Mid-Lincolnshire (1868–1906), and then for Wimbledon. As the typical English country gentleman, the "Squire of Blankney" was one of the leaders of the agricultural interest. He was chancellor of the duchy of Lancaster (1885–86) and president of the new Board of Agriculture (1889–92); as president of the Local Government Board (1895–1900) he was responsible for the Agricultural Rates Act of 1896, and he was a member of Mr. Chamberlain's Tariff Commission. During the Coalition government of 1915, Chaplin was the leader of the nominal opposition until his elevation to the peerage in 1916.

See E. Stewart, *Henry Chaplin* (1926).

CHAPMAN, FRANK MICHLER (1864–1945), American ornithologist, born at Englewood, N.J., June 12, 1864, had no formal education beyond academy. He joined the staff of the American Museum of Natural History, New York city, as assistant in 1887, served as assistant curator (1888–1901) and associate curator (1901–08) of ornithology and mammalogy, and as curator of ornithology (1908–42) until his retirement. He died in New York city on Nov. 15, 1945. He originated the habitat bird groups and seasonal bird exhibits; and, beginning in 1887, travelled widely, collecting and photographing the birds of temperate and tropical America. He did pioneer work to popularize bird study, publishing his widely used *Handbook of Birds of Eastern North America* (1895), *The Warblers of North America* (1907), and a dozen other popular books. His technical papers covered life histories, geographical distribution, and systematic relationships of American birds, after 1911 dealing largely with the origin of Andean bird life and resulting in volumes on *The Distribution of Bird Life in Colombia* (1917), *Birds of the Urubamba Valley, Peru* (1921), and *The Distribution of Bird-Life in Ecuador* (1926). His field adventures are well presented in his *Camps and Cruises of an Ornithologist* (1908) and *Autobiography of a Bird-Lover* (1933). He was founder and editor (1898–35) of *Bird-Lore* magazine, president of the American Ornithologists union (1911–14), and vice-president of the Explorers club (1910–18). He was awarded the first Linnean medal (1912), the first Elliot medal (1918) of the National Academy of Sciences, the Roosevelt medal (1928) and the Burroughs medal (1929). Brown university, Providence, R.I., awarded him the Sc.D. degree in 1913. (G. F. Ss.)

CHAPMAN, GEORGE (1559–1634), English poet and dramatist, translator of Homer, was born near Hitchin. There is no record of his university career, though Anthony Wood (*Athen. Oxon.* ii. 575) claims that he spent some time in Oxford. He had become a play-writer in London, and had published some poems when he appeared in Henslowe's *Diary* on Feb. 12, 1596, as the author of the *Blind Beggar of Alexandria*. Thenceforward his name repeatedly appears in connection with payments for various plays until 1599, after which date he appears to have

written masques for the Children of the Chapel (afterwards of the Revels) in the intervals of working on the translation of Homer. In 1508 he had completed Marlowe's poem, *Hero and Leander*. Apparently he was imprisoned for a short time for his share in the play *Eastward Ho*, which gave offence to James I by certain quips against the Scots. He was encouraged in his translation of Homer by Prince Henry, to whom he was server in ordinary, but on the prince's death in 1612 Chapman lost his appointment and the promise of a life pension made by the prince was not fulfilled. He found a new patron in Robert Carr, earl of Somerset, to whom the two folio volumes *The Whole Works of Homer, Prince of Poets, in his Iliads and Odysses* (1615) are dedicated. *The Crowne of all Homer's Workes, Batrachomyomachia, or the Battaile of Frogs and Mise. His Hymns and Epigrams* appeared in 1624. The poet died on May 12, 1634.

Chapman enjoyed the friendship and admiration of his great contemporaries. John Webster in the preface to his *White Devil* praised his "full and heightened style," and Ben Jonson told Drummond of Hawthornden that Fletcher and Chapman "were loved of him." But the good relations with Jonson were apparently interrupted later. It was suggested by William Minto, who has been followed by later writers, that Chapman was the "rival poet" of Shakespeare's sonnets. Sir E. K. Chambers, however, thinks that the assumption would be more plausible if any relation between the earl of Southampton and Chapman, earlier than a stray dedication shared with others in 1609, could be established.

Chapman's *Homer* gives him a high place in English literature. Swinburne, in the criticism contributed to an earlier edition of the *Encyclopædia Britannica*, gave an admirable and considered judgment of the work. "The objections," he said, "which a just and adequate judgment may bring against Chapman's master-work, his translation of Homer, may be summed up in three epithets: it is romantic, laborious, Elizabethan. The qualities implied by these epithets are the reverse of those which should distinguish a translator of Homer; but setting this apart, and considering the poems as in the main original works, the superstructure of a romantic poet on the submerged foundations of Greek verse, no praise can be too warm or high for the power, the freshness, the indefatigable strength and inextinguishable fire which animate this exalted work."

On the great qualities of his tragedies and comedies Swinburne wrote: "The most notable examples of his tragic work are comprised in the series of plays taken, and adapted sometimes with singular licence, from the records of such parts of French history as lie between the reign of Francis I. and the reign of Henry IV., ranging in date of subject from the trial and death of Admiral Chabot to the treason and execution of Marshal Biron. The two plays bearing as epigraph the name of that famous soldier and conspirator are a storehouse of lofty thought and splendid verse, with scarcely a flash or sparkle of dramatic action. The one play of Chapman's whose popularity on the stage survived the Restoration is *Bussy d'Ambois* (d'Amboise)—a tragedy not lacking in violence of action or emotion, and abounding even more in sweet and sublime interludes than in crabbed and bombastic passages. His rarest jewels of thought and verse detachable from the context lie embedded in the tragedy of *Caesar and Pompey*, whence the finest of them were first extracted by the unerring and unequalled critical genius of Charles Lamb. In most of his tragedies the lofty and labouring spirit of Chapman may be said rather to shine fitfully through parts than steadily to pervade the whole; they show nobly altogether as they stand, but even better by help of excerpts and selections. But the excellence of his best comedies can only be appreciated by a student who reads them fairly and fearlessly through, and, having made some small deductions on the score of occasional pedantry and occasional indecency, finds in *All Fools, Monsieur d'Olive, The Gentleman Usher*, and *The Widow's Tears* a wealth and vigour of humorous invention, a tender and earnest grace of romantic poetry, which may atone alike for these passing blemishes and for the lack of such clear-cut perfection of character and such dramatic progression of interest as we find only in the yet higher poets of the English heroic age."

The list of the principal plays of George Chapman is as follows: *The Blinde Begger of Alexandria* . . . (acted 1596, printed 1598), a popular comedy; *An Humerous dayes Myrth* (May 1597; printed 1599); *Al Fooles, A Comedy* (1599, if it may be taken as identical with a play entered by Henslowe as "The World runs on wheels," printed 1605); *The Gentleman Usher* (*c.* 1601, pr. 1606), a comedy; *Monsieur d'Olive* (1604, pr. 1606), one of his most amusing and successful comedies; *Eastward Ho* (1605), written in conjunction with Ben Jonson and John Marston, an excellent comedy of city life; *Bussy d'Ambois, A Tragedie* (1604, pr. 1607, 1608, 1616, 1641, etc.), the scene of which is laid in the court of Henry III.; *The Revenge of Bussy d'Ambois, a Tragedie* (pr. 1613, but probably written much earlier); *The Conspiracie, And Tragedie of Charles Duke of Byron, Marshall of France . . . in two plays* (1608; pr. 1608 and 1625), severely cut after its first performance, which provoked a lively protest from the French ambassador; *May-Day, A witty Comedie* (pr. 1611, but probably acted as early as 1601); *The Widdowes Teares, A Comedie* (pr. 1612; produced perhaps as early as 1605); *Caesar and Pompey* (pr. 1631), written, says Chapman in the dedication, "long since," but never staged.

In *The Tragedie of Chabot Admirall of France* (*c.* 1613; pr. 1639) he collaborated with James Shirley, and in *Eastward Ho* (1605, pr. 1605), with Jonson and Marston. *The memorable Masque of the two Honourable Houses or Inns of Court*, was performed at court in 1613 in honour of the marriage of the Princess Elizabeth.

The standard edition of Chapman is the *Works*, edited by R. H. Shepherd (1874–75), the third volume of which contains an "Essay on the Poetical and Dramatic Works of George Chapman," by Swinburne, printed separately in 1875. The selection of his plays (1895) for the Mermaid Series is edited by W. L. Phelps. The edition by T. M. Parrott (1910–14) includes *Alphonsus, Emperor of Germany*, and other plays sometimes attributed to Chapman. For the sources of the plays *see* Emil Koeppel, "Quellen Studien zu den Dramen George Chapman's, Philip Massinger's und John Ford's," in *Quellen und Forschungen zur Sprach und Kulturgeschichte* (vol. 82, Strassburg, 1897). The suggestion of W. Minto (see *Characteristics of the English Poets*, 1885) that Chapman was the "rival poet" of Shakespeare's sonnets is amplified in A. Acheson's *Shakespeare and the Rival Poet* (1903). For the relations between Shakespeare and Chapman, *see* also J. M. Robertson, *Shakespeare and Chapman* (1917).

For other criticisms of his translation of Homer *see* Matthew Arnold, *Lectures on translating Homer* (1861), and Dr. A. Lohff, *George Chapman's Ilias-Übersetzung* (1903).

CHAPMAN, JOHN ("Johnny Appleseed") (1774–1845), American frontier nurseryman and folk character, was born in Leominster, Mass., Sept. 26, 1774. Little is known of him until he appeared in western Pennsylvania shortly before 1800. According to tradition, he had planted by 1801 a chain of seedling apple nurseries in advance of the settlements from the Allegheny to central Ohio. He spent about 25 years in north-central Ohio. Here the "Johnny Appleseed" stories largely originated, springing not only from his business, but from his eccentricities of manners and dress, Swedenborgian religious views, extreme kindness to wild animals, great generosity and unusual exploits of courage and endurance. By 1828 his nurserying reached northwestern Ohio and Indiana.

From 1834 Chapman operated around Fort Wayne, Ind., where he died in March 1845.

The folktales portray him on a spiritual mission preparing the wilderness for the westward movement. He has become the patron saint of American orcharding, floriculture and conservation. Late extension of the early oral tradition has been largely literary—stimulated notably by Henry Howe's *Historical Collections of Ohio* (1847, 1889), an article by W. D. Haley in *Harper's* Nov. 1871, and later imaginative treatments such as those by Eleanor Atkinson, Vachel Lindsay, Newell Dwight Hillis and Walt Disney.

Wheeler, "John Chapman's Line of Descent from Edward Chapman of Ipswich," *Ohio Archaelogical and Historical Quarterly* (Jan. 1939). (RT. P.)

CHAPMAN, one who buys or sells, a trader or dealer, especially an itinerant pedlar. The word "chap," now a slang term, meant originally a customer. The word chapman is from Mid. Eng. *cheap*, to barter, from which we get the name of the famous London thoroughfare "Cheapside."

CHAPONE, HESTER (1727–1801), English essayist, daughter of Thomas Mulso, a country gentleman, was born at Twywell, Northamptonshire, on Oct. 27, 1727. At the age of

nine she wrote a romance entitled *The Loves of Amoret and Melissa*. While on a visit to Canterbury she met the learned Mrs. Elizabeth Carter, and then became one of the little court of women who gathered at North End, Fulham, around Samuel Richardson, and in Miss Susannah Highmore's sketch of the novelist reading *Sir Charles Grandison* to his friends Miss Mulso is the central figure. In 1760 Miss Mulso, with her father's reluctant consent, married the attorney, John Chapone, who had been befriended by Richardson. Her husband died within a year of her marriage. Her best known work, *Letters on the Improvement of the Mind* (1772) brought her numerous requests from distinguished persons to undertake the education of their children. She died on Dec. 25, 1801.

See *The Posthumous Works of Mrs. Chapone, containing her correspondence with Mr. Richardson; a series of letters to Mrs. Elizabeth Carter . . . together with an account of her life and character drawn up by her own family*, 4 vol. (1807).

CHAPPE, CLAUDE (1763–1805), French engineer, was born at Brûlon (Sarthe) in 1763. With his brother, Ignace (1760–1829), he was the inventor of an optical telegraph widely used in France until it was superseded by the electric telegraph. His device consisted of an upright post, on the top of which was fastened a transverse bar, while at the ends of the latter two smaller arms moved on pivots. The position of these bars represented words or letters; and by means of machines placed at such intervals that each was distinctly visible from the next, messages could be conveyed through 50 leagues in a quarter of an hour. The machine was adopted by the legislative assembly in 1792, and in the following year Chappe was appointed *ingénieur-télégraphe;* but the originality of his invention was so much questioned that he was seized with melancholia and (it is said) committed suicide at Paris on Jan. 23, 1805.

CHAPPELL, WILLIAM (1809–1888), English writer on music, a member of the London musical firm of Chappell and Co., was born on Nov. 20, 1809, eldest son of Samuel Chappell (d. 1834), who founded the business. William Chappell deserves remembrance for having started the Musical Antiquarian society in 1840 and for his *Popular Music of the Olden Time* (1855–59)—an expansion of a collection of "national English airs" made by him in 1838–40.

The modern revival of interest in English folk songs owed much to this work, which was later re-edited by H. E. Wooldridge (1893). William's brother, Thomas Patey Chappell (d. 1902), introduced in 1859 the Monday and Saturday Popular concerts at St. James's hall, which were successfully managed by a younger brother, S. Arthur Chappell, till they came to an end toward the close of the 19th century.

CHAPTER HOUSE, the chamber in which the chapter or heads of the monastic bodies (*see* ABBEY; CATHEDRAL) assemble to transact business. They are of various forms; some are oblong apartments, as Canterbury, Exeter, Chester, Gloucester, etc.; some octagonal, as Salisbury, Westminster, Wells, York, etc. That at Worcester is circular; most are vaulted internally and polygonal externally, and some, as Salisbury, Wells, Lincoln, Worcester, etc., depend on a single slight vaulting shaft for the support of the massive vaulting. They are often provided with a vestibule, as at Westminster, Lincoln and Salisbury and are almost exclusively English. On the continent of Europe the chapter house is universally rectangular and frequently of great size and dignity.

In the United States the word chapter house refers almost invariably to the campus meeting or residence halls of the members of the collegiate Greek-letter societies—fraternities or sororities with names chosen from various combinations of the Greek alphabet, as Delta Theta Psi, Sigma Alpha, etc.

CHAPU, HENRI (1833–1891), French sculptor and medallist, born in Le Mée (Seine et Marne) on Sept. 29, 1833. He studied at the École des Beaux-Arts under Pradier and Duret and, having gained the Prix-de-Rome in 1855, spent five years in Rome. He was famous as a portrait medallist, and he executed many portrait busts and monuments; his statuary representing allegorical and mythological figures is sincere in feeling and poetical in conception.

His first success was attained by a figure of "Mercury" (1861, Luxembourg museum, Paris); then followed "The Sower" (1865); the "Nymph Clythia" (1866, Dijon museum). His fame was established by his statue of "Jeanne d'Arc" (1870, Luxembourg museum), representing her as a simple peasant kneeling in prayer. In 1872 Chapu undertook the monument to Henri Regnault with the fine figure of "Jeunesse" in the courtyard of the École des Beaux-Arts. In 1877 he sculptured the tomb of the Contesse Agoult (Daniel Stern) at Père Lachaise, and in 1887 he completed the monument to the archbishop Dupanloup. Among his portrait work may be mentioned Leon Bonnat (1864); Alexandre Dumas (1876); the bronze of J. E. Schneiders (1878) at Le Creuzot; the monument to the Galignani brothers (1888), representing them in modern costume, which was then an innovation and excited much comment, and the bust of Alexandra, Princess of Wales. The monument to Flaubert, with an allegorical figure of "Truth," is his last important work. Chapu died in Paris on April 21, 1891. The museums of Rouen and Bayonne contain a number of his drawings.

See O. Fidère, *Chapu, sa vie et son oeuvre* (1894).

CHAPU, a port of China on the north shore of Hangchow bay (30° 39′ N., 121° 6′ E.). It is built on a series of low hills and was long an outport of Hangchow. Chapu was the only harbour at Hangchow bay near Shanghai (50 mi.). At Chapu the Japanese succeeded in landing, in Nov. 1937, on the flank of the Chinese armies retreating from Shanghai.

CHAPULTEPEC, ancient seat of the Montezumas, situated in the west quarter of the city of Mexico.

On its rocky heights stands the summer palace of the president of the republic, in which is housed also the National Military school. At the base of this rising ground which commands the surrounding country is located a famous grove of cypresses estimated to be some thousand years old. Upon this whole critical position was fought the last actual battle of the war between Mexico and the United States (1846–48). Maj. Gen. Winfield Scott after the disaster of El Molino del Rey found that he had available about 7,000 badly shaken United States troops, far from their base and in the heart of a hostile country. Opposing him General Antonio Lopez de Santa Anna, the president of the republic, controlled at least twice that number. The natural and artificial strength of the palace, its proximity to the U.S. goal and its meaning relative to governmental power made its possession by the contending forces of the greatest moment. After several days of reconnaissance, feints and preparations, Scott decided that this stronghold between him and the capital must be taken.

On Sept. 12, 1847, an all-day bombardment of the buildings, surrounding forts and redoubts convinced him of the necessity of an assault. During the following night both the U.S. and Mexican batteries and positions were strengthened and Scott's plans for an attack in front and reverse were crystallized. Maj. Gen. J. A. Quitman's troops were directed to advance to the rear of the palace by way of the Tacubaya road, whereas Maj. Gen. G. J. Pillow's division was given the task of striking the front by way of El Molino del Rey and the cypress grove. From early dawn on Sept. 13 until 8 A.M.—about two hours and a half—the U.S. guns hurled solid shot, grape, canister and shells at the barriers of stone and mortar. At the end of that time the infantry went forward to the assault, the main blow being delivered by regular troops upon the Mexican points of vantage in the cypress grove. Lieut. "Stonewall" Jackson, later of Civil War fame, handled on his own initiative a section of John B. Magruder's field battery in such a manner as to cut off the northern retreat of the Mexican fugitives. The major portion of Scott's forces went forward doggedly under severe fire. Officers on both sides became casualties to a disproportionate degree. When the United States troops finally reached the ditch they found there no ladders with which to scale the parapets. Although Brig. Gen. P. F. Smith gallantly led a turning movement toward the rear of the palace, he was met by such a galling fire that his losses, including the wounded Lieut. James Longstreet, were sufficient to stop him.

The suspense and curtailment of enthusiasm among Scott's troops as they crouched behind any available cover, while waiting

for the implements that would enable them to go over the top of the barrier, lent serious apprehensions as to the success of the U.S. effort. When, after about 20 min., the ladders arrived, the previous restiveness reacted upon the men in the form of ardour to proceed. They swarmed over the parapets with such impetus that in a very few minutes of sharp hand-to-hand fighting Chapultepec was in their hands. Since its capture was but a means to an end, and the exploitation of the success involved the seizure of the city of Mexico itself, it was necessary to move onward immediately. Quitman set out over the Belen causeway toward the capital. After overwhelming a field redan in his front he came upon decided opposition at the gate which was protected by a formidable citadel beyond. Quitman's ammunition having been exhausted and all his staff officers having been killed or wounded, his position was not fortunate.

To check Mexican reinforcements, Scott sent Brigadier General Worth's brigade, together with some smaller units, along the Verónica causeway. Finding his advance likewise blocked by heavy fire, Worth sent Col. John Garland's force through the fields to outflank the San Cosme gate which lay about a mile north of Quitman's troops. By crawling through mud, forcing their way through houses and using such cover as was available, in small bodies they reached the rear of the position. During this procedure, Lieut. U. S. Grant had a mountain howitzer dragged through the mud and mounted upon the roof of a building. About six o'clock in the evening Worth forced an entrance into the city proper, and shortly activities ceased for the night. Though the capital was not yet under U.S. control, General Santa Anna chose to retire with his forces to Guadalupe Hidalgo. Next morning when Scott was ready to renew hostilities, the city of Mexico was unexpectedly surrendered.

CHAR, the name given to fishes of the genus *Salvelinus,* which differs from *Salmo* (salmon and trout) in having the vomerine teeth present only on the head of the bone, which is raised and has a boat-shaped depression behind it. *Salvelinus alpinus* of the Arctic ocean is a marine fish that enters rivers to breed and may form fresh-water colonies, especially in lakes. It is represented by many isolated colonies in lakes that it entered in glacial times, far to the south of its present range in the sea, in Scandinavia and the Alps, in Scotland, Ireland and the Lake District of England and in North America. Many of these lacustrine forms differ considerably from the northern migratory char and have been described as distinct species; they are more or less similar to trout but have smaller scales and are generally beautifully coloured—bluish or olive above often with bright orange spots on the sides; the belly varies from pink to scarlet, the coloration being most intense in the breeding males. The migratory fish are silvery, with the spots inconspicuous. *Salvelinus fontinalis,* the brook trout of eastern North America, is mainly a river fish, distinguished by the blackish mottling of the back and the dorsal and caudal fins; sea-run individuals (the Canadian "salmon trout") are plain silvery. *Cristivomer namaycush,* the Great Lake trout of North America, is a grayish fish with dark markings on the dorsal and caudal fins; it is distinguished from other char by the widely forked caudal fin; it reaches a weight of 100 lb. (C. T. R.)

CHARABANC, a large form of wagonette-like vehicle for passengers, with benched seats arranged in rows, looking forward, commonly used for large parties, as public conveyances or for excursions. The word is French for benched carriage; in the English motor trade the term "motor coach" is preferred.

CHARACTER. To ask what character is, reveals the confusion of ordinary thought about it. Instincts, habits, impulses, desires, emotions, sentiments all belong to it. But what relation do they bear to one another? What is the part of character that has to be controlled and what is its controlling part? Whence come those things that are called "principles" of conduct, and "ideals," and the multitude of "qualities of character"—courage, steadfastness, sincerity, tolerance, generosity, patience and honesty and their opposites? We do not know. The first general problem of the psychology of character is therefore to transform the chaos of the ordinary conception of it into one in which the parts of character are seen to bear a clear and intelligible relation to the whole. There are certain common but useful antitheses, "character and intelligence"; "character and circumstances"; "character and conduct." Conduct is the expression of character; only actions that are in some degree under voluntary control are included in conduct. Reflex actions are not included in conduct; instinctive actions are. Character is the driving force; intelligence guides it to its destination; together they sum up the human mind and are inseparable in it.

Stages of Character.—These may be classed under three heads, which roughly correspond to three levels of mental development: (1) the instinctive; (2) the emotional; (3) the level of sentiment; and again roughly these three are represented in (1) the life of the animal; (2) the life of the child and (3) the life of the adult human being. The first is the most perfect in organization; but also the most rigid, in which intelligence has the least formative influence. The second is the most helpless and marks the transition from a lower to a higher form of organization, for which the guidance of the adult mind is indispensable. The third is the most plastic and comprehensive; but its organization is never completed. In it reflection, reason and self-control have their full opportunities; yet it is the region of folly and error with which we can hardly charge the animals; of mistaken valuations followed by disillusions; of progress and decadence; of constancy and infidelity. It has never been understood.

The Human Instincts.—Animal instincts are inherited dispositions having specific patterns of behaviour for the attainment of their ends. An impulse felt in consciousness precedes their operation; attention accompanies it and serves to adapt the pattern of behaviour to the actual situation. Human instincts have lost these patterns except in the case of simple instincts, as sucking, shrinking and clinging; in others the child must learn by experience to acquire new means to replace the old. The end for an animal is perceived—a hole or cover; the end for man may be conceived—a secret thought. In this sense, as instinctive impulses defined by their ends, we can enumerate the most important human instincts. They are flight and pursuit, concealment and display, domination and submission, attraction and repulsion, destruction and construction, crying for protection and giving protection, curiosity and search and the food and sex instincts. The ends are only proximate ones, assumed to have been selected first for their biological utility; but in man they are also indispensable to the ends which he invents—wealth, power, fame, well-being, happiness, perfection.

The instincts sometimes act independently of emotion, finding in their own impulses when unchecked the force to attain their ends; but (1) when their impulses are obstructed they tend to arouse anger or fear; (2) when they attain their ends, joy or satisfaction; (3) when they fail completely, sorrow or despair. The emotions never act independently of instincts and tend to organize in their systems all that subserve their ends. Hence, we find concealment not only in fear, but in the anger of revenge; in shame; in envy; in sorrow; in the joy of children's games. This seems to be the relation between instincts and emotions.

Difference Between Instinct and Emotion.—An instinct advancing to its end unchecked does not need to arouse emotion. In itself it is unlike emotion; it is most like habit. Both instinct and habit are orderly and stable, showing so little variability in action that we forecast the course of it. Emotion unrestrained is unstable and disorderly; its actions often surprise us. We follow our strong habits often without recognizing them; they are calm and unobtrusive; we can not help recognizing our strong emotions. Hence it is, when emotion and instinct are conjoined, the second as it comes into operation tends to calm the first. It is the moments before action, we remark, that are so tense. For the force which emotion brings is for the needs of a certain situation. It should not therefore persist for long; and if it does, it tends to become pathological, as we see in the case of our morbid fears.

Besides these differences between instincts and emotions there are those based on the nature of their systems. Emotion is potentially more complex. Concealment is only one of many instincts organized in fear which may choose this instinct or any other better adapted to the actual situation: flight, shrinking or clutching or shrieks for protection. From the time of Bain it has been recognized that strong emotion is accompanied by a diffused nervous disturbance, and this may render emotion more adaptable to a changing situation; whereas when an instinct is unchecked, and following out the normal course of its behaviour, the nervous discharge tends to be restricted to those channels which sustain this behaviour. Here the intervention of emotion would be not only superfluous but harmful. The value of emotion lies in these two points of difference from instinct: (1) the force which it brings to deal with a given situation and (2) its potentially more complex and adaptable system. It is indispensable to the sentiments, and without it there could neither be love nor hate. All great changes of character are initiated by emotion.

The Stage of the Sentiments.—That which has to exercise control must have a wider outlook than that which is to be controlled; but unless it moves us its warnings are ineffectual. It must move us by some other influence than emotion. Self-control comes from a higher system than emotion and one that by its comprehensiveness more adequately represents the self. Love and hate, the chief sentiments, have this comprehensiveness. They are that governing part of character to which we have referred; and all the part which has to be governed is beneath them, under their authority. Love obtains its great organizing desires directed to its unchanging ends of union, happiness and well-being of the loved object, reciprocity of love and the desire to be happy in the love of the object. But in hate these ends are reversed: not preservation and union, but destruction and separation; not happiness and well-being, but misery and the worst possible state of the object, and yet withal, the desire to be happy in the separation, misery and destruction of the object.

In these great desires love and hate find the principles of their self-control—not in their emotions.

Repression.—Repression is an extreme form of the self-control of sentiments. For if some of our emotions have to be regulated as being either too strong or too weak, others which are judged to be harmful in view of their ends have to be repressed. Such repression of things within the mind corresponds most nearly to "destruction" of things without us. We would destroy some things in our character if we could; but we can only repress them, which means to exclude them from consciousness and prevent as far as possible their return to it.

Conscience.—There is another sentiment distinct from both love and hate, which, like them, often undergoes repressions. The uniqueness of conscience makes it difficult to interpret, for there is a particular conscience belonging to all love of which its ideals are a part. This is partial to the loved object. It is the repository of that part of the moral beliefs of the community in which the individual has been instructed and which he has adopted through authority and suggestion. It is therefore apt to differ from one person to another. But when it is a living force of character, it grows with a man's experience of life and through the illusions and disappointments of love. These impress certain ideals and duties upon his mind differently from hearsay, however often repeated. They become the most vital part of his conscience, being there freed from the partiality to which love at first confined them. And as the ideals of love are much the same in its different varieties, the most general and important duties come to be impressed, sooner or later, on most men.

Thus is shown in merest outline how the parts of character are related to one another and the whole—how the instincts, habits, emotions and desires function in the sentiments of man, and there represent the unity of his character. Yet how incompletely they represent it. The potentials of his character transcend for better and worse everything that he has drawn from them to build up his actual loves and hates, and remain a perpetual enigma to him.

The word is also applied to symbols of notation; letters of the alphabet, and, more particularly to ideographs; in such phrases as "the characters of the Chinese language number nearly 50,000." By extension of the philosophical meaning a "character" has almost become synonymous with "reputation." Still further development of this idea is found in the description of a person as "a character" ("an odd or eccentric person").

BIBLIOGRAPHY.—A. Bain, *The Study of Character* (1861); A. F. Shand, *Foundations of Character* (1914); A. A. Robaek, *The Psychology of Character* (1927); Theophrastus' *Characters*, contains the oldest extant sketches of types of character. (A. F. S.)

CHARADE, a kind of riddle, probably invented in France during the 18th century, in which a word of two or more syllables is divined by guessing and combining into one word (the answer) the different syllables, each of which is described, as an independent word, by the giver of the charade. Charades may be either in prose or in verse. Of poetic charades those by W. Mackworth Praed are well known and excellent examples, while the following is a good specimen in prose. "My *first* is company; my *second* shuns company; my *third* collects company; and my *whole* amuses company." The solution is *Co-nun-drum*. The most popular form of this amusement is the acted charade, in which the meaning of the different syllables is acted out on the stage, the audience being left to guess each syllable and thus, combining the meaning of all the syllables, the whole word. A brilliant description of the acted charade is given in Thackeray's *Vanity Fair*.

In many circles of the London "intelligentsia" the charade became, by 1900, such a hobby that elaborate presentations were made, planned weeks in advance and with expensive or hard to acquire costumes and properties comparable to those used in amateur theatricals. Such elaborate charades continued to be produced in the 20th century, though simplification induced by World War I became the custom.

In the United States the charade in somewhat different form was resurgent in the 1930s and 1940s. It was called "The Game." Whatever group assembled was divided into two teams. Each team designated one member of the opposing team to personify a quotation, a person living or dead, a phrase or an idea, in such manner that his teammates might guess the subject. The designated actor was not permitted to use his voice in any way or to indicate any inanimate object in the room for the guidance of his teammates. The object of the actor was to assist his teammates in guessing the subject in the shortest possible time. A timekeeper determined the team which had arrived at the proper answer in the shorter time and thus had won the contest.

CHARADRIIDAE: *see* LAPWING; PLOVER; TURNSTONE.

CHARADRIIFORMES, an order of birds, most members of which are shore birds, gulls and auks. The young are active and down-clad at hatching.

(*See* AUKS; AVOCET; CURLEW; GULL; ORNITHOLOGY; PHALAROPE; PLOVER; SANDPIPER; SHEATHBILL; SNIPE; TERN; WOODCOCK.)

CHARCOAL. Charcoal is the residue obtained when a carbonaceous material of animal or vegetable origin is partially burned or heated in the absence of air. It is essentially an impure form of carbon (*q.v.*) produced by the unit process of pyrolysis or decomposition by heat, often called "destructive distillation" when, as in this case, the material is decomposed into volatile and nonvolatile fractions. Coke (*q.v.*) is manufactured by the application of a similar process to bituminous coal and may be regarded as a special form of charcoal.

Various charcoals are given names which identify them with the materials from which they are derived: wood charcoal, blood charcoal, etc. Bone charcoal contains only about 12% carbon and consists principally of calcium phosphate and carbonate.

Wood Charcoal.—This material was produced for many centuries by stacking wood into heaps which were partially covered with earth to limit the access of air; the heaps were fired and the charcoal recovered but all by-products were wasted.

This process has been almost completely replaced by those using by-product ovens. In the older of these, cordwood is loaded into large steel buggies which run on standard rails. They are rolled

into ovens heated by the combustion of coal, natural gas or the gas and tar formed during the carbonization. In the newer Stafford process dry wood in the form of relatively small pieces preheated to 300° F. is charged continuously into large cylindrical retorts. Once started, the process maintains itself by the heat liberated in the decomposition reactions.

The vapours from either of these processes are cooled to condense tar and pyroligneous liquor which form separate layers. The aqueous layer is redistilled to remove soluble tar. In the older recovery processes acetic acid was obtained by neutralizing the pyroligneous acid with lime, evaporating to dryness and liberating the acetic acid from its calcium salt by means of sulphuric acid. In 1945 this process was used in only a few small plants, the others having adopted more economical operations depending upon rectification and selective solvent extraction.

The products obtained from the distillation of hardwood are given by R. S. McBride as follows in per cent by weight: charcoal 25.2, methanol 1.9, acetic acid 2.0, tar and oil 5.0, gas 18.3, water, etc., 46.7. The gas from the process consists mainly of carbon dioxide 53%, carbon monoxide 27% and methane 15%.

After the production of acetone by fermentation (1915) and later from propylene, its manufacture by destructive distillation of calcium acetate was abandoned. The commercial synthesis of methanol from carbon monoxide and hydrogen and the advent of cheap acetic acid made from acetylene or ethyl alcohol caused the prices of the principal by-products of the charcoal industry to decrease considerably. As a result, in 1940 only 9% of the methanol was made by wood distillation and the large additional demand for methanol from which to produce the formaldehyde required for plastics and explosives needed in World War II was met by still greater expansion of the synthetic methanol industry.

Wood distillation may be expected to continue on a stable basis but by mid-century and after it supplied a diminishing fraction of the total market for all of its principal by-products with the exception of wood tar. The demand for charcoal is thus the factor which determines the magnitude of the wood distillation industry. In fact, interest has revived in charcoal processes in which the by-products are burned because of their low value. The chief use for charcoal is as a blast-furnace fuel although coke is much more commonly employed. Where natural or artificial gas or cheap electricity is not readily available charcoal is employed as a household cooking fuel, its clean flame and great ability to radiate heat recommending it particularly for broiling. Charcoal is employed for miscellaneous metallurgical purposes such as case hardening (*q.v.*), in the manufacture of black powder and as a starting material for chemical synthesis. Carbon disulphide, important in the production of carbon tetrachloride (fire-extinguisher fluid and dry-cleaning agent) and of rayon and rubber accelerators, is made by the action of sulphur on charcoal. Sodium cyanide, important in the metallurgy of gold and silver, as a poison and in the manufacture of plastics, is made by passing ammonia over a mixture of sodium and charcoal.

Activated Charcoal.—The ability of charcoal to deodorize air and decolorize solutions has long been known. These effects occur through the phenomenon of adsorption (*q.v.*) by which charcoal, in common with other solids of large internal area, attracts and holds on the surface of its pores various materials which while there sometimes undergo chemical change. Since charcoal adsorbs oxygen from the air, organic materials simultaneously adsorbed may be oxidized while held on the charcoal surface. Polymerization and hydrolysis frequently occur. Before 1900, R. von Ostrejko made the important discovery that the adsorptive power of charcoal may be strongly enhanced by partial oxidation at a bright red temperature in a current of steam or carbon dioxide. A similar effect is obtained by the action of oxygen (air) at much lower temperatures (300–450° C.) but this reaction is exothermic and thus harder to control. The subjection of charcoal to the action of a limited air supply in the temperature range 800–1,000° C. results in excellent activation; the chemical attack on the charcoal in this case is primarily by carbon dioxide formed in the reaction between carbon monoxide and inwardly diffusing oxygen. The product of such processes is called activated charcoal or active carbon.

Another method of obtaining active charcoal is to carbonize organic material by heating it in the presence of certain solutions such as aqueous zinc chloride or phosphoric acid which exert a dissolving action upon the organic matter and a catalytic effect upon its pyrolysis. A higher yield of charcoal is obtained than in ordinary destructive distillation and the original cell structure, which is reproduced in ordinary charcoal with the utmost fidelity, may disappear completely, the resulting product having a black, glassy fracture. After the impregnated charcoal has cooled, it is extracted with water and acid to remove foreign materials and then dried.

During World War I, N. K. Chaney discovered that lignite, bituminous or anthracite coal may serve as an economical source of excellent activated charcoal if it is carefully carbonized and subjected to steam activation. Chlorinated coal behaves particularly well but requires a binder such as wood tar followed by recarbonization to form pellets which are mechanically strong.

Active carbon is manufactured for three principal purposes: (1) gas masks; (2) decolorization; and (3) water purification. The advent of chemical warfare in World War I sharply emphasized the value of activated carbon in a respirator or gas mask. Removal of toxic vapours must be remarkably complete since a concentration of a few parts per million of such gases as phosgene may result fatally. Of all materials tried only active charcoal was satisfactory and by the end of the war the soldiers of all belligerent countries were wearing respirators containing it. The Allies employed partial oxidation processes and nut shells and hardwood were the principal sources of the charcoals employed Germany used a zinc-chloride process operated on pine wood.

After World War I active carbons were employed for the removal of gasoline vapours from natural gas and for solvent recovery in connection with such processes as the manufacture of artificial leather, pyroxylin window shades and metal lacquering where large quantities of relatively expensive solvents are evaporated. By 1930 the charcoal gasoline recovery process was almost entirely obsolete but installations employing active carbon were later used increasingly for solvent recovery where their slightly greater initial and operating costs were compensated for by their high efficiency, particularly where the material recovered was expensive or occurred at low concentration.

Bone charcoal towers were first used for decolorizing sugar solutions in 1815. Vegetable decolorizing carbons threatened to displace them after their commercial introduction around 1910 because only one-thirtieth the quantity of material is required and there is a consequent saving in time, fuel, wash water, building space and investment in equipment. Plants employing activated carbon can operate efficiently on a much smaller scale than those using bone char and hence are often built adjacent to the raw sugar mills to produce "plantation white" sugar. Sugar refineries with bone char towers already installed, however, have little incentive to change over to vegetable decolorizing carbons.

Where highly acidic solutions are decolorized, bone black is unsuitable because of its high ash content. Here decolorizing carbons replaced older forms of charcoal.

A still later application of active carbon is in the elimination of the objectionable odour of city water which contains chlorophenols formed by the action of chlorine (introduced to kill bacteria) upon traces of phenols present in the water. Relatively small quantities of activated carbon, introduced as a powder and removed by filtration or present as a bed of granular material through which the water trickles, will render the water palatable. The same may be said for colours and odours produced by algae growing in reservoirs.

CHARCOT, JEAN BAPTISTE ETIENNE AUGUSTE (1867–1936), the son of the French physician Jean M. Charcot (*q.v.*), was educated as a physician but became best known as an

explorer. Born at Neuilly-sur-Seine in 1867, Jean Baptiste Charcot who studied at the École Alsacienne, was an intern at the Hospital of Paris from 1890 to 1894 and was also connected with the Pasteur institute, 1890–93. He was chief of the clinic of the faculty of medicine at Paris from 1896 to 1898.

Charcot commanded an expedition to the antarctic in the "Français," 1903–05, exploring the western side of Graham Land to 67° S. In 1908, in command of the "Pourquoi Pas?," he returned to the antarctic and spent the winter of 1909 on Petermann Island (65° S.). Further explorations south and west were made the following summer. Charcot Land, which he named after his father, was discovered, and a number of contributions to scientific research resulted from the voyage. He later did research on and made explorations to the arctic, and in 1921 he studied Rockall Island, a North Atlantic British possession.

On Sept. 16, 1936, the "Pourquoi Pas?" was wrecked off the western coast of Iceland, and 39 men, including Charcot and a number of other scientists, were lost at sea.

In addition to *Atrophie musculaire progressive* and various other works on medicine, he published *Le Français au Pôle Sud* (1906); *Le "Pourquoi Pas?" dans Antarctique* (1911; Eng. trans. 1912); *Autour du Pôle Sud*, 2 vol. (1912); and *Christophe Colomb vu par un marin* (1928).

CHARCOT, JEAN MARTIN (1825–1893). French physician was born in Paris on Nov. 29, 1825. In 1853 he took his MD at Paris, and three years later was appointed physician of the Central Hospital bureau. In 1860 he became professor of pathological anatomy in the medical faculty of Paris, and in 1862 began his connection with the Salpêtrière, where he created the great neurological clinic. As regards hysteria, which he defined as a psychosis superinduced by ideation, he threw the sexual theory into disrepute and studied the disease in relation to hypnotism. In muscular atrophy he differentiated between the ordinary wasting and the rarer amyothropic lateral sclerosis (1874) and described with Pierre Marie the progressive neural or peroneal type (1886). He differentiated the essential lesions of locomotor ataxia and described both the gastric crisis and the joint affections (Charcot's disease). He separated multiple sclerosis from paralysis agitans. In diseases of the brain, the most notable contributions were his articles on cerebral localization, the studies of aphasia and the discovery of the miliary aneurisms and their importance in cerebral haemorrhage. Charcot greatly promoted the study of medicine in art (see *Nouvelle Iconographie de la Salpêtrière*, 1888). He died on Aug. 16, 1893.

His best known works are *Leçons sur les maladies du système nerveux*, 5 vol. (1872–93) and *Leçons du mardi à la Salpêtrière*, 2 vol. (1889–90).

See F. Garrison, *Hist. of Medicine;* W. Osler in *Johns Hopkins Hospital Bulletin* (1893); F. H. Mackay and Emilie Legrand, "Jean Martin Charcot, 1825–1893," *Arch. Neurol. and Psychiat.*, 34:390–400 (1935).

CHARD, JOHN ROUSE MERRIOTT (1847–1897), British soldier, was born at Boxhill, near Plymouth, on Dec. 21, 1847, and in 1868 entered the royal engineers. In 1878 Lieut. Chard was ordered to South Africa to take part in the Zulu War, and was stationed at the small post of Rorke's Drift to protect the bridges across the Buffalo river and some sick men and stores. There, with Lieut. Gonville Bromhead (1856–91) and 80 men of the 2nd 24th foot, he heard, on Jan. 22, 1879, of the disaster of Isandhlwana from some fugitives who had escaped the slaughter. Believing that the victorious Zulus would attempt to cross into Natal they prepared, hastily, to hold the Drift until help came. They barricaded and loopholed the old church and hospital and improvised defenses from wagons, bags of Indian corn, etc.

Early in the afternoon they were attacked by more than 3,000 Zulus who, after hours of desperate hand-to-hand fighting, carried the outer defenses, an inner low wall of biscuit boxes and the hospital, room by room. The garrison then retired to the stone kraal, and repulsed attack after attack through the night.

The next morning relieving forces appeared and the enemy retired. The spirited defense of Rorke's Drift saved Natal from a Zulu invasion. The gallantry of Chard and Bromhead was rewarded with the Victoria Cross and immediate promotion to the rank of captain and brevet major. On Chard's return to England he became a popular hero. From 1893 to 1896 he commanded the royal engineers at Singapore, and in 1897 he was made a colonel. He died the same year at Hatch-Beauchamp, near Taunton, on Nov. 1.

CHARD, a market town and municipal borough in Somersetshire, England, 16 mi. S.S.E. of Taunton by road. Pop. (1951) 5,218. Area 1.6 sq.mi. It lies on a hillside close to the Devon and Dorset borders and the runnels by the sides of the main street are said to flow, one south to the English channel, the other north to the Bristol channel. Industries include agricultural machinery, surgical supplies, lace, shirts and collars and dairy produce. The town takes its name from Cerdic who founded the kingdom of Wessex, and appears as Cedre in the Domesday Book. The bishop of Bath held Chard in 1086 and in 1234 his successor granted the first charter which was confirmed in 1253 (when a Monday market and a fair on July 25 were granted), 1280 and 1285. The corporation seal dates from 1570. The town was incorporated by grant of Charles I in 1642 and Charles II gave a charter in 1683 (when two more fair days were added). The cruciform parish church of St. Mary the Virgin is Perpendicular of the 15th century. The grammar school was founded in 1671 when William Symes gave his house for the purpose. Another Tudor house is the court house of the manor which contains the room where Judge Jeffreys condemned to death 12 natives of Chard for taking part in the Monmouth rebellion.

CHARD or SWISS CHARD, a name given to the edible leaf beet (*Beta vulgaris* var. *cicla*), a variety of the beet (*q.v.*) in which the leaves and leafstalks, instead of the roots, have become greatly developed. The plant is a biennial with somewhat branched and thickened but not fleshy roots and large leaves borne on stalks sometimes 2 ft. long and 1 in. to 3 in. wide. It is grown for the tender leaves and leafstalks; the former are boiled and served like spinach, the latter, like asparagus. Swiss chard is popular as a home-garden potherb because of its ease of culture, productiveness and tolerance to moderately hot weather. It furnishes an abundance of greens after the weather becomes too warm for growing spinach and other early greens.

CHARDIN, JEAN SIMÉON (1699–1779), French *genre* painter, the son of Jean Chardin, master carpenter, was born in Paris on Nov. 2, 1699, and died Dec. 6, 1779. He became famous for his still-life pictures and domestic interiors, which are well represented at the Louvre, and for figure painting, as in his *Le Bénédicité* (1740) and is one of the great French colourists.

See A. Dayot, *J. B. Siméon Chardin* (1905); H. E. A. Furst, *Chardin* (1911); E. Pilon, *Chardin* (1911).

CHARDIN, SIR JOHN (1643–1713), French traveller, was born in Paris in 1643. His father, a wealthy jeweller, gave him an excellent education and trained him in his own art; but instead of settling down in the ordinary routine of the craft he set out in company with a Lyons merchant named Raisin in 1665 for Persia and India, partly on business and partly to gratify his own inclinations.

After a highly successful journey, during which he had received the patronage of Shah Abbas II of Persia, he returned to France in 1670, and there published in the following year *Récit du Couronnement du roi de Perse Soliman III.*

He set out again for Persia in Aug. 1671. The second journey was much more adventurous than the first for, instead of going directly to his destination, he passed by Smyrna, Constantinople, the Crimea, Caucasia, Mingrelia and Georgia. He did not reach Ispahan until June 1673. After four years spent in researches throughout Persia, he again visited India, and returned to Europe by the Cape of Good Hope in 1677. The persecution of Protestants in France led him, in 1681, to settle in London, where he was appointed jeweller to the court and was knighted by Charles II.

In 1683 he was sent to Holland as representative of the English East India company, and in 1686 he published the first part of his narrative, *The Travels of Sir John Chardin into Persia and the East Indies*, etc. (London).

Sir John died in London in 1713 and was buried in Westminster Abbey.

BIBLIOGRAPHY.—The complete account of Chardin's travels appeared at Amsterdam in 1711, under the title of *Journal du voyage du chevalier Chardin*. The Persian portion is to be found in vol. ii of Harris' *Collection* (1705), and extracts are reprinted by Pinkerton in vol. ix. The best complete reprint is by Langlès (1811).

CHARENTE, an inland department of southwestern France, comprehending the ancient province of Angoumois and small portions of Saintonge, Poitou, Marche, Limousin and Périgord. It is bounded north by the departments of Deux-Sèvres and Vienne, east by those of Haute Vienne and Dordogne, south by Dordogne and Charente-Maritime and west by Charente-Maritime. Area 2,306 sq.mi. Pop. (1946) 311,137. The Confolentais (known also as the *Terres Froides*) in the northeast is a region of granitic rocks which may be considered as a western extension of the Massif Central. There some parts exceed 1,000 ft. in height and the whole provides good upland pasture for cattle. The remainder of the department, known as the Terres Chaudes, consists of Jurassic, Cretaceous and Tertiary deposits and provides rich arable land. Cereals and potatoes are the principal crops and chestnuts, walnuts and cider apples the chief fruits. The Terre Champagne is noted for its vines, much of the wine produced being distilled into brandy named after the town of Cognac. A large area drains to the Charente river, the chief affluents of which, in this section, are the Tardoire, the Touvre and the Né. The Confolentais is watered by the Vienne, a tributary of the Loire, while the district of Barbezieux, noted for its poultry farming, belongs almost wholly to the basin of the Gironde. Charente has stone quarries, peat workings and beds of clay which supply brick and tileworks and earthenware manufactories. There is a large foundry of naval guns at Ruelle. Flour mills and leatherworks are numerous. Angoulême is a paper-making centre and manufactures gunpowder. Coal, salt and timber are prominent imports. Exports include paper, brandy, stone and agricultural products. The department is served chiefly by the Orléans and Ouest-État railways, and the Charente is navigable below Angoulême. Charente is divided into the three *arrondissements* of Angoulême, Cognac and Confolens (29 cantons, 424 communes). It belongs to the region of the 12th army corps, to the province of the archbishop of Bordeaux and to the *académie* (educational division) of Poitiers. Its court of appeal is at Bordeaux. Angoulême (*q.v.*) is the capital, and Cognac, Confolens, Jarnac (*qq.v.*) and La Rochefoucauld are other towns. The department abounds in churches of Romanesque architecture, of which those of Bassac, St. Amant-de-Boixe (portions of which are Gothic), Plassac and Gensac-la-Pallue may be mentioned. There are remains of a Gothic abbey church at La Couronne, and Roman remains at St. Cybardeaux, Brossac and Chassenon (where are ruins of the Gallo-Roman town of Cassinomagus).

CHARENTE-MARITIME, a maritime department of southwestern France, comprehending the old provinces of Saintonge and Aunis and a small portion of Poitou, and including the islands of Ré, Oléron, Aix and Madame. Area, 2,792 sq.mi. Pop. (1946) 416,187. It is bounded north by Vendée, northeast by Deux-Sèvres, east by Charente, southeast by Dordogne, southwest by Gironde and the estuary of the Gironde and west by the Bay of Biscay. The department is low lying and consists of Jurassic, Cretaceous, Tertiary and Quaternary deposits which run in a northwesterly direction. This trend can be traced also in many sections of the coast and in the islands of Oléron and Ré. Post-Pleistocene submergence has resulted in the formation of many inlets and estuaries, particularly the Gironde, and there are several good harbours, the chief of which are La Rochelle and Rochefort. The latter has developed at the expense of Tonnay-Charente which is too high up the river to cope with modern shipping. Oysters and mussels are bred in the neighbourhood of La Rochelle and Marennes and there are many fishing villages. Royan, on the north shore of the Gironde, is a much-frequented watering place. The chief crops are wheat, oats, maize, barley and potatoes. Horse and cattle raising is carried on and dairying is prosperous. A considerable quantity of wine, most of which is distilled into brandy, is produced. The department has a few peat-workings, and produces freestone, lime and cement; the salt marshes of the coast are important. Shipbuilding, iron founding, machine construction and the making of glass, pottery, bricks and earthenware are also carried on. The railways traversing the department belong to the Ouest-État system, except one section of the Paris-Bordeaux line belonging to the Orléans company. Internal communication is facilitated by the navigable reaches of the Charente, the Sèvre Niortaise, the Boutonne, the Seudre and the Gironde and by the canals of the coast. There are five *arrondissements* (40 cantons, 483 communes), cognominal with the towns of La Rochelle, Rochefort, Saintes, Saint-Jean-d'Angély and Jonzac. The department forms the diocese of La Rochelle, and is attached to the 18th military region, and in educational matters to the *académie* of Poitiers. Its court of appeal is at Poitiers. La Rochelle, Saint-Jean-d'Angély, Rochefort and Saintes are the principal towns. Surgères and Aulnay possess fine Romanesque churches. Pons has a château of the 15th and 16th centuries and a keep of the 12th century.

CHARENTON-LE-PONT, a town of northern France in the department of Seine, situated on the right bank of the Marne at its confluence with the Seine. Pop. (1946) 21,457. *Le Pont* refers to the stone bridge of ten arches which crosses the Marne and unites the town with Alfortville, well known for its veterinary school founded in 1766. In the 16th and 17th centuries Charenton was the scene of the ecclesiastical councils of the Protestant party, which had its principal church in the town. At the neighbouring St. Maurice is the well known Hospice de Charenton. Charenton has a port on the Canal de St. Maurice, besides the Marne, and carries on boatbuilding and the manufacture of tiles and porcelain.

CHARES, of Lindus in Rhodes, a sculptor pupil of Lysippus, who fashioned for the Rhodians a colossal bronze statue of the sun god, the cost of which was defrayed by selling the warlike engines left by Demetrius Poliorcetes after the siege in 303 B.C. (Pliny, *Nat. Hist.* xxxiv, 41). The colossus was seventy cubits (105 ft.) in height. The notion that it bestrode the harbour is absurd. It was thrown down by an earthquake after 56 years.

See E. A. Gardner, *Handbook of Greek Sculpture* (1915), par. 61.

CHARES, of Mytilene, a Greek belonging to the suite of Alexander the Great, to whom he was appointed court marshal. He wrote a history of Alexander in ten books, dealing mainly with the private life of the king. The fragments are chiefly preserved in Athenaeus.

See *Scriptores Rerum Alexandri* (pp. 114–20) in the Didot edition of Arrian.

CHARES, Athenian general, is first heard of in 366 B.C. as assisting the Phliasians, who had been attacked by Argos and Sicyon. In 361 he visited Corcyra, where he helped the oligarchs to expel the democrats, a policy which led to the subsequent defection of the island from Athens.

In 357 Chares was appointed to the command in the Social War, together with Chabrias, after whose death before Chios he was associated with Iphicrates and Timotheus. (For the naval battle in the Hellespont, *see* TIMOTHEUS.) Chares, having successfully thrown the blame for the defeat on his colleagues, was left sole commander; but, receiving no supplies from Athens, he joined the rebellious satrap Artabazus.

A complaint from the Persian king, who threatened to send 300 ships to the assistance of the confederates, led to the conclusion of peace (355) between Athens and its rebellious allies and to the recall of Chares.

In 349 he was sent to the assistance of Olynthus against Philip II of Macedon, but he returned without having effected anything. In the following year, when he reached Olynthus, he found it already in the hands of Philip.

In 340 he was appointed to the command of a force sent to aid Byzantium against Philip, but the inhabitants, remembering his former plunderings and extortions, refused to receive him. In 338 he was defeated by Philip at Amphissa, and was one of the commanders at the disastrous battle of Chaeroneia (*see* CHAERONEIA, BATTLE OF). Lysicles, one of his colleagues, was condemned to death, while Chares does not seem to have been even accused.

After the conquest of Thebes by Alexander (335), Chares is said to have been one of the Athenian orators and generals whose surrender was demanded. Two years later he was living at Sigeum, for Arrian (*Anabasis* i, 12) states that he went from there to pay his respects to Alexander. In 332 he entered the service of Darius and took over the command of a Persian force in Mytilene, but he capitulated on the approach of a Macedonian fleet on condition of being allowed to retire unmolested.

He is last heard of at Taenarum, and is supposed to have died at Sigeum. Although boastful and vainglorious, Chares was not lacking in personal courage and was among the best Athenian generals of his time. At the best, however, he was "hardly more than an ordinary leader of mercenaries" (A. Holm). He openly boasted of his profligacy, was exceedingly avaricious and his bad faith became proverbial.

See Diod. Sic. xv, 75, 95, xvi, 7, 21, 22, 85–88; Plutarch, *Phocion*, 14; Theopompus, *ap.* Athenaeum, xii, p. 532; *Cambridge Ancient History*, vol. vi (1927), ch. viii and ix (with useful bibliography).

CHARGE, a load (Late Lat. *carricare,* to load in a *carrus* or wagon); *cf.* "cargo," "charger," a large dish. The word is used also for the powder and shot to load a firearm, the accumulation of electricity in a battery, the necessary quantity of dynamite or other explosive in blasting and a device borne on an escutcheon in heraldry. "Charge" can mean a burden, and so a care or duty laid upon one, as in the instructions given by a judge to a jury or by a bishop to the clergy of his diocese. In the sense of a pecuniary burden the word is applied to the price of goods, to an encumbrance on property and the expense of running a business. Further uses of the word are of an attack by cavalry, by a bull or elephant or by a football player; "charger," originally a horse ridden in a charge, now means a horse ridden by an officer, whether of infantry or cavalry.

CHARGÉ D'AFFAIRES: *see* AMBASSADOR; DIPLOMACY.

CHARGER, a riding horse allotted to a military officer for war; any mechanism adapted for charging, as for placing explosives in boreholes for blasting, and that used in loading a magazine rifle or a machine gun, etc.; a large shallow dish.

CHARGING ORDER: *see* PRACTICE AND PROCEDURE.

CHARIBERT (d. 567), king of the Franks, was the son of Clotaire I. On Clotaire's death in 561 his estates were divided between his sons, Charibert receiving Paris as his capital, together with Rouen, Tours, Poitiers, Limoges, Bordeaux and Toulouse. Besides his wife, Ingoberga, he had unions with Merofleda, a wool carder's daughter, and Theodogilda, the daughter of a neatherd. He was one of the most dissolute of the Merovingian kings.

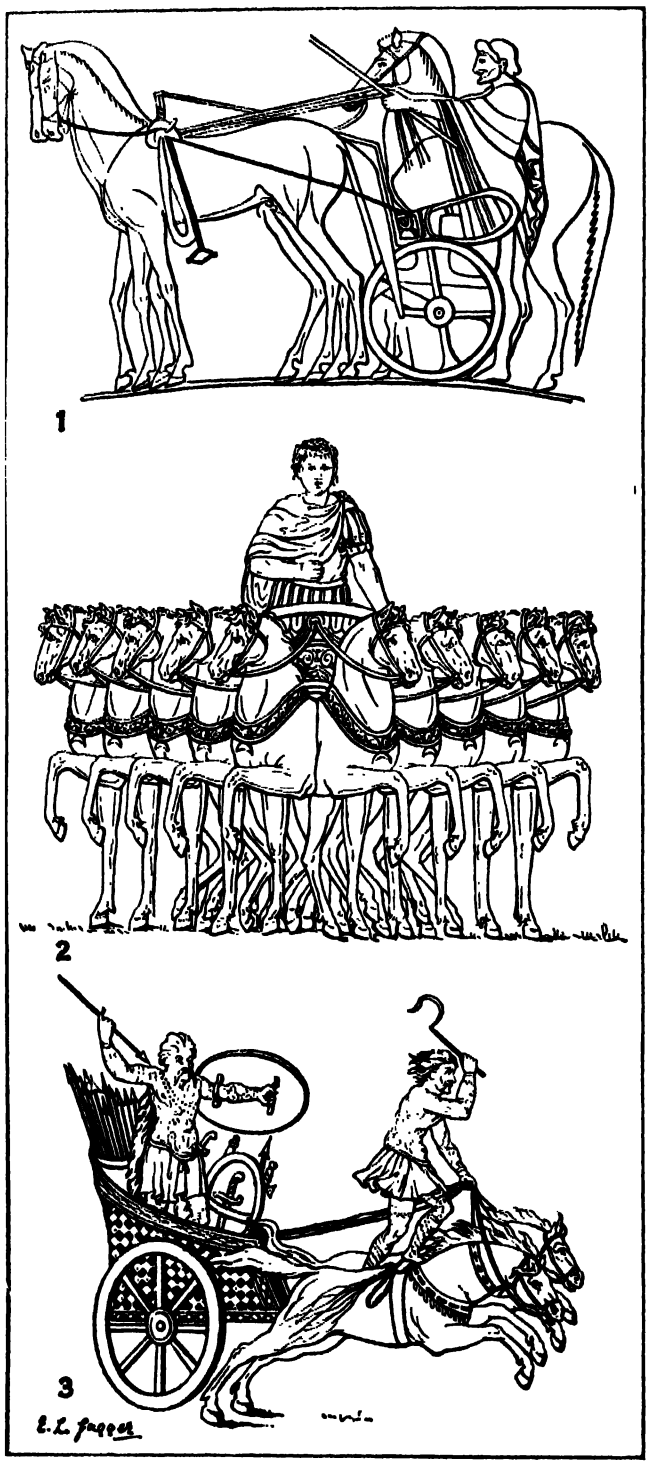
(C. PF.)

CHARIDEMUS, of Oreus in Euboea, Greek mercenary leader. He fought under the Athenian general Iphicrates against Amphipolis *c.* 367 B.C. but later joined Cotys, king of Thrace, against Athens. Soon afterward he fell into the hands of the Athenians and accepted the offer of Timotheus to re-enter their service. He was given Athenian citizenship. Having been dismissed by Timotheus (362) he joined the revolted satraps Memnon and Mentor in Asia. In 360 he was elected a *strategos.* After more service under the Athenians, he again joined Cotys, on whose murder (359) he was appointed guardian to his youthful son Cersobleptes. In 357, on the arrival of Chares with considerable forces, the Chersonese was restored to Athens. The supporters of Charidemus represented this as due to his efforts; and, in spite of the opposition of Demosthenes, he was honoured with a golden crown and it was resolved that this person should be inviolable. In 351 he commanded the Athenian forces in the Thracian Chersonese against Philip II of Macedon, and in 349 he superseded Chares as commander in the Olynthian War. He achieved little success, but made himself detested and was in turn replaced by Chares. After Chaeroneia the war party would have entrusted Charidemus with a command but the peace party secured the appointment of Phocion. He was one of those whose surrender was demanded by Alexander after the destruction of Thebes, but escaped with banishment. He fled to Darius III of Persia, who received him with distinction. But, having expressed his dissatisfaction with the preparations made by the king just before the battle of Issus (333), he was put to death.

Demosthenes, *Contra Aristocratem,* is the chief source, the other evidence is collected in A. Schäfer, *Demosthenes und seine Zeit,* 2nd ed. (Leipzig, 1885).

CHARING CROSS, the locality about the west end of the Strand and the north end of Whitehall, London, in the city of Westminster. Here Edward I erected the last of the series of crosses in memory of his queen Eleanor (d. 1290). The derivation from Edward's "dear queen" (*chère reine*) is apocryphal. The cross was destroyed in 1647, and in 1675 an equestrian statue of Charles I by Hubert LeSueur was erected at the top of Whitehall, where several regicides had been executed, at the place where the cross stood. The modern cross (1863) stands within the forecourt of Charing Cross railway station. Formerly an important terminus for the continent, the station is now mostly concerned with trains serving southern England. The name (Cyrring in 1000) may refer to the neighbouring sharp bend in the river Thames.

CHARIOT. In antiquity, a car used in battle, for the chase, in public processions and in games. The Greek chariot had two wheels and was made to be drawn by two horses; if a third, or more commonly, two reserve horses were added, they were attached on each side of the main pair by a single trace fastened to the front of the chariot, as may be seen on two prize vases in the British Museum from the Panathenaic games at Athens. On the monuments there is no other sign of traces, from the want of which wheeling round must have been difficult. Immediately on the axle (ἄξων, *axis*), without springs of any kind, rested the basket or body (δίφρος) of the chariot, which consisted of a floor to stand on and a semicircular guard round the front about half the height of the driver. It was entirely open at the back, so that the combatant might readily leap to the ground and up again as was necessary. There was no seat, and generally only room for the combatant and his charioteer to stand in. The pole (ῥυμός, *temo*) was probably attached to the middle of the axle, though it appears to spring from the front of the basket; at the end of the pole was the yoke (ζυγόν, *jugum*), which consisted of two small saddles fitting the necks of the horses and fastened by broad bands round the chest. Besides this the harness of each horse consisted of a bridle and a pair of reins, mostly the same as in use now, made of leather and ornamented with studs of ivory or metal. The reins were passed through rings attached to the collar bands or yoke, and were long enough to be tied round the waist of the charioteer in case of his having to defend himself. The wheels and body of



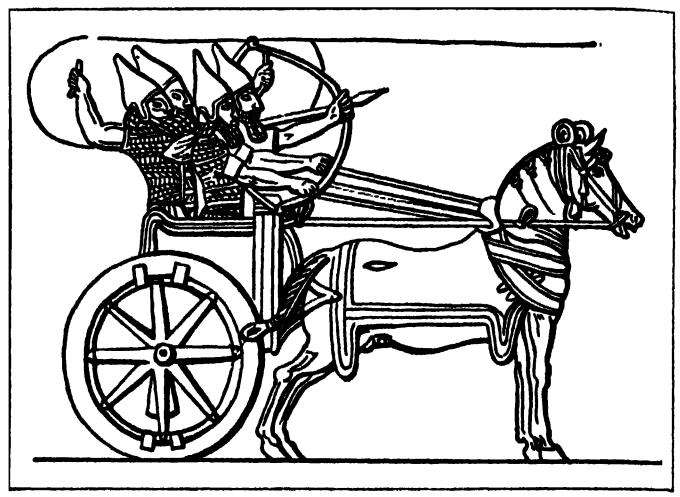
FROM DARENBERG ET SAGLIO, "DICTIONNAIRE DES ANTIQUITÉS"

A GREEK CHARIOT (REPRODUCED FROM THE MELOS VASE)

the chariot were usually of wood, strengthened in places with bronze or iron; the wheels had four to eight spokes and tires of bronze or iron. This description applies generally to the chariots of all the nations of antiquity.

Chariot Mountings.—The chariots of the Egyptians and Assyrians, with whom the bow was the principal arm of attack, were

richly mounted with quivers full of arrows, while those of the Greeks whose characteristic weapon was the spear, were plain except as regards mere decoration. Among the Persians, again, and more remarkably among the ancient Britons, there was



FROM THE "JOURNAL OF HELLENIC STUDIES"

TYPES OF CHARIOTS USED BY THREE NATIONS OF ANTIQUITY

1. Light Greek chariot equipped with four-spoked wheels (from a vase)
2. Roman chariot of the type driven in triumphal processions (from a medal of the emperor Trajan)
3. Irish chariot used in battle. Closed in the back and open in front, this model is the reverse of those employed by the Greeks, Romans and Assyrians

a class of chariot having the wheels mounted with sharp, sickle-shaped blades, which cut to pieces whatever came in their way. This was probably an invention of the Persians; Cyrus the younger employed these chariots in large numbers. Among the Greeks and Romans, on the other hand, the chariot had passed out of use in war before historical times and was retained only for races in the public games, or for processions, without undergoing any alteration apparently, its form continuing to correspond with the description of Homer, though it was lighter in build, having to carry only the charioteer. On two Panathenaic prize vases in the British Museum are figures of racing *bigae*, in which, contrary to the description given above, the driver is seated with his feet resting on a board hanging down in front close to the legs of his horses. The *biga* itself consists of a seat resting on the axle, with a

FROM DAREMBERG ET SAGLIO, "DICTIONNAIRE DES ANTIQUITÉS"

ASSYRIAN CHARIOT CARRYING BOWMEN

rail at each side to protect the driver from the wheels. The chariot was unsuited to the uneven soil of Greece and Italy, and it is not improbable that these nations had brought it with them as part of their original habits from their former seats in the east. The Jews used "iron" chariots apparently strengthened by metal.

The chief authorities are J. C. Ginzrot, *Die Wagen und Fahrwerke der Grieche und Römer* (1817); C. F. Grashof, *Über das Fuhrwerk bei Homer und Hesiod* (1846); W. Leaf in *Journal of Hellenic Studies*, v; E. Buchholz, *Die homerischen Realien* (1871-85); W. Helbig, *Das homerische Epos aus den Denkmälern erlautert* (1884), and the article "Currus" in Daremberg and Saglio, *Dictionnaire des Antiquités*.

CHARISIUS, FLAVIUS SOSIPATER, Latin grammarian, flourished about the middle of the 4th century A.D. He was probably an African by birth, summoned to Constantinople to take the place of Euanthius, a learned commentator on Terence. The *Ars Grammatica* of Charisius, part of which is still extant, is valuable as containing excerpts from the earlier writers on grammar, who are in many cases mentioned by name—Q. Remmius Palaemon, C. Julius Romanus, Cominianus.

The best edition is by H. Keil, *Grammatici Latini, i* (1857); *see* also article by G. Götz in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899); Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans.), par. 419. 1, 2; Fröhde, in *Jahr. f. Philol.*, 18 suppl., 567–672 (1892). New edition by Barwick in Teubner series (1925).

CHARITON, of Aphrodisias, in Caria, the author of a Greek romance entitled *The Loves of Chaereas and Callirrhoë*, probably flourished in the 4th century A.D. The action of the story, which is to a certain extent historical, takes place during the time of the Peloponnesian War.

Editions by J. P. D'Orville (1783), G. A. Hirschig (1856) and R. Hercher (1859); there is an (anonymous) English trans. (1764); *see* also E. Rohde, *Der griechische Roman* (1900).

CHARITON, a city of southern Iowa, U.S., 53 mi. S.E. of Des Moines; the county seat of Lucas county. It is on federal highway 34, and is served by the Burlington and Rock Island railways. The population by 1950 federal census was 5,320. Coal is mined in the vicinity, and the city has a creamery, broom factory, men's work clothing factory and a heavy iron fabrication works. It was settled about 1850.

CHARITY. The word "charity" has a wide range of meanings. It denotes the impulse to give friendship, love, aid and service. It represents, too, both a personal and a social endeavour to ameliorate the conditions which prevail in society. It stands

also for a specific association or institution designed to promote some form of social service, usually the relief of the poor.

Most of the words used in Greek, Roman or Hebrew literature to signify good will are primarily words expressive of the affections, of the relations existing between parents and children or between husband and wife, such as ἀγάπη, *amor, amicitia. Caritas* or charity, on the other hand, had a somewhat different meaning and referred rather to the relation of the individual to those outside his family; in the first instance *caritas* signified a high price, thus dearness. It was not dissimilar in meaning to the word χάρις, which also had a commercial sense but signified as well gratitude, grace, kindness. In English ecclesiastical documents it was spelled *charitas*. In the Authorized Version of the New Testament, ἀγάπη is translated "charity," and it was used by St. Paul as a translation of the Hebrew word *hesed,* which in the same version of the Old Testament is translated "mercy"; *e.g.*, "I desired mercy and not sacrifice." Almsgiving, *sedaquah,* is translated in the Septuagint by the word ἐλεημοσύνη and in the Authorized Version by the word "righteousness"; it represents the deed which is done or the gift which is made under a sense of religious obligation.

Charity therefore has no necessary relation to relief or alms. Although as a matter of fact it has largely concerned itself with the help of the class usually called the poor and with problems of distress, it is also closely allied to the sense of obligation to one's fellow men as a whole and to the view that society, acting through its appropriate organs, has a collective duty to ensure the well-being of all its members.

Early History of Charity.—To speak broadly, among simpler peoples the family unit was also the agency for sustaining those of its members who fell into distress. Thus the patriarchal family held together successive generations in one community which provided a special niche for old people, the sick and disabled widows and orphans. With the growth of cities, this form of social organization was dislocated and new methods became necessary. Sometimes, therefore, the state provided charitable aid: thus in Egypt the pharaoh and his appointed agents gave shelter to the poor and distributed bread and clothing. It was believed that charity and good works would assist the soul to attain salvation after death.

In ancient India charity was active from early times. It was promoted by the teachings of the Buddha; and the Buddhist emperor Asoka, according to one of his inscriptions, provided medical facilities throughout his realm and caused wells to be dug and trees to be planted for the enjoyment of man and beast. The infirmaries of Buddhist monasteries sometimes took patients in from outside. In Ceylon, Buddhist monks used to study medicine in order to practise it in a charitable capacity.

In China, houses of refuge for sick people existed at any rate from the introduction of Buddhism in the beginning of the Christian era. The emperor Kublai Khan in 1271 initiated a wide program of relief and social reform including the setting up of nursing establishments.

In China, however, as in many other countries, much benevolent and charitable work was also, from early times, undertaken by private agencies such as guilds and craft associations. It is typical that these paid attention not only to the material needs of the sick and infirm but also to their spiritual needs and to the religious proprieties: thus much importance was attached to the burial of deceased members in a fitting manner.

Early Greek society as mirrored in the *Odyssey* and in Hesiod's works is centred in the clan family and the phratry. Every one outside these units was a stranger: the man who had no brotherhood and was subject to no law, who had no hearth and no family, was suspect. Generally, however, the wayfarer could find food and water and shelter at the houses of the well-to-do, or he could share the hospitality of the peasants. The man who was a wayfarer and beggar almost by profession was not unknown. A system of almsgiving was recognized as a duty.

In the later Greek state, society consisted of citizens and slaves, the slaves enabling the citizens to have leisure for education, war and government. The slaves formed the greater part of the population and were permanently dependent on members of the civic class, so that the only poverty was that of the poor citizens cared for in the first instance by members of the clan family. Public policy and charity alike required that the poverty of citizens should be relieved and citizenhood preserved. In Attica the citizens were aided in various ways; *e.g.*, by legal enactments for release from debts, by emigration, by a free supply of corn, by poor relief for the infirm and by relief for the children of those fallen in war, not to speak of voluntary public service and gifts from individuals.

Three constituents of Roman life were important in their bearing on the subject of this article: the family, the plebs and slavery. The plebs, who were the clients of the great patrician families, gradually became impoverished, and slavery increased *pari passu.* The clan family in early Rome was the dominant political factor. In its development it became unsocial, and the stronger clan families crushed the weaker. The ager publicus, which belonged to the state and had in the early days been distributed to citizens without property, came more and more into the hands of the rich families, and other measures had to be taken to enable the poorer and now impoverished citizens to live. A kind of poor relief in the shape of cheap or free distribution of corn was instituted: the *annona civica.* The right to relief was dependent on the right of citizenship: it was hereditary and passed from father to son.

It was thus in the nature of a continuous endowed charity affecting not one family or group of families but the whole population. Later, for reasons of economy, it became an imperative necessity to restrict the civic bounty to as few persons as possible, and severe penalties were exacted for misappropriation. Those who received it did so as a statutory right, and no labour was required in return. The institution may be regarded less as charity than as public relief designed to allay discontent.

The *sportula* represented the charity of the patron to his clients and of the head of the clan family to those who attended at his house. During the empire particularly, leading citizens displayed munificence and benevolence in other ways: thus when new cities sprang up in the 1st and 2nd centures A.D. rich citizens gave freely for education, municipal games, etc. Some of their gifts took the form of sums of money or land for the creation and upkeep of religious or charitable institutions.

Guilds were widespread in the Roman and Hellenistic world and these conducted charitable relief for such members as had fallen upon misfortune; they cared for orphans, made loans to the needy, met the funeral expenses of members and helped widows.

Jewish ethical thought recognized from the beginning that the poor had rights and that the rich had duties. This was exemplified in injunctions such as that for the remission of debts every 7th or sabbatic year and every 50th or jubilee year; and in those governing the right of the poor to glean in the fields, the distribution of largess at weddings and at funerals and the giving of alms. Ideal and practice were continued in later Jewish history, partly because of the need for solidarity.

From the period of the fall of the Jewish state, the charity overseer was part of the recognized institutional system of every community. Numerous voluntary associations existed for the care of the indigent and unfortunate. Every ghetto had its lodging house for indigent strangers. It was laid down in the codes that a town without its proper charity organizations was no proper residence for a self-respecting Jew. It was expected of the mediaeval Jew that he should devote a tithe of his income at the very least to philanthropic objects.

Early Christianity.—In early Christian teaching charity was also given a prominent place, as a consequence of the precepts of Jesus Christ, particularly of the great commandments of St. Matthew's Gospel: "Thou shalt love the Lord thy God," "Thou shalt love thy neighbour as thyself" and "all things whatsoever ye would that men should do to you, do ye even so to them." Private liberality was encouraged; but Christianity instituted, apparently from the first, a church fund and associated charity closely with the cult and officials of the church. Gifts were brought every week or month to the service and entrusted to the president, by whom they were laid on the Lord's table and so con-

secrated to God. The recipient thus obtained them from the hand of God. The love feasts or agapae must also be mentioned among methods of maintenance: these were common meals, to which each contributed as he was able, the poor thus getting food and drink. The duty of distributing these gifts was entrusted to the deacons. The church attached particular importance to the support of widows and orphans, the sick, infirm, poor, disabled and prisoners.

After about the middle of the 4th century, both the need for charity and the means of supplying it increased. The earlier congregational method was replaced by a diocesan one: every church in a city or district was subordinated to the bishop for this purpose. He worked through his steward and could now call upon greatly increased funds. The emperor Constantine I in 321 authorized the church to receive legacies, and after this date considerable property was accumulated for the endowment of charities. As a result of these gifts numerous institutions were opened to cater for various classes of the needy or unfortunate. These included xenodochia or hostels for travellers and institutions for babies, orphans, old people, the blind and other classes. Non-Christians as well as Christians were admitted. St. Basil the Great in 370 founded a number of institutions in Caesarea for the relief of travellers, children, widows, old people, lepers, cripples and the sick. The first Christian hospital in Rome was founded toward the end of the 4th century.

In this period developed the doctrine that saw the value of charity to lie in its effect not so much on the recipient as on the giver: thus St. John Chrysostom says, "If there were no poor the greater part of your sins would not be removed; they are the healers of your wounds."

Early Islam.—Proof of the philanthropic spirit actuating the rulers and nobility of Islam is afforded by their foundation of hospitals, one of the glories of Arabic civilization. In the year 707 the caliph Al-Walid I founded at Damascus the first Arab hospital. Harun al-Rashid founded another at Baghdad in 792. The great hospital opened in Cairo in 1283 by the sultan Kala'un foreshadowed many later developments. It had special wards for dysentery cases, feverish patients, ophthalmic cases, the injured and convalescents; an organized medical service with male and female nurses; storerooms, kitchens, a dispensary, an herb garden, a library, lecture rooms and common rooms for the doctors. Storytellers and musicians were employed to amuse the patients. "I have founded this institution," wrote the sultan, "for kings and servants, for amirs and common soldiers, for rich and poor, for free and bond, for men and women alike." Indigent patients received five pieces of gold on their discharge. Famous doctors—including some Christians and Jews—attended the inpatients and also made domiciliary visits, distributing food and medicines.

The Christian Middle Ages.—At the time of Charlemagne (742?–814) the system of relief was mainly parochial and consisted principally of assistance in the home. But after that time the institutional method appears to have predominated, and the monastery or hospital in one form or another gradually encroached on the parish. Alms were distributed at the doors of churches, monasteries and wealthy houses.

In addition, large number of hospitals were set up in Christendom during the middle ages: more than 750 had been founded in England alone by 1540. Hospitals were originally places of hospitality for the needy, including travellers and the old as well as the sick; they were the ancestors of the modern almshouse as well as of the hospital. Notable English foundations were St. Bartholomew's, London, which in its early days received both the sick poor and foundling children, and St. Thomas's hospital, founded by Peter, bishop of Winchester, in 1215.

A special type of hospital was the lazar house. The first known leper hospital was founded in western Armenia between 260 and 270. Over the next 13 centuries many such institutions were established for the reception of the victims of leprosy and the diseases often mistaken for it. These might be provided by the municipal authority but were sometimes endowed by charitable individuals, the diocese or religious orders.

Domiciliary charity, which had declined after the time of Charlemagne, took on a new importance from the 12th or 13th centuries with the rise of the Franciscans and the formation of various lay orders such as the Beghards and the Alexians or Cellites who cared for the sick, the insane and young people in moral danger.

Franciscan friars also set up the first *monti di pietà* in Orvieto and Perugia (15th century).

Besides the charitable efforts of religious bodies, municipal authorities took an increasing share in promoting the welfare of their inhabitants. This naturally happened first in the countries where town life was early important: in Italy, for example, in the 9th century. By about the 13th century at the latest every urban parish in what is now Belgium had its *table du Saint Esprit* or *table des pauvres*, which was the relieving office of those times. The *chambre des pauvres* administered several parishes simultaneously, and *maîtres des pauvres*, the representatives of the *table* or *chambre*, were elected by notables. Mendicancy was controlled: only children, apprentices, old people, cripples and women with dependent children were allowed to beg. Pilgrims excepted it was still necessary for applicants for relief to be resident in the parish.

Other secular organizations with charitable activities were the merchant and craft guilds which rose to importance in the later middle ages.

The monastic system of relief began to break down a considerable time before the Reformation. The methods of charity practised by the monasteries had been indiscriminate, and their almsgiving had tended less to the relief of honest poverty than to the fostering of a class of professional beggars. As Thomas Fuller said: "The Abbeys did but maintain the poor which they made." Furthermore, the property of the hospices had often been diverted from its intended use and the hospitality of monasteries or hospices placed at the service of rich men rather than devoted to the benefit of the poor. Ecclesiastical councils and the popes themselves tried to put a stop to such abuses by threatening the administrators of hospices with heavy penalties. In 1311 the council of Vienne forbade the transformation of charitable institutions into clerical benefices and condemned the "administrators of xenodochia, lazarettos, hospices and hospitals who unfeelingly refuse to carry out founders' wishes and shamefully consume the revenues of these establishments." This edict was to be renewed by the council of Trent. In France from the time of Louis XII a series of ordinances of a similar tenor sought to reorganize the administration of such institutions and to take them out of the control of religious bodies.

The same tendencies toward decay had been found in England as in continental countries, and the suppression of the monasteries under Henry VIII and Edward VI did not destroy a system of relief that had previously been working effectively, but merely rendered more apparent the amount of pauperism that had previously existed. It is probable, however, that pauperism was increased by other factors operating at the time, such as the enclosure movement.

16th–19th Centuries.—Under Henry VIII and Edward VI the property of hospitals and guilds was in many cases confiscated. The old systems of charitable relief, for what they were worth, having thus been largely interrupted, new organizations had to be created. The only effective means of raising money for the support of the poor was, it seemed, a compulsory tax, and the administration of statutory relief naturally devolved on the central government. The principle of poor law relief from a compulsory tax having been adopted, it was enacted (1572–73) that the aged and infirm should be cared for by a new authority, the overseers of the poor; and in 1601 two more acts were passed, that for the relief of the poor (43 Eliz. 2) and that for the furtherance and protection of endowed charities (*see* below). Thus the poor were given a statutory minimum of relief which, it was expected, would be supplemented by voluntary benevolence. The poor law was philanthropic in its origin; but the philanthropy later disappeared, and the object of the law appeared to be more and more to relieve the burden of poor rates.

The history of charity from the middle of the 16th century is

a history of the remedying of deficiencies in statutory provision partly by supplementing it and partly by educating the public conscience so as to extend it. It is also a history of the discovery and investigation of new needs.

Thus poor relief was centralized and regulated in several continental cities by ordinances of the 15th and 16th centuries. Their methods however seem to have been largely palliative. A more rational method of approaching the problem was proposed by the Spanish humanist Juan Luis Vives in his book *De Subventione pauperum* (1526): this included the co-ordination of charitable activities, a census of the indigent population, detailed inquiries into individual cases and the application of measures suited to each set of circumstances and aiming at permanent rehabilitation. It had no immediate results, however. Examples of voluntary enterprise supplementing official work included an early employment exchange opened in Paris in 1630 by Théophraste Renaudot and "friendly visiting" among the poor, instituted by the preacher Thomas Chalmers (1819), by Daniel von der Heydt, author of the Elberfeld poor relief system, *q.v.* (1852), and by A. F. Ozanam, founder of the Société de Saint Vincent de Paul (1833), among others. Soup kitchens for the poor were provided by Benjamin Thompson, Count Rumford, in Bavaria around the end of the 18th century. But in general the picture until at any rate the middle of the 19th century is one of a large number of separate and often jealous organizations for the relief of the poor, pursuing many useful and some less useful lines of activity, but lacking any real knowledge of the extent and causes of poverty.

The later history of the relief of the sick exhibits also a progressively keener perception of differing needs leading to increased specialization of services. In the 17th century a clearer distinction began to be drawn between institutions where treatment was provided and those where shelter was given to the aged and the poor, but it was not until the 18th that hospitals really began to concentrate upon acute cases. At this time both the planning of hospitals and medical and nursing treatment were exceedingly rudimentary, and a long period of energetic work by devoted voluntary workers such as Claude-Humbert Piarron de Chamousset, Sir John Pringle, John Howard and Florence Nightingale was necessary to improve them. At the same time new needs were successively discovered and provided for. Medical dispensaries were set up in France in the 17th century. In London 53 well-known doctors in 1696 each subscribed £10 for the creation of a free dispensary where they offered their services. Specialized hospitals for tuberculosis, cancer, diseases of the eye and diseases of the ear and throat began to be set up in the 18th and early 19th centuries. The broadening conception of medical treatment also led, in the latter part of the 19th century, to the development of "hospital social services": in 1895 the first lady almoner was appointed at the Royal Free hospital, London; in the same year a similar post was created at the Charity hospital, Berlin; and nine years later a post-hospital relief service was organized in New York city.

Relief of the blind by alms and by shelter had existed in ancient times; but again, efforts to assist them to develop their capacities and to live as far as possible normal lives were not made until relatively late. In 1749 Denis Diderot suggested that the blind could be taught to read and write by touch. A satisfactory alphabet, however, was not achieved until the time of Louis Braille (1829). Subsequently much attention has been given to the matter of training and placing blind people. Work for the deaf, for children, for old people and for other dependent or disabled classes has followed a similar course of a more and more discriminating study of needs and of ways to meet these needs on the part of a succession of public-spirited men and women.

These forms of charity concentrated chiefly on the individual. But charitable effort also concerned itself with the improvement of the environment—with better housing, town planning and the preservation of the beauties of the countryside for the benefit of the mass of the people. In England, movements to improve the housing of the poor were largely a 19th-century phenomenon: the prince consort was president of an association founded in 1844 to provide workingmen's dwellings; and in the 1860s the Peabody trust set up for the same purpose, was followed by others. In an allied sphere of work, Octavia Hill in the 1860s invented the vocation of housing manager and exercised a remarkable educative and social influence upon her tenants. After these efforts to improve housing the wider principle began to be recalled that the improvement of the environment must take into account not only individual houses but also the town as a whole and the countryside around it.

Much charitable work in the early 19th century was carried on by individuals and societies having little connection with one another. Around the middle of the century, however, it began more and more to be felt that this lack of system led to waste of effort. Societies worked without adequate knowledge of what others were doing and without any proper examination of the circumstances of applicants. As a consequence of this feeling, a number of co-ordinating and organizing societies were set up in various parts of Europe. One of the first and best known of these was the Charity Organisation society, London, formed in 1869, at first called the Society for Organizing Charitable Relief and Repressing Mendicity. The aims of this body were avowedly to prevent the continuance of indiscriminate relief giving and the consequent pauperization of the recipients. Its methods included careful inquiries into every case, the submission of written reports by the social workers concerned and the careful discussion of facts with a view to discovering the causes of distress and planning their removal. In its early days the society incurred, rightly or wrongly, a considerable amount of antagonism from the working classes on account of its alleged harsh and unsympathetic attitude. At the same time there is no doubt that it played an important part in the investigation of the causes of poverty and associated ills and in the development of casework and other social techniques. It was also one of the first to emphasize the necessity of training for charitable work. It started training courses for social workers in 1893, an example which was followed by many other bodies throughout the world. Further advances in the systematization and effectiveness of charitable work were made during the later 19th century: thus the first large-scale survey of poverty conducted on precise methods was begun in London in 1889 by Charles Booth and was the forerunner of a host of others in many countries which were of immense value in focusing charitable effort.

The State and Voluntary Effort.—Public social service is, it will have been seen, not a new thing; what was perhaps characteristic of the 20th century was the view that it is the function of the state as the appropriate organ of society to take systematic measures to ensure adequate minimum standards and adequate social opportunities for all its members. To do so became possible partly through the increased knowledge accumulated as a result of the work referred to above.

Nevertheless, voluntary effort for social service continued to play an extremely important part in the 20th century. In Great Britain, social service bodies wholly or mainly independent of government control existed in astonishing variety—their numbers and, therefore, the aggregate of their funds being virtually impossible to determine accurately. The same richness of voluntary effort is found in many other countries: for example in Italy and in France, where their vigour is assisted by a widespread distrust of centralized bureaucracy; in Denmark, where voluntary effort is responsible for most residential institutions for children, for most day centres, such as kindergartens, and also for many institutions for the special care and rehabilitation of the handicapped; and in the Netherlands, where, as it is a principle to make use of voluntary organizations wherever possible, the public agencies supplement voluntary ones.

After World War II the future of voluntary charitable effort in Great Britain appeared somewhat uncertain. The state took over a good deal which formerly was the province of private philanthropy. Moreover, costs rose steeply, and taxation and financial stringency led to a diminution of income from donations and subscriptions. Indeed, many voluntary social service bodies were drawing an appreciable proportion of their income from central or local government sources in the form of grants-in-aid, payments for services and the like. In this way the position and the work of voluntary associations became more closely linked than before

with those of public social services. This change in position and function was assisted by legislation that made it either mandatory or permissive for public departments to make use of voluntary bodies in carrying out certain duties in the field of social welfare, such as, for example, the youth service. It was thus often difficult to say where official action ended and voluntary service began.

Charitable Endowments.—The existence of endowed charities in early and mediaeval times was referred to above. After the dissolution of the monasteries and the seizure of funds of guilds and chantries in England, the Statute of Charitable Uses (43 Eliz. 4 [1601]) was passed to provide for reform of abuses and encourage further charitable gifts. Many trusts were founded in the 17th and 18th centuries, but, consequent upon widespread maladministration by trustees, a movement for reform began in the early 19th century. In 1835 a select committee was appointed; resulting from its recommendations, an act of 1853 set up the Charity commission, which had and still had in the early 1950s the duty of watching over charitable trusts. Its powers and duties included those of inquiry into the affairs of a charity, in connection with which it could require the production of accounts; control over dealings in real estate; removal of trustees (subject to conditions); and the preparation of schemes, under certain conditions, where it appeared that the original objects of a trust could not be fulfilled. UNITED STATES

The history of charity in the United States, as elsewhere, is one of many social, religious and economic theories, influences and endeavours, all of which left their imprint on both popular and educated thought. The universal principles of Christian doctrine which were a fusion of the Jewish and Graeco-Roman philosophies obtained.

The structure of charity organization in the United States had its origin largely in the English system; the American poor laws followed English legislation and practice until about the early 19th century. Most of the states even in the second half of the 20th century continued to cling to many of the old Elizabethan poor law principles in philosophy and practice. The principle of settlement or legal residence as a requirement for receiving assistance still prevailed generally. States had fluctuated in their adherence to the old English principle of relative responsibility, but on the whole it still had public acceptance. There had never been any question of the moral or ethical responsibility to support needy close relatives, but in practice the attempt to enforce this as a legal obligation had been filled with heartaches, damaged familial relationships, costly judicial procedures and withal very little money resulting from court action for the support of the dependent [illegible]

The English poor law principle of "less eligibility" also continued to permeate popular belief regarding charity and public assistance in the United States—that is, the recipient of charity should not receive in assistance more than an amount the lowest paid worker can earn. Inherent in this principle is the fear that the individual would prefer to receive charity rather than to work. This attitude had prevailed especially with reference to the unemployed, able-bodied man.

Yet, experience both in the United States and England had disproved this theory. Experience had shown that assistance which does not allow the recipient and his family to function as self respecting members of the community tends to pauperize rather than the contrary. Likewise, when assistance is given in a positive way the recipient is in a better position to become a self-supporting and self-respecting person.

In the development of U.S. public charitable activity until about the middle of the 19th century, there was an almost complete disregard of the effect of charity on the beneficiary. Charity of this early period was largely motivated by communal purposes or class interests as contrasted with the personal concern and gratification of early ecclesiastical charities.

The growing private charitable activities of this period did not differ much from those of the various governmental bodies since they, too, were nourished by the mounting wealth of the industrial middle class. The addition to charitable theory and practice of a genuine interest in the individual recipient and of the recognition of his rights as a person did not come until near the close of the 19th century.

Individuals such as Joseph Tuckerman, Thomas Eddy, Samuel Gridley Howe, Dorothea Dix and Charles Loring Brace made important contributions to this new and important concept of charity. Early antecedents of modern family service societies likewise contributed. From the early 1840s until about 1877 these societies played major roles in the giving of relief and in charitable reform. They worked for the breakdown of the old traditional concept of the poor as a class apart from the rest of the population. They protested against indiscriminate giving of charity and attempted to devise methods of preventing it. They worked toward the development of the scientific method in the administration of charity. Some of the recommendations of the early societies were quite in advance of the times. They proposed to divide the cities into small districts, each district to have two or three volunteer visitors who were to call on the poor in their own homes, thereby having close contact with and first-hand knowledge of the applicant and later the recipient. Some of the societies proposed to promote life insurance and savings banks, to prohibit street begging and to establish houses of employment for those who could not find work. They devised a plan whereby all spontaneous charity could flow into one channel for distribution. Many of the early attempts failed, however, because they lost purpose and direction as they gave more attention to agitating for temperance rather than charitable reform, thus tending to confuse moral objectives with the relief of physical want.

Efforts at charitable reform continued, however, and in 1877 the Charity Organization Societies movement started. Its objectives included co-operation between all charitable agencies in a local community; full and accurate knowledge of individuals receiving service; adequate and prompt relief; employment for all able and willing to work; establishment of relations of personal interest and sympathy between the poor and the well-to-do; and collection and dissemination of knowledge about administration of charity. The study of causes of individual failure to adjust to family or to the social environment led the Charity Organization societies to the realization that help must come from persons who had studied social sciences and the available knowledge of human relations. This realization hastened the transition from a service by volunteer friendly visitors to one carried on more and more by salaried workers with professional training.

Types.—By the second half of the 20th century the charitable activities of individuals varied greatly in the United States. To many people, charity was little more than a series of miscellaneous activities described vaguely as doing good or as helping people—giving clothing or baskets of food to the poor at Christmas, pro-

viding free medical and dental care for the sick poor and clothing and recreation for poor children. Others might not give food, clothing or money directly to the beneficiary but rather give their personal contributions to a social agency which in turn served the needy person. Others, as members of a church, might contribute to the operation of a charitable institution maintained by the church. Clubs or other social organizations might sponsor entertainments to raise money for various charitable purposes. While the philosophy inherent in public assistance was not fundamentally the same as the traditional concept of private charity, public relief was still popularly confused with charity. The scope of charity had undergone many changes with regard to potential beneficiaries, and the types of benefits had reflected the changing social standards of the communities. To some individuals, the giving of charity may involve a real personal feeling of responsibility with an attempt to understand and meet the needs of those who receive charity regardless of the form it takes or the way in which it is administered. Modern social work practice indicated that those who are most understanding of the emotional and psychological needs of people and the problems involved in receiving charity are willing to have social agencies with professionally trained staffs give the service and financial assistance to the recipient. The individual donor may implement his own charitable impulses not only by giving money to the agency but by such voluntary activity as serving on committees of the social agency.

By mid-20th century in the United States, individuals only rarely sought out the beneficiaries of their own charitable acts. To organize charity is to give to it an ordered nature and definite purpose and to associate members of the community together for the purpose. Private charitable giving for welfare purposes in the United States is largely channeled through the community chest or some similar agency which is organized to collect voluntary contributions through a single annual campaign. Through some such organization as the Council of Social Agencies, welfare and health services are co-ordinated to prevent duplication and overlapping of services.

Religious Charities.—The profession of the Roman Catholic faith obligates the communicant to works of charity. The basic Catholic theory for social service is stimulated in every phase of the church organization. The world-wide structure of the church permits universal teaching regarding charity to be brought to every individual member of the church. Each parish, diocese and province recognizes the corporate responsibility for social service. The standards of modern scientific social work are accepted in general by Catholic social work up to the beginning of the supernatural element, which is always regarded as superior and implies the highest kind of inspiration and aspiration for the services to others.

The title Catholic Charities is usually used to designate the federation of the Catholic social services in a diocese. This is the official agency of the bishop which plans, directs and coordinates all charitable activities in the diocese. It is customary to delegate the actual administration of the Catholic Charities to a priest trained in social work.

Jewish social work has its origins in biblical injunctions and practice. While these practices were modified to meet changing needs, the old traditions persisted. The scope and structure of Jewish social work is determined largely by the character of the Jewish population and by the community in which they live; there is no hierarchy as in Catholic social work and the local agency is autonomous and fully independent. In earlier days, Jewish agencies took pride in taking care of their own, but later they accepted the belief that most of the needs of people must be met by public welfare and that the main function of Jewish social work is to supplement governmental services. In many ways the basic core of Jewish social service is the following statement from the Talmud: "The noblest charity is to prevent a man from accepting charity and the best alms are to enable a man to dispense with alms."

Protestant churches also offer a variety of social services, but their basic theological teaching is that members should support, financially and morally, not only their own church agencies, but also those of the general community which are nonsectarian in nature. The organized social services of the Protestant churches are manifestations, in varying degrees, of the following religious motives: Christian charity and the personal concern of the church for its own people; the evangelistic hope that the religious life of the individual given service will be strengthened; and a widely humanitarian and democratic concern for the welfare of people and the general improvement of society and the concept of good works.

Child and Family Welfare.—There are many areas in which organized U.S. private social work functions, but in general, they may all be classified either as: (1) child welfare services; or (2) services to families and adults. The great concern over the welfare of children was expressed in the several White House conferences called by different presidents of the United States. The first conference in 1909 was chiefly concerned with the problems of neglected, dependent and handicapped children. Out of that conference came the United States children's bureau, established to study the needs of children and to set standards for children's services. Thereafter, White House conferences were called every ten years by the president, each one studying children's needs from increasingly broad perspectives. In 1950, for example, more than 5,000 adults and youths gathered in Washington, D.C., to consider the needs of children in the United States and territories. Two documents, the Children's charter in 1930, and the Pledge to Children in 1950, represented the philosophy of a nation toward its children.

Services to families and individuals comprise the second large area of U.S. welfare. As stated earlier, the antecedents of the private family welfare agency in the United States played an important role historically in meeting the needs of people and in the organization of charity. As the need for better trained workers became apparent, training courses for staff workers were organized by some of the larger societies. In 1898 the New York City Community Organization society inaugurated the New York School of Philanthropy, first professional school of social work. The modern family service agency is a highly specialized treatment agency offering its services on a selective basis to families with problems of emotional and personality adjustments rather than mainly financial needs.

CHARITY COMMISSIONERS FOR ENGLAND AND WALES. As a result of the reports of a committee of the house of commons appointed in 1816 on the motion of Henry (afterward Lord) Brougham, four successive statutory commissions were appointed between 1818 and 1835, the fourth expiring on July 1, 1837. The reports of these commissions are known as the Parliamentary Reports of the Former Commissioners for Inquiring Concerning Charities. They form the main source of information about charities then in existence. There followed many attempts to pass legislation to give effect to the suggestions made by the members of the fourth commission in their final general report and by a select committee of the house of commons appointed in 1835 to examine the reports of the statutory commissions so far as then published. In 1853 the first Charitable Trusts act was passed, which established the Board of Charity Commissioners for England and Wales.

Under the 1853 act and the Charitable Trusts Amendment act

1855, the functions of the charity commissioners were: (1) to inquire into the administration of charities; (2) to give advice to trustees of charities; (3) to assist trustees in developing the property and in executing the trusts of charities by supplementing their powers where defective; (4) to control the action of the trustees of charities in dealing with the corpus of endowments, the commissioners' consent being required to sales, mortgages and long leases of land; (5) to control the taking of legal proceedings on behalf of charities, so as to prevent unnecessary litigation and its attendant cost; (6) to secure the rendering of annual accounts. Later, various statutes conferred additional functions on the commissioners.

The object of the Charitable Trusts acts, 1853 to 1939, was to secure the better administration of endowed charities. The acts accordingly provided for control of dealings with capital endowments, required the rendering by trustees of annual accounts, gave the charity commissioners wide powers of inquiry and provided means of vesting property, appointing and removing trustees and remodelling trusts without resort to expensive legal proceedings. The charity commissioners were not themselves empowered, however, to administer or manage charitable trusts. Educational charities were made subject to the jurisdiction of the minister of education.

The Official Trustee of Charity Lands, a corporation sole, was constituted to hold charity lands which might be vested in him by a court of competent jurisdiction or by an order of the charity commissioners. The Official Trustees of Charitable Funds, who are incorporated, were constituted to hold stocks, shares securities and monies belonging to charities. On Dec. 31, 1952, they held a total of £119,707,852. These were holding trustees only and could not enter into the administration or management of any charity.

CHARIVARI, a French term of uncertain origin, but probably onomatopoeic, for a mock serenade, "rough music," made by beating on kettles, fire irons, tea trays or tin pans. The charivari was anciently in France a regular wedding custom, all bridal couples being thus serenaded. Later it was reserved for ill-assorted and unpopular marriages and as a mockery for all who were unpopular. At the beginning of the 17th century, wedding charivaris were forbidden by the council of Tours, but the custom still lingers in rural districts. The French of Louisiana and Canada introduced the charivari into America, where it became known under the corrupted name of "shivaree."

CHARKHARI, a town in southern Uttar Pradesh, India, 40 mi. W. of Banda. The population in 1941 was 12,638.

Ghee and cloth fabrics are produced there.

Charkhari was the capital of the former Indian state of the same name in the Bundelkhand agency of Central India. The state, which was surrounded on all sides by other states of Central India except near the town of Charkhari, where it met the former United Provinces, was founded by Bijai Bahadur, a *sanad* being granted him in 1804 and another in 1811.

In 1948 the state of Charkhari became part of the new state of Vindhya Pradesh, and two years later a detached part was merged with a district of Uttar Pradesh.

CHARLATAN, originally one who "patters" to a crowd to sell his wares (Ital. *ciarlatano,* from *ciarlare,* to chatter), like a "cheap-jack" or "quack" doctor—"quack" being similarly derived from the noise made by a duck; so an impostor who pretends to have some special skill or knowledge.

CHARLEMAGNE LEGENDS. Innumerable legends soon gathered round the memory of the great emperor. He was represented as a warrior performing superhuman feats, as a ruler dispensing perfect justice, and even as a martyr suffering for the faith. It was confidently believed towards the close of the 10th century that he had made a pilgrimage to Jerusalem; and, as in the case of many other great rulers, it was reported that he was only sleeping to awake in the hour of his country's need. The legendary Charlemagne and his warriors were endowed with the great deeds of earlier kings and heroes of the Frankish kingdom, for the romancers were not troubled by considerations of chronology. National traditions extending over centuries were grouped round Charlemagne, his father Pippin, and his son Louis. The history of Charles Martel especially was absorbed in the Charlemagne legend. But if Charles's name was associated with the heroism of his predecessors he was credited with equal readiness with the weaknesses of his successors. In the histories of the wars with his vassals he is often little more than a tyrannical dotard, who is made to submit to gross insult. This picture of affairs is drawn from later times, and the sympathies of the poet are generally with the rebels against the monarchy.

Charlemagne's wars in Italy, Spain and Saxony formed part of the common epic material, and there are references to his wars against the Slavs; but especially he remained in the popular mind as the great champion of Christianity against the creed of Mohammed. In 1164 Charles was canonized; yet this gave him no real claim to saintship, but his festival was observed in some places until comparatively recent times. Charlemagne was endowed with the good and bad qualities of the epic king, and as in the case of Agamemnon and Arthur, his exploits paled beside those of his chief warriors. These were not originally known as the peers famous in later Carolingian romance. The peers numbered 12 most probably by analogy with the 12 Apostles. The lists of them are very various, but all include the names of Roland and Oliver. The chief heroes who fought Charlemagne's battles were Roland; Ganelon, afterwards the traitor; Turpin, the fighting archbishop of Reims; Duke Naimes of Bavaria, the wise counsellor who is always on the side of justice; Ogier the Dane, the hero of a whole series of romances; and Guillaume of Toulouse, the defender of Narbonne.

The defeat of Roncesvalles, which so deeply impressed the popular mind, has not a corresponding importance in real history. But it chanced to find as its exponent a poet whose genius established in the *Chanson de Roland* (*see* ROLAND, LEGEND OF) a model for his successors, and definitely fixed the type of later heroic poems. The other early *chansons* to which reference is made in *Roland* are *Aspremont, Enfances Ogier, Guiteclin, Balan,* relating to Charlemagne's wars in Italy and Saxony. *Basin* or *Carl et Elégast* (preserved in Dutch and Icelandic), the *Pèlerinage de Charlemagne* and *Le Couronnement Looys* also belong to the heroic period. The purely fictitious and romantic tales added to the personal history of Charlemagne and his warriors in the 13th century are inferior in manner, and belong to the decadence of romance. The old tales, very much distorted in the 15th century prose versions, were to undergo still further degradation in 18th century compilations.

According to *Berte aus grans piés,* in the 13th century *remaniement* of the Brabantine *trouvère* Adenet le Roi, Charlemagne was the son of Pippin and of Berte, the daughter of Flore and Blanchefleur, king and queen of Hungary. *Mainet* (12th century) and the kindred poems in German and Italian relate the *enfances* (youthful exploits) of Charlemagne. He delivered Rome from the besieging Saracens, and returned to France in triumph. But his wife Galienne, daughter of Galafre, whom he had converted to the Christian faith, died on her way to rejoin him. Charlemagne then made an expedition to Italy (*Enfances Ogier* in the Venetian *Charlemagne,* and the first part of the *Chevalerie Ogier de Dannemarche* by Raimbert of Paris, 12th century) to raise the siege of Rome, which was besieged by the Saracen emir Corsuble. *Aspremont* (12th century) describes a fictitious campaign against the Saracen King Agolant in Calabria, and is chiefly devoted to the *enfances* of Roland. The wars of Charlemagne with his vassals are described in *Girart de Roussillon, Renaut de Montauban, Huon de Bordeaux,* and in the latter part of the *Chevalerie Ogier,* which belong properly to the cycle connected with Doon of Mayence.

The legend of the pilgrimage of Charlemagne to the Holy Sepulchre probably originated in a desire to authenticate the relics in the abbey of Saint Denis, supposed to have been brought to Aix by Charlemagne, and is preserved in a 12th-century romance, *Le Pèlerinage de Charlemagne.* The legend of the conquest of Armorica is preserved in *Aiquin* (12th century). *La destruction de Rome* is a 13th-century version of the older *chanson* of the emir Balan, who collected an army in Spain and sailed to Rome. The defenders were overpowered and the city destroyed before the

advent of Charlemagne, who, however, avenged the disaster by a great battle in Spain. The romance of *Fierabras* (13th century) was one of the most popular in the 15th century, and by later additions came to have pretensions to be a complete history of Charlemagne. *Otinel* (13th century) is also pure fiction. *L'Entrée en Espagne*, preserved in a 14th-century Italian compilation, relates the beginning of the Spanish War, the siege of Pampeluna, and the legendary combat of Roland with Ferragus. Charlemagne's march on Saragossa, and the capture of Huesca, Barcelona and Girone, gave rise to *La Prise de Pampelune* (14th century, based on a lost *chanson*); and *Gui de Bourgogne* (12th century) tells how the children of the barons, after appointing Guy as king of France, set out to find and rescue their fathers, who are represented as having been fighting in Spain for 27 years. The *Chanson de Roland* relates the historic defeat of Roncesvalles on Aug. 15, 778, and forms the very crown of the whole Carolingian legend. The two 13th-century romances, *Gaidon* and *Anseis de Carthage*, contain a purely fictitious account of the end of the war in Spain, and of the establishment of a Frankish kingdom under the rule of Anseis. Charlemagne was recalled from Spain by the news of the outbreak of the Saxons. The contest between Charlemagne and Widukind (*Guiteclin*) offered abundant epic material. Unfortunately the original *Guiteclin* is lost, but the legend is preserved in *Les Saisnes* (*c.* 1300) of Jehan Bodel, which is largely occupied by the loves of Baudouin and Sibille, the wife of Guiteclin. The adventures of Blanchefleur, wife of Charlemagne, form a variation of the common tale of the innocent wife falsely accused, and are told in *Macaire* and in the extant fragments of *La Reine Sibille* (14th century). After the conquest of the Saracens and the Saxons, the defeat of the Northmen, and the suppression of the feudal revolts, the emperor abdicated in favour of his son Louis (*Le Couronnement Looys*, 12th century). Charles's harangue to his son is in the best tradition of epic romance. The memory of Roncesvalles haunts him on his death-bed, and at the moment of death he has a vision of Roland.

The mythic element is practically lacking in the French legends, but in Germany some part of the Odin myth was associated with Charles's name. The constellation of the Great Bear, generally associated with Odin, is Karlswagen in German, and Charles's Wain in English. There were mediaeval chroniclers who did not fear to assert that Charles rose from the dead to take part in the Crusades. In the ms. *Annales S. Stephani Frisingenses* (15th century), which formerly belonged to the abbey of Weihenstephan, and is now at Munich, the childhood of Charlemagne is practically the same as that of many mythic heroes. This work, generally known as the chronicle of Weihenstephan, gives among other legends a curious history of the emperor's passion for a dead woman, caused by a charm given to Charles by a serpent to whom he had rendered justice. The charm was finally dropped into a well at Aix, which thenceforward became Charles's favourite residence. The story of Roland's birth from the union of Charles with his sister Gilles, also found in German and Scandinavian versions, has abundant parallels in mythology, and was probably transferred from mythology to Charlemagne.

The Latin chronicle, wrongly ascribed to Turpin (Tilpinus), bishop of Reims from 753 to 800, was in reality composed by a Frenchman between 1140 and 1150. Alberic Trium Fontium, a monk of the Cistercian monastery of Trois Fontanes in the diocese of Châlons, embodied much poetical fiction in his chronicle (*c.* 1249). A large section of the *Chronique rimée* (*c.* 1243) of Philippe Mousket is devoted to Charlemagne's exploits. At the beginning of the 14th century Girard of Amiens made a dull compilation known as *Charlemagne* from the *chansons de gests*, authentic history and the pseudo-Turpin. *La Conqueste que fit le grand roi Charlemaigne es Espaignes* (pr. 1486) is the same work as the prose compilation of *Fierabras* (pr. 1478), and Caxton's *Lyf of Charles the Grete* (1485).

The Charlemagne legend was fully developed in Italy, where it was to have later a great poetic development at the hands of Boiardo, Ariosto and Tasso. There are two important Italian compilations, ms. XIII. of the library of St. Mark, Venice (*c.* 1200), and the *Reali di Francia* (*c.* 1400) of a Florentine writer, Andrea da Barberino (b. 1370), edited by G. Vandelli (Bologna, 1892). The six books of this work are rivalled in importance by the ten branches of the Norse *Karlamagnus saga*, written under the reign of Haakon V. This forms a consecutive legendary history of Charles, and is apparently based on earlier versions of the French Charlemagne poems than those which we possess. It thus furnishes a guide to the older forms of stories, and moreover preserves the substance of others which have not survived in their French form. A popular abridgement, the *Keiser Karl Magnus Krönike* (pr. Malmö, 1534), drawn up in Danish, serves in some cases to complete the earlier work. The 2,000 lines of the German *Kaiserchronik* on the history of Charlemagne belong to the first half of the 12th century, and were perhaps the work of Conrad, the poet of the *Ruolantes Liet*. The German poet known as the Stricker used the same sources as the author of the chronicle of Weihenstephan for his *Karl* (*c.* 1230). The earliest important Spanish version was the *Chronica Hispaniae* (*c.* 1284) of Rodrigo de Toledo.

The French and Norman-French *chansons* circulated as freely in England as in France, and it was therefore not until the period of decadence that English versions were made. The English metrical romances of Charlemagne are:—*Rowlandes Song* (15th century); *The Taill of Rauf Coilyear* (*c.* 1475, pr. by R. Lekpreuik, St. Andrews, 1472), apparently original; *Sir Ferumbras* (*c.* 1380) and the *Sowdone of Babylone* (*c.* 1400) from an early version of *Fierabras;* a fragmentary *Roland and Vernagu* (Ferragus); two versions of *Otuel* (Otinel); and a *Sege of Melayne* (*c.* 1390), forming a prologue to Otinel unknown in French.

For the historical Charlemagne *see* CHARLES THE GREAT.

BIBLIOGRAPHY.—The most important works on the Charlemagne cycle of romance are J. Bédier, *Les légendes épiques* (4 vol., 1908–13) and *La Chanson de Roland* (1927), and for the German legend, vol. iii. of H. F. Massmann's ed. of the *Kaiserchronik* (Quedlinburg, 1849–54). *The English Charlemagne Romances* were edited (extra series) for the Early Eng. Text Soc. by Sidney J. Herrtage, Emil Hausknecht, Octavia Richardson and Sidney Lee (1879–81), the romance of *Duke Huon of Bordeaux* containing a general account of the cycle by Sidney Lee; the *Karlamagnussaga*, by C. R. Unger (Christiania, 1860), *see* also G. Paris in *Bibl. de l'Ecole des Chartes* (1864–65). For individual *chansons see* L. Gautier, *Les Épopées françaises* (new ed. 1919 etc.) and J. Bédier, *op. cit.*, to which the following should be added: A. Thomas, *L'Entrée d'Espagne* (Société des Anciens Textes Français, 1913); L. Brandin, *La Chanson d'Aspremont* (1923–24), and *Sir Otuel*, ed. S. J. Herrtage (*E.E.T.S.*, 1880). For the Carolingian romances relating to Roland, *see* ROLAND, LEGEND OF; *Les Saisnes*, ed. F. Michel (1839); *The Sege of Melaine*, introductory to *Otinel*, preserved in English only (ed. *E.E.T.S.*, 1880); *Simon de Pouille*, analysis in *Epop. fr.* (iii. pp. 346 *seq.*); *Voyage de C. à Jérusalem*, ed. E. Koschwitz (Heilbronn, 1879). For the chronicle of the Pseudo-Turpin, *see* an edition by Castets (Paris, 1881) for the "Société des langues romanes," and J. Bédier in *Légendes épiques*, t. iii. The Spanish versions of Carolingian legends are studied by Milà y Fontanals, *De la poesia heroico-popular castellana* (Barcelona, 1874). (L. B.)

CHARLEMONT, JAMES CAULFEILD, 1ST EARL OF (1728–1799), Irish statesman, son of the third viscount Charlemont, was born in Dublin on Aug. 18, 1728, and succeeded his father as fourth viscount in 1734. Lord Charlemont is historically interesting for his political connection with Flood and Grattan. For various early services in Ireland he was made an earl in 1763, but he disregarded court favours and cordially joined Grattan in 1780 in the assertion of Irish independence, being chosen commander-in-chief of the volunteer force. He was president of the volunteer convention in Dublin in November 1783, and was a strong opponent of the proposals for the Union. Lord Charlemont was a cultivated man, with liberal and artistic tastes, and his house was a centre of literary society in Dublin. He died on Aug. 4, 1799.

See F. Hardy, *Memoirs of the political and private life of James Caulfeild, Earl of Charlemont* (1810; 2nd ed., 1812); *Original Letters, principally from Lord Charlemont, . . . Edmund Burke, . . . etc.* (1820).

CHARLEROI (CAROLUS REX), a town in the province of Hainaut, Belgium. Pop. (1939) 28,183. It was founded in 1666 on the site of a village called Charnoy, by the Spanish governor Roderigo, and named after his sovereign Charles II. of Spain. Charleroi is the centre of the chief coalfield of Belgium, with im-

portant metallurgical and glass industries. It is connected by canal with Brussels, and from its position on the Sambre communicates by water with France. It was ceded soon after its foundation to France by the treaty of Aix-la-Chapelle, and Vauban fortified it. During the French occupation the town was considerably extended, and its fortifications strengthened to resist the attacks of William of Orange. In 1794 Charleroi again fell into the hands of the French, and it was dismantled by them. In 1816 it was re-fortified under Wellington's direction, but was finally dismantled in 1859. Parts of the old ramparts are left near the railway station. The battle of Charleroi (Aug. 22–23, 1914) was fought between German and French troops. In World War II, Charleroi was occupied by the Germans soon after the fall of Namur in May 1940.

CHARLEROI, a borough of Washington county, Pennsylvania, U.S.A., on the Monongahela river, 29 mi. S. of Pittsburgh; served by the Pennsylvania railroad. The population in 1950 was 9,864 and was 10,784 in 1940 by the federal census. It is in the "Pittsburgh" coal field, and has important manufactures of glass products (Corning Glass works). Charleroi was founded in 1890 and named for Charleroi, Belgium, whence some of the city's early glassworkers emigrated.

CHARLES, a masculine proper name (Fr. *Charles;* Span. *Carlos;* Ital. *Carlo;* Ger. *Karl*), meaning originally "man." It has been borne by many European sovereigns and princes.

CHARLES (1525–1574), cardinal of Lorraine, French statesman, was the second son of Claude of Lorraine, duke of Guise, and brother of Francis, duke of Guise. He was archbishop of Reims in 1538 and cardinal in 1547. At first he was called the cardinal of Guise, but in 1550, on the death of his uncle John, cardinal of Lorraine, he in his turn took the style of cardinal of Lorraine. A master of intrigue, he was, like all the Guises, ambitious and devoid of scruples. With his brother, Duke Francis, the cardinal was all-powerful during the reigns of Henry II. and Francis II.; in 1558 and 1559 he was one of the negotiators of the treaty of Cateau-Cambrésis; he persecuted the reformers pitilessly and helped to provoke the crisis of the wars of religion. The death of Francis II. deprived him of power, but he remained one of the principal leaders of the Catholic party. In 1561, at the Colloquy of Poissy, he was commissioned to reply to Theodore Beza (*q.v.*). In 1562 at the Council of Trent, he at first defended the rights of the Gallican Church against the pretensions of the pope; but after the assassination of his brother he approached the court of Rome, and on his return to France he endeavoured, in vain, to obtain the promulgation of the decrees of the council (1564). In 1567, when the Protestants took up arms, he held for some time the first place in the king's council, but Catherine de' Medici soon grew weary of his arrogance and in 1570 he had to leave the court. He endeavoured to regain favour by negotiating at Rome the dispensation for the marriage of Henry of Navarre with Margaret of Valois (1572). He died on Dec. 26, 1574, at the beginning of the reign of Henry III.

A large amount of correspondence is preserved in the Bibliothèque Nationale. *See* also J. J. Guillemin, *Le Cardinal de Lorraine* (1847); René de Bouillé, *Histoire des ducs de Guise* (1849); H. Forneron, *Les Guises et leur époque* (1877); H. N. Williams, *The Brood of False Lorraine* (1918).

CHARLES, ST., called THE GOOD (le Bon), or THE DANE (*c.* 1084–1127), count of Flanders, was the only son of St. Canute or Knut IV., king of Denmark, by Adela, daughter of Robert the Frisian, count of Flanders. On the assassination of Canute in 1086, his widow fled to Flanders, with her son. Charles was brought up by his mother and grandfather, Robert the Frisian, on whose death he did great services to his uncle, Robert II., and his cousin, Baldwin VII., counts of Flanders. Baldwin died of a wound in 1119, and, having no issue, left his countship by will to Charles the Dane. Charles had to fight for his heritage, but he soon won, and secured his position by his clemency. He devoted himself to the welfare of his subjects, and exerted himself in the cause of Christianity, both by his bounty and by his example. He well deserved the surname of *Le Bon.* He refused the crown of Jerusalem on the death of Baldwin, and in 1125 nomination as a candidate for the imperial crown in succession to Henry V. He was murdered while praying in the church of St. Donatian at Bruges on March 2, 1127, because, by throwing open granaries there in a famine, he had broken the merchants' monopoly.

See J. Perneel, *Histoire du Règne de Charles le Bon, précédé d'un résumé de l'histoire de Flandres* (Brussels, 1830), and *Charles le Bon, Comte de Flandre* (Lille, 1853).

CHARLES THE GREAT (CHARLEMAGNE), king of the Franks and emperor, born April 2, 742 or 743, was the eldest son of Pepin III. by Berta (Bertrada), daughter of Charibert of Laon. At that date the Franks were governed by Pepin and his brother Carloman, who ruled as mayors of the palace under a fainéant Merovingian king. By the abdication of Carloman, in 747, Pepin became sole ruler, as his father Charles Martel had been. In 751 Pepin deposed the last Merovingian (Childeric III.) and himself assumed the Frankish crown, with the approbation of Pope Zacharias. In 754 Pope Stephen II. visited Pepin at Paris and anointed him as king, together with his two sons, Charles and Carloman. Between these two the kingdom was equally divided by Pepin on his death-bed (768), Charles receiving Austrasia, Neustria and western Aquitaine. This arrangement was displeasing to his junior, who perhaps claimed the whole inheritance on the ground that he was born after their father's coronation (751). In 769 Charles suppressed an Aquitanian rising, led by the aged Duke Hunold, and received the submission of Lupus, duke of Gascony, although Carloman declined to give any assistance. In 770 Charles married the daughter of Desiderius, king of the Lombards, probably to strengthen the influence which Pepin III. had acquired in Italian politics. But in 771 he repudiated the Lombard princess and married Hildegarde, a Suabian lady, who became the mother of his three legitimate sons, Charles, Pepin and Lewis. Desiderius naturally resented the slight put upon his daughter and seized the first opportunity of revenge. This presented itself in 771, when King Carloman died and Charles, in accordance with Frankish law, appropriated the vacant kingdom to the exclusion of his brother's infant sons. Their mother, Queen Gerberga, fled with them to the court of Desiderius, who announced his intention of supporting their claims and vainly urged the pope to crown them (772). Hadrian, who had lately succeeded Stephen II., endangered the safety of the papal States by refusing this demand, since Charles was preoccupied with his first Saxon campaign, and Desiderius plundered and conquered at his will in central Italy. But in the autumn of 772 Charles gave ear to Hadrian's appeal for help, and demanded satisfaction from the Lombards for himself and for the pope. Since Desiderius was defiant, the Frankish host was summoned to meet at Geneva in May 773. From Geneva the main army, led by Charles himself, marched over the Mt. Cenis to Susa, where it encountered the Lombard army, under Desiderius, holding a fortified position, and was brought to a halt. Meanwhile a second Frankish army, which had crossed the Great St. Bernard, threatened the communications of the Lombards, who as soon as they perceived their danger fell back in haste, some to Pavia and others to Verona. Verona surrendered to the Franks in the winter of 773–774, and here the nephews of Charles fell into his hands. Their fate is uncertain, but they troubled him no more. Pavia was reduced, after a long blockade, in the following summer. Desiderius, who was found there, ended his days as a monk at Corbie on the Somme. After the fall of Pavia Charles took the title of king of the Lombards. Frankish garrisons and Frankish officials were established at Pavia and in other cities of the kingdom. But some of the Lombard dukes in north and central Italy were allowed to remain in office as vassals of the conqueror. The ducal house of Benevento remained *de facto* independent, though in 788 the reigning duke agreed to pay an annual tribute, to date his charters by the regnal years of Charles, and to inscribe the name of Charles upon his coinage. Charles abstained from meddling with the Greek possessions in south Italy—Calabria, Apulia, Naples, Salerno, Amalfi. But later in his reign he acquired the Greek provinces of Venetia, Istria and Dalmatia. His relations with the papacy were defined during a visit which he paid to Rome at the Easter feast of 774. He was then acclaimed as Patrician of the Romans, and he confirmed the so-called Donation of 754 by which his father had guaranteed to the papacy its ancient and law

ful possessions in Italy. The text of the Donation only survives in a corrupt and interpolated copy. It cannot have been precisely worded since Hadrian and Charles, who were otherwise good friends, differed sharply about its interpretation. As Patrician, Charles claimed the right of hearing appeals from the Roman law-courts, and he exacted an oath of allegiance from the Romans when Hadrian's successor was elected, though he did not interfere with the election. In 800 he presided over the tribunal before which Leo III. purged himself of various accusations. But it was Lewis the Pious who first established (in 824) the right of the emperor to supervise the temporal administration of the pope through an envoy permanently residing in Rome.

From 774 to 799 Charles was at war with the Saxons, a heathen race whose lands lay east of the Rhine and north of Hesse and Thuringia. Though troublesome neighbours of the Franks they had become tributaries of Pepin III. in 758, and the Frankish annalists do not explain the first Saxon war of Charles (in 772) by reference to any provocation that he had received. Their paganism may have been their chief offence; the chief event of the campaign was the destruction of the sacred pillar Irminsul, together with its grove and temple. The Saxons retaliated by raiding Hesse while Charles was absent in Italy, and on his return, in 775, he opened a war of conquest which was only completed in the 14th campaign. There was no cohesion between the Saxon tribes, and they were much inferior to the Franks in military science and equipment. But their country had strong natural defences (the hills and forests of the Teutoburger Wald and the Harz country, the Weser and the Elbe with their tributary streams) which made it difficult for the Franks to invade rapidly or to retreat with impunity. The Frankish host was only available in the summer months, and it was difficult to find garrisons for conquered districts. The Saxons usually offered submission when they were attacked in force, and rebelled again when Charles withdrew his forces. He did not make his difficulties lighter when he insisted that those who submitted should accept baptism. His chief opponent was the Westphalian chieftain Widukind who, in 778, raided the east bank of the Rhine up to Coblenz, and, in 782, destroyed a Frankish punitive force in Saxony. The second of these exploits was atrociously revenged in the massacre of Verden, where Charles put to the sword no less than 4,500 Saxon captives in one day. In 785 Widukind submitted upon terms and was baptized, after Charles had wintered in Saxony, and had harried the land continuously for some months. After this year the chief centres of resistance were the marshes on the left bank of the lower Elbe and Nordalbingia (Schleswig). To these districts Charles applied in 799 and 804 a policy of deportations, transplanting combatants and non-combatants alike to other parts of his empire. He legislated for the conquered lands on more than one occasion. His *Capitulatio de Partibus Saxoniae* (probably of 785) denounces penalties of the severest kind against idolators and those who wrong churches or ecclesiastics; it also obliges the whole population to pay tithes to the Church. His *Capitulare Saxonicum* (797), issued after consultation with representatives of the Saxons, modifies in some respects the customary law of the race, to make it conformable with Frankish law. The customary law itself is recorded in his *Lex Saxonum*, of uncertain date. Charles founded in Saxony the bishoprics of Munster, Minden, Osnabrück, Paderborn and Bremen. He appointed Saxon nobles as his counts, and required them to hold law-courts in the Frankish manner. He directed the clergy to report to himself those counts who perverted the course of justice. In or before 797 he began to send his *missi dominici* to perambulate in Saxony. No public assembly of the Saxons was lawful unless convoked by these officials. Under this system Saxony was tranquil after 804. In the ninth century the Saxons, while retaining much of their primitive law and culture, became fervently Christian and thoroughly reconciled to Frankish rule.

Bavaria was annexed by Charles more easily and earlier than Saxony. Tassilo, the last Bavarian duke of the Agilolfing line received the duchy in 748 from the hands of Pepin III., to whom he took the oath of fealty; but he persistently absented himself from the annual assembly, and took no part in the campaigns of Pepin or of Charles. Under pressure he renewed his fealty in 781 and 787. But on the second occasion he only took the oath when the Frankish host was on the march to invade Bavaria, and in 788 he was indicted before the assembly for conspiring with the Avars. His life was spared, but he was relegated to a monastery, and Bavaria was divided between Frankish counts. In the 9th century the Bavarians were the chief support of the East Frankish monarchy and Regensburg was the chief residence of Lewis the German. As the master of Bavaria Charles came into collision with the Avars, who had been settled in the Hungarian steppes since 568. In 791 he harried their western lands, between the rivers Enns and Raab. The fortified camp (Ring) of the Avar Khan was sacked in 795 by the Margrave Eric of Friuli, and totally destroyed by Pepin, the second son of Charles in 796. After this disaster the Avars sent to Aachen certain of their chiefs who made peace and accepted baptism. Bishop Arno of Salzburg was commissioned by Charles to convert the Avar nation, and in 805 the Khan, finding himself hard pressed by the Slavs, became a Christian and placed himself under the emperor's protection.

More celebrated, but historically less important, than this easterly expansion of Frankish power is the campaigning with which Charles and his lieutenants harassed the Arabs of northern Spain. In 778 Charles himself commanded an expedition against Saragossa. It was a failure, since he did not receive the support which he had expected from some rebellious emirs. As he was retreating through the Pyrenees his rear-guard was destroyed, not by the Arabs, but by the Christian Basques of Pampeluna, whom he had exasperated by destroying the walls of that city. Einhard the biographer of Charles, treats this disaster as insignificant; but the fate of Roland, the Warden of the Breton march, who fell at Roncevaux with other famous warriors (Aug. 15, 778), passed into legend and song. To repair his relations with the Spanish Christians Charles took their side in the Adoptianist controversy, when they indicted the archbishop of Toledo as a heretic. He desired to create a Frankish march on the south slope of the Pyrenees, as an outwork for the defence of Narbonne and Septimania; and in this object he succeeded. In 801 Barcelona was captured by his son Lewis with the help of Count William of Toulouse, a hero whose name, like that of Roland, lives in mediaeval epic. In 807 Pampeluna accepted the protection of Charles and became the second bastion of the "Spanish Mark," which effectively defended both the western and the eastern passes of the Pyrenees.

Only thrice between 774 and 779 did Charles revisit Italy. In each case his primary object was to tighten his hold upon the Lombard kingdom. In 775 he crushed a Lombard rebellion in which the dukes of Friuli, Chiusi and Spoleto were supported by their compatriot, the independent ruler of Benevento; Rotgaud of Friuli lost his duchy, and Hildebrand of Spoleto, who had placed himself under the Pope's protection in 773, was forced to become a royal vassal. In 780 and in 787 Charles crossed the Alps to assert his supremacy over Benevento, an object, which, as already noted, he did not completely realize. During the second of these three visits he induced Pope Hadrian to crown his sons Pepin and Lewis as kings of Italy and Aquitaine. The Teutonic lands he reserved for himself and for his eldest son and namesake. These arrangements suggest that Italian affairs did not occupy the first place in his thoughts and calculations; and it is significant that, even after his imperial coronation, he held to the plan of 780. In this same year, while still in Italy he accepted the suggestion of the Empress Irene that his eldest daughter Rotrude should marry Irene's son and ward, the young Constantine VI. But Charles repudiated this arrangement in 787, probably because Irene and her son in that year induced the Seventh Council of Nicaea to restore image worship in the Greek Church, and called upon the Latin Church to imitate a policy which Charles and the Frankish clergy regarded as superstitious and absurd. Pope Hadrian, whose legates were present at the Council of Nicaea, agreed with its decision, but his wishes were ignored by the king. In 794 Charles held a council of the Frankish Church at Frankfurt to refute the worshippers of images. It was attended by Papal envoys and representatives of the Italian, Spanish, and English clergy. The arguments on which Charles and his advisers

relied are set forth in the *Libri Carolini*, four tracts composed in the years 789–791 by the king's orders, and published in his name. It is uncertain whether Charles was inspired by religious zeal or by a desire to discredit the Greek empire. The *Libri Carolini* expressly dispute the right of Constantine VI. to be regarded as the lawful heir of the *Imperium Romanum;* but there is no other evidence to suggest that Charles at this time coveted the imperial dignity. Perhaps the long struggle for the extirpation of Saxon idolatry was responsible for the vigour with which he and the Frankish Church pursued this controversy. There was no irremediable rupture of relations with the Greek empire; for in 798 Irene sent ambassadors to Aachen to inform Charles that Constantine VI. had been deposed and that she had been acknowledged as her son's successor. Among the Frankish clergy it appears to have been the accepted view that Constantine was infamously treated and that a woman was incapable of holding the empire. There is nothing to suggest that Irene's ambassadors were discourteously received. But in 800 Charles allowed himself to be crowned as emperor at Rome by Pope Leo III.

The secret history of this coronation, and the motives of those who counselled it, can only be conjectured. Leo III., the successor of Hadrian, was freely elected by the Roman clergy and people in 795. Charles readily acknowledged the validity of the election, but until 799 we hear of no further correspondence between the papal and the Frankish courts. In 799 a Roman faction, who accused Leo of adultery and perjury, endeavoured to get rid of him. Brutally assaulted in the streets of Rome, he narrowly escaped the loss of tongue and eyes and was confined in a Roman monastery; but his attendants succeeded in conveying him to the Duke of Spoleto for protection. Leo's character was unfavourably judged by some of the Frankish clergy; for which reason Charles declined to reinstate him until the accusations of his enemies were disproved. In July 799 Leo was brought to the king at Paderborn, ostensibly as an honoured guest, and remained there for some days. He was finally sent back to Rome, escorted by a commission of archbishops, bishops and counts, who held a judicial enquiry and reported that nothing had been proved against the Pope. In Nov. 800 the king appeared at Rome, and spent more than three weeks in reviewing the situation. His chief difficulty, we are told, was still to decide how he would deal with the pope. No accuser dared to state a case against Leo, but it is evident that he was not generally popular in Rome. At last, on Dec. 23, Leo cleared himself in St. Peter's church, taking a solemn oath upon the Gospels, that he was innocent. On Christmas Day, after celebrating mass in the same church, he crowned Charles as emperor in the presence of the Roman people who were evidently not taken by surprise, since they acclaimed Charles in the set form of words which was used to welcome a patrician. Two theologians of the emperor, Anghilbert and Alcuin prophesied obscurely (in prose and verse) the imperial coronation some months before it actually occurred. Charles may have hesitated to run the risk of a war with Constantinople; but the biographer's statement, that he was crowned unawares and against his will, is not convincing.

Once crowned, he showed himself ready and eager to come to some arrangement with Constantinople. In 801 he made an offer of marriage to Irene, but she was deposed shortly after his envoys arrived at the Greek court. They were well treated by her successor Nicephorus I., who made counter-proposals for an honourable peace between West and East. Charles responded amicably and proposed a boundary line which would have given him Venetia, and the coast towns of Istria and Dalmatia. But Nicephorus preferred to fight for these newly lost provinces, and there ensued a naval war in the Adriatic, conducted on the Frankish side by King Pepin. After the death of Pepin (July 8, 810) Charles hurriedly offered peace, with the surrender of all his claims to the disputed territories. The offer was accepted by Michael Rhangabé, who succeeded Nicephorus in 811; and in 812 Greek envoys came to Aachen and saluted the emperor of the West as *Basileus*, thus acknowledging the equality of the two empires. In view of these facts it cannot reasonably be contended that Charles regarded the Roman empire as indivisible.

In 806 Charles, in accordance with Frankish custom, drew up a scheme for the partition of his realms between his three legitimate sons. It provided that each son should be absolute in his own sphere, and did not designate a successor to the empire. But in 813, when peace had been made with Constantinople, and Charles the Young and Pepin were dead, he nominated Lewis the Pious as his consort and successor in the empire, at the same time assigning Italy to Bernhard the son of Pepin. Charles thus asserted the hereditary character of the empire. It is remarkable that the coronation of Lewis took place, not at Rome, but at Aachen, and that Charles himself placed the crown upon his son's head, as if with the intention of showing to the world that the pope had no voice in the disposal of the empire. Next to the Greeks the Danes were the chief enemies with whom Charles had to deal in his last years. A Danish kingdom was already in existence, and it menaced his north-eastern frontier; Danish pirates were already harrying the British Isles. In 809 Charles built a fort at Itzehoe to protect the right bank of the Elbe. In 811 and 812 he concluded treaties with Danish kings. But he relied especially upon his North sea fleet which was based upon Boulogne, and built in his shipyards at Ghent. He ordered that ships should be found for defence of all ports and navigable rivers on his northern coasts. He also maintained patrols in the Mediterranean from Narbonne to the mouth of the Tiber, to guard against the descents of Arab pirates, but the danger from this side did not engage his personal attention. By capitularies of 802 and 811 he made naval service obligatory on all the inhabitants of maritime provinces, even upon the magnates. It was no fault of his that the Franks failed to create a strong naval power against the evil days that were in sight.

The reign of Charles witnessed a revival of arts and letters in Francia. Illuminators, goldsmiths, workers in ivory and metal reached a high degree of skill, although the higher arts were still neglected, and the emperor's chapel at Aachen was adorned with pillars and bronze portals fetched from Rome and Ravenna. Among the Frankish clergy scholarship was encouraged in the reign of Pepin, by the king himself and by the Englishman Boniface, archbishop of Mainz. Charles stimulated the clergy to further efforts. He himself studied Latin grammar with Peter of Pisa, rhetoric and dialectic and astronomy with Alcuin of York, and he listened with attention while his clerks read to him works of history or St. Augustine's *De Civitate Dei*. The effect of classical studies, upon Charles himself and his advisers, is revealed in his legislation which is more grammatically and intelligently composed than those of his predecessors. He aspired to emulate the legislators of Constantinople. Though he never attempted to make a code, he revised the laws of the Salian and Ripuarian Franks, and caused those of the Saxons, Thuringians and Frisians to be written down. His Capitularies, which were binding on his subjects without respect of race, supply a remarkable conspectus of Frankish institutions. In these texts we can study the duties of his counts and *missi*, the functions of the local law courts and assemblies, the law of vassalage, the rights of exempted estates (*immunitates*), the composition of the national host; the *Capitulare de Villis* even supplies full information concerning the management of the royal demesnes. The credit for the details of this legislation is due to the arch-chaplain and the clerks of the royal chaplain, ecclesiastics who were trained in seminaries of the Carlovingian renaissance. By his *Admonitio Generalis* (789) Charles required that every bishop should test the theological education of his priests, and that reading schools should be everywhere established. For a select minority a higher type of education was provided in cathedral schools, such as those of Orleans and Lyons, and in such monastic schools as those of Tours, Corbie, St. Riquier, Metz and St. Wandrille. The Palace school, a Merovingian institution, was reorganized by Alcuin in the years 782–796. In it were educated the emperor's children, the sons of great nobles and also some ecclesiastics who afterwards did much to promote the new studies, as for example Adalhard of Corbie and Anghilbert of St. Riquier. The Palace school declined after the death of Charles, but the new cathedral and monastic schools produced a remarkable race of literati. To the libraries founded

in connection with such schools we are indebted for the oldest extant manuscripts of Caesar, Sallust, Lucretius, Tacitus and Suetonius, and many of the works of Cicero. In the emperor's lifetime, and with his encouragement, the text of the Latin Vulgate was restored to a purer form by Alcuin and other scholars. One of these recensions not the work of Alcuin, was officially recommended to the Frankish bishops by the encyclical *De Emendatione Librorum* (*c.* 787). The scholars whom Charles patronized are well remembered as excellent grammarians. In their hands Latin became once more a polished and flexible medium of literary expression. The thoughts which they expressed in copious prose and verse are often banal pleasantries or insipid exhortations. Alcuin's letters, a few topical poems by Alcuin and Theodulf of Orleans, and the biography of Charles by Einhard, one of the royal clerks, are the cream of this Carolingian literature.

At Aachen he built a palace (of which no trace is left) and a chapel which, with many alterations and restorations, is incorporated in the existing cathedral. He commenced to build another palace at Ingelheim near Mainz, which was the great bridge-head for his armies, and a third at Nymwegen (near the Saxon border) of which the chapel, consecrated by Leo III., is the only relic. For three years, 792–794, he settled at Regensburg, the old Bavarian capital, but this step was taken for political and military reasons. At Aachen he was in his homeland. The forests of the neighbourhood gave him good hunting; with his sons and his nobles and his bodyguards he bathed and swam in the hot springs which still feed the *Kaiserbad*. In his dress, as in his pastimes, he affected the old Frankish mode, and he disdained elaborate banquets, preferring a simple, heavy meal at which the staple dish was broiled venison, served to him on the spit by his huntsmen. When business of State was in hand he was prompt, methodical and labourious. He prided himself on the magnificent furniture of his chapel and on the decorum with which its services were celebrated. He kept to the end his interest in scholarship and in theology, and left a large library of manuscripts. But his private life was lax in one respect. Though a devoted husband to three of his four wives, he had illegitimate offspring by five mistresses. His court was dissolute and the conduct of his daughters caused grave scandals.

Charles died on Jan. 28, 814, after four years of failing health, from an attack of pleurisy. He was buried in the chapel at Aachen, probably in the antique sarcophagus which is preserved there; this at all events is the coffin in which his bones were found in 1165, when they were disinterred by Frederick Barbarossa.

CHARLES II.,[1] called THE BALD (823–877), Roman emperor and king of the West Franks, the son of the emperor Louis the Pious, was born in 823. The death of the emperor in 840 was the signal for the outbreak of war between his sons. Charles allied himself with his brother Louis the German to resist the pretensions of the emperor Lothair, and the two allies conquered him in the bloody victory of Fontenoy-en-Puisaye (June 25, 841). In the following year the two brothers confirmed their alliance by the celebrated oaths of Strasbourg (*see* FRANCE: *History*). The war was brought to an end by the treaty of Verdun (Aug. 843), which gave to Charles the Bald the kingdom of the western Franks, which practically corresponded with what is now France, as far as the Meuse, the Saône and the Rhone, with the addition of the Spanish March as far as the Ebro. The first years of his reign up to the death of Lothair I. (855) were comparatively peaceful, and during them was continued the system of "confraternal government" of the sons of Louis the Pious, who had various meetings with one another, at Coblenz (848), at Meersen (851), and at Attigny (854). In 858 Louis the German invaded the kingdom of Charles. In 860 he in his turn tried to seize the kingdom of his nephew, Charles of Provence, but met with a repulse. On the death of Lothair II. in 869 he tried to seize his dominions, but by the treaty of Meersen (870) was compelled to share them with Louis the German. Besides this, Charles had to struggle against the incessant rebellions in Aquitaine, against the Bretons, who inflicted on the king the defeats of Ballon (845) and Juvardeil (851), and especially against the Normans, who devastated the country in the north of Gaul, the valleys of the Seine and Loire, and even up to the borders of Aquitaine. Charles led various expeditions against the invaders, and tried to put a barrier in their way by having fortified bridges built over all the rivers. In 875, after the death of the emperor Louis II., Charles the Bald, supported by Pope John VIII., descended into Italy, receiving the royal crown at Pavia and the imperial crown at Rome. But Louis the German revenged himself for Charles's success by invading and devastating his dominions. Charles was recalled to Gaul, and after the death of Louis the German (Aug. 28, 876), in his turn made an attempt to seize his kingdom, but at Andernach met with a shameful defeat (Oct. 8, 876). In the meantime, John VIII., who was menaced by the Saracens, was continually urging him to come to Italy, and Charles again crossed the Alps. At the same time Carloman, son of Louis the German, entered northern Italy. Charles started on his way back to Gaul, and died while crossing the pass of the Mont Cenis, Oct. 5 or 6, 877. He was succeeded by his son Louis the Stammerer.

BIBLIOGRAPHY.—The most important authority for the history of Charles's reign is represented by the *Annales Bertiniani*, which were the work of Prudentius, bishop of Troyes, up to 861, then up to 882 of the celebrated Hincmar, archbishop of Reims. This prince's charters are to be found published in the collections of the *Académie des Inscriptions*, by M. M. Prou. The most complete history of the reign is found in E. Dümmler, *Geschichte des ostfränkischen Reiches* (3 vols., Leipzig, 1887–88). *See* also J. Calmette, *La Diplomatie carolingienne du traité de Verdun à la mort le Charles le Chauve* (Paris, 1901), and F. Lot, "Une Année du règne de Charles le Chauve," in *Le Moyen-Âge* (1902), pp. 393–438; F. Lot and L. Halphen, *Le Règne de Charles le Chauve* (1909); M. Jusselin, *La Chancellerie de Charles le Chauve d'après les notes tironiennes* (1922).

CHARLES III., THE FAT (832–888), Roman emperor and king of the West Franks, was the youngest of the three sons of Louis the German, and received from his father the kingdom of Swabia (Alamannia). After the death of his two brothers in succession, Carloman (880) and Louis the Young (882), he inherited the whole of his father's dominions. He was crowned emperor at Rome by Pope John VIII. (Feb. 881). On his return to Germany he led an expedition against the Norsemen of Friesland, but instead of engaging with them he preferred to make terms and paid them tribute. In 880 the death of Carloman brought into his possession the west Frankish realm, and in 885 he got rid of his rival Hugh of Alsace, an illegitimate son of Lothair II. In spite of six expeditions into Italy, he did not succeed in pacifying the country, nor in delivering it from the Saracens. He was equally unfortunate in Gaul and in Germany against the Norsemen, who in 886–887 besieged Paris. The emperor appeared before the city with a large army (Oct. 886), but contented himself by buying the retreat of the invaders at the price of a heavy ransom, and his permission for them to ravage Burgundy without his interfering. On his return to Alamannia the general discontent showed itself openly and a conspiracy was formed against him. He was deposed by an assembly which met at Frankfürt or at Tribur (Nov. 887), and died in poverty at Neidingen on the Danube (Jan. 18, 888).

CHARLES IV. (1316–1378), Roman emperor and king of Bohemia, the eldest son of John of Luxemburg, king of Bohemia,

[1] For Charles I., Roman emperor, *see* CHARLES THE GREAT; *cf.* under Charles I. of France below.

and Elizabeth, sister of Wenceslas III., was born at Prague on May 14, 1316, and in 1323 went to the court of his uncle, Charles IV., king of France, where he remained for seven years. He married Blanche, sister of King Philip VI., the successor of Charles IV. In 1333 he was made margrave of Moravia. Three years later he undertook the government of Tirol on behalf of his brother John Henry, and was soon actively concerned in a struggle for the possession of this country. In consequence of an alliance between his father and Pope Clement VI., the relentless enemy of the emperor Louis IV., Charles was chosen German king in opposition to Louis by some of the princes at Rense on July 11, 1346. Confirming the papacy in the possession of wide territories, he promised to annul the acts of Louis against Clement, to take no part in Italian affairs, and to defend and protect the church. In 1346 he fought at Crécy, where his father was killed. As king of Bohemia he returned to Germany, and after being crowned German king at Bonn on Nov. 26, 1346, prepared to attack Louis. After the death of the emperor in October 1347 Charles was soon the undisputed ruler of Germany.

In 1350 the king was visited at Prague by Cola di Rienzi, who urged him to go to Italy, where the poet Petrarch and the citizens of Florence also implored his presence. Charles kept Rienzi in prison for a year, and then handed him over to Clement at Avignon. Four years later, however, he crossed the Alps without an army, received the Lombard crown at Milan on Jan. 6, 1355, and was crowned emperor at Rome by a cardinal on April 5. On his return Charles was occupied with the administration of Germany, then just recovering from the Black Death, and in 1356 he promulgated the Golden Bull (*q.v.*) to regulate the election of the king. He was unremitting in his efforts to secure other territories and to strengthen the Bohemian monarchy. To this end he purchased part of the upper Palatinate of the Rhine in 1353, and in 1367 annexed Lower Lusatia to Bohemia and bought numerous estates in various parts of Germany. On the death in 1363 of Meinhard, duke of Upper Bavaria and count of Tirol, Upper Bavaria was claimed by the sons of the emperor Louis IV., and Tirol by Rudolph IV., duke of Austria. Both claims were admitted by Charles on the understanding that if these families died out both territories should pass to the house of Luxemburg. About the same time he was promised the succession to the margravate of Brandenburg, which he actually obtained for his son Wenceslas in 1373. He also gained a considerable portion of Silesian territory, partly by inheritance through his third wife, Anna, daughter of Henry II., duke of Schweidnitz. In 1365 Charles visited Pope Urban V. at Avignon and undertook to escort him to Rome; and on the same occasion was crowned king of Burgundy, or Arles, at Arles on June 4, 1365. During his later years the emperor took little part in German affairs beyond securing the election of his son Wenceslas as king of the Romans in 1376, and negotiating a peace between the Swabian league and some nobles in 1378. After dividing his lands between his three sons, he died on Nov. 29, 1378, at Prague, where he was buried.

Charles, who according to the emperor Maximilian I. was the step-father of the empire, but the father of Bohemia, brought the latter country to a high state of prosperity. In 1348 he founded the university of Prague, and afterwards made this city the seat of an archbishop. He was an accomplished diplomatist, possessed a penetrating intellect, and was capable of much trickery in order to gain his ends. He was superstitious and peace-loving, had few personal wants, and is described as a round-shouldered man of medium height, with black hair and beard, and sallow cheeks.

His autobiography, the "Vita Caroli IV.," which deals with events down to the year 1346, and various other documents relating to his life and times, are published in the *Fontes rerum Germanicarum*, Band I., edited by J. F. Böhmer (Leipzig, 1885). For other documents relating to the time see *Die Regesten des Kaiserreichs unter Kaiser Karl IV.*, edited by J. F. Böhmer and A. Huber (Innsbruck, 1889); *Acta Karoli IV. imperatoris inedita* (Innsbruck, 1891); E. Werunsky, *Excerpta ex registris Clementis VI. et Innocentii VI.* (Innsbruck, 1885). *See* also E. CHARLES V. (1500–1558), Roman emperor and (as Charles I.) king of Spain, was born in Ghent on Feb. 20, 1500. His parents were Philip of Burgundy and Joanna, third child of Ferdinand and Isabella. Philip died in 1506, and Charles succeeded to his Netherland possessions and the county of Burgundy (Franche Comté). His grandfather, the emperor Maximilian, as regent, appointed his daughter Margaret vice-regent, and under her strenuous guardianship Charles lived in the Netherlands until the estates declared him of age in 1515. In Castile, Ferdinand, king of Aragon, acted as regent for his daughter Joanna, whose intellect was already clouded. On Jan. 23, 1516, Ferdinand died. Charles's visit to Spain was delayed until the autumn of 1517, and only in 1518 was he formally recognized as king conjointly with his mother, firstly by the cortes of Castile and then by those of Aragon. Joanna lived to the very eve of her son's abdication, so that he was only for some months technically sole king of Spain. During this Spanish visit Maximilian died, and Charles succeeded to the inheritance of the Habsburgs, to which was shortly added the duchy of Württemberg. Maximilian had also intended that he should succeed as emperor. In spite of the formidable rivalry of Francis I. and the opposition of Pope Leo X., pecuniary corruption and national feeling combined to secure his election in 1519. Charles hurriedly left Spain, and after a visit to Henry VIII. and his aunt Catherine was crowned at Aix on Oct. 23, 1520.

The difficulty of Charles's reign consists in the complexity of interests caused by the unnatural aggregate of distinct territories and races. The Crown of Castile brought with it the two recently conquered kingdoms of Navarre and Granada, together with the new colonies in America and scattered possessions in northern Africa. That of Aragon comprised the three distinct States of Aragon, Valencia and Catalonia, and in addition the kingdoms of Naples, Sicily and Sardinia, each with a separate character and constitution of its own. No less than eight independent cortes or parliaments existed in this Spanish-Italian group, adding greatly to the intricacy of government. In the Netherland provinces again the tie was almost purely personal; there existed only the rudiments of a central administration and a common representative system, while the county of Burgundy had a history apart. Much the same was true of the Habsburg group of States, but Charles soon freed himself from direct responsibility for their government by making them over, together with Württemberg, to his brother Ferdinand. The empire entailed serious liabilities on its ruler without furnishing any reliable assets; only through the cumbrous machinery of the diet could Charles tap the military and financial resources of Germany. His problem here was complicated by the growth of Lutheranism, which he had to face at his very first diet in 1521. In addition to such administrative difficulties Charles had inherited a quarrel with France, to which the rivalry of Francis I. for the Empire gave a personal character. Almost equally formidable was the advance of Sultan Suleiman up the Danube, and the union of the Turkish naval power with that of the Barbary States of northern Africa. Against Lutheran Germany the Catholic emperor might hope to rely upon the pope, and against France on England. But the attitude of the popes was almost uniformly disagreeable, while from Henry VIII. and Edward VI. Charles met with more unpleasantness than favour.

The difficulty of Charles himself is also that of the historian and reader of his reign. It is probably more instructive to treat it according to the emperor's several problems than in strict chronological order. Yet an attempt to distinguish the several periods of his career may serve as a useful introduction. The two best dividing lines are, perhaps, the coronation as emperor at Bologna in 1530, and the peace of Crépy in 1544. Until his visit to Italy (1529) Charles remained in the background of the European stage, except for his momentous meeting with Luther

at the diet of Worms (1521). This meeting in itself forms a subdivision. Previously to this, during his nominal rule in the Netherlands, his visit to Spain and his candidature for the Empire, he seemed, as it was said, spell-bound under the ferule of his minister Chièvres. Almost every report represented him as colourless, reserved and weak. His dependence on his Flemish counsellors provoked the rising in Castile, the feebleness of his government the social war in Aragon. The religious question first gave him a living interest, and at this moment Chièvres died. Aleander, the papal nuncio at Worms, now recognized that public opinion had been wrong in its estimate of Charles. Never again was he under tutelage. The necessity, however, of residence in Spain prevented his taking a personal part in the great fight with Francis I. for Italy. He could claim no credit for the capture of his rival at Pavia. When his army sacked Rome and held Pope Clement VII. prisoner, he could not have known where this army was. And when later the French overran Naples, and all but deprived him of his hold on Italy, he had to instruct his generals that they must shift for themselves. The world had become afraid of him, but knew little of his character. In the second main division of his career Charles changed all this. No monarch until Napoleon was so widely seen in Europe and in Africa. At the head of his army Charles forced the Turks backwards down the Danube (1532). He personally conquered Tunis (1535), and was only prevented by "act of God" from winning Algiers (1541). The invasion of Provence in 1536 was headed by the emperor. In person he crushed the rebellion of Ghent (1540). In his last war with Francis (1542–44) he journeyed from Spain to the Netherlands, brought the rebellious duke of Cleves to his knees, and was within easy reach of Paris when he made the peace of Crépy (1544). In Germany, meanwhile, from the diet of Augsburg (1530) onwards, he had presided at the diets or conferences, which, as he hoped, would effect the reunion of the Church.

Peace with France and the Turk and a short spell of friendliness with Pope Paul III. enabled Charles at last to devote his whole energies to the healing of religious schism. Conciliation proving impossible, he led the army which received the submission of the Lutheran States, and then captured the elector of Saxony at Muhlberg, after which the other leader, Philip of Hesse, capitulated. The Armed Diet of 1548 was the high-water mark of Charles's power. Here, in defiance of the pope, he published the Interim which was meant to reconcile the Lutherans with the Church, and the so-called Reform which was to amend its abuses. During the next four years, owing to ill-health and loss of insight, his power was ebbing. In 1552 he was flying over the Brenner from Maurice of Saxony, a princeling whose fortunes he had made. Once again the old complications had arisen. His old enemy's son, Henry II., had attacked him indirectly in Piedmont and Parma, and then directly in Germany in alliance with Maurice. Once more the Turk was moving in the Danube and in the western Mediterranean. The humiliation of his flight gave Charles new spirit, and he once more led an army through Germany against the French, only to be checked by the duke of Guise's defence of Metz. Henceforth the waves of his fortune plashed to and fro until his abdication without much ostensible loss or gain.

Charles's Policy.—Charles had abundance of good sense, but little creative genius, and he was by nature conservative. Consequently he never sought to impose any new or common principles of administration on his several States. He took them as he found them, and at most, as in the Netherlands, improved upon what he found. So also in dealing with rival powers his policy may be called opportunist. He was indeed accused by his enemies of emulating Charlemagne, of aiming at universal empire. Historians have frequently repeated this charge. Charles himself in later life laughingly denied the imputation, and facts are in favour of his denial. When Francis I. was in his power he made no attempt to dismember France, in spite of his pledges to his allies Henry VIII. and the duke of Bourbon. He did, indeed, demand the duchy of Burgundy, because he believed this to have been unrighteously stolen by Louis XI from his grandmother when a helpless girl. The claim was not pressed, and at the height of his fortunes in 1548 he advised his son never to surrender it, but also never to make it a cause of war. When Clement VII. was his prisoner he was vehemently urged to overthrow the temporal power, to restore imperial dominion in Italy, at least to make the papacy harmless for the future. In reply he restored his enemy to the whole of his dominions, even reimposing him by force on the Florentine republic. To the end of his life his conscience was sensitive as to Ferdinand's expulsion of the house of Albret from Spanish Navarre, though this was essential to the safety of Spain. Though always at war he was essentially a lover of peace, and all his wars were virtually defensive. "Not greedy of territory," wrote Marcantonio Contarini in 1536, "but most greedy of peace and quiet." For peace he made sacrifices which angered his hot-headed brother Ferdinand. He would not aid in expelling the sultan's puppet Zapolya from Ferdinand's kingdom of Hungary, and he suffered the restoration of the ruffianly duke of Württemberg, to the grave prejudice of German Catholicism. In spite of his protests, Henry VIII. with impunity ill-treated his aunt Catherine, and the feeble Government of Edward VI. bullied his cousin Mary, who had been his fiancée. No serious efforts were made to restore his brother-in-law, Christian II., to the throne of Denmark, and he advised his son Philip to make friends with the usurper. After the defeat of the Lutheran Powers in 1547 he did not gain a palm's breadth of territory for himself. He resisted Ferdinand's claim for Württemberg, which the duke had deserved to forfeit; he disliked his acceptance of the voluntary surrender of the city of Constance; he would not have it said that he had gone to war for the benefit of the house of Habsburg.

On the other hand, Charles V.'s policy was not merely negative. He enlarged upon the old Habsburg practice of marriage as a means of alliance of influence. Previously to his election as emperor, his sister Isabella was married to Christian II. of Denmark, and the marriages of Mary and Ferdinand with the king of Hungary and his sister had been arranged. Before he was 20 Charles himself had been engaged some ten times with a view to political combinations. Naturally, therefore, he regarded his near relations as diplomatic assets. The federative system was equally familiar; Germany, the Netherlands, and even Spain, were in a measure federations. Combining these two principles, he would within his more immediate spheres of influence strengthen existing federations by intermarriage, while he hoped that the same means would convert the jarring Powers of Europe into a happy family. He made it a condition of the Treaty of Madrid (1526) that Francis I. should marry his sister Eleanor, Manuel of Portugal's widow, in the hope, not that she would be an ally or a spy within the enemy's camp, but an instrument of peace. His son's marriage with Mary Tudor would not only salve the rubs with England, but give such absolute security to the Netherlands that France would shrink from war. The personal union of all the Iberian kingdoms under a single ruler had long been an aim of Spanish statecraft. So Charles had married his sister Eleanor, much against her will, to the old king Manuel, and then his sister Catherine to his successor. The empress was a Portuguese infanta, and Philip's first wife was another. It is thus small wonder that, within a quarter of a century of Charles's death, Philip became king of Portugal.

In the wars with Francis I. Italy was the stake. In spite of his success Charles for long made no direct conquests. He would convert the peninsula into a federation mainly matrimonial. Savoy, the important buffer state, was detached from France by the marriage of the somewhat feeble duke to Charles's capable and devoted sister-in-law, Beatrice of Portugal. Milan, conquered from France, was granted to Francesco Sforza, heir of the old dynasty, and even after his treason was restored to him. In the vain hope of offspring Charles sacrificed his niece, Christina of Denmark, to the valetudinarian duke. In the long negotiations for a Habsburg-Valois dynasty which followed Francesco's death, Charles was probably sincere. He insisted that his daughter or niece should marry the third rather than the second son of Francis I., in order, apart from other reasons, to run less risk of

the duchy falling under French dominion. The final investiture of Philip was forced upon him, and does not represent his saner policy. The Medici of Florence, the Gonzaga of Mantua, the papal house of Farnese, were all attached by Habsburg marriages. The republics of Genoa and Siena were drawn into the circle through the agency of their chief noble families, the Doria and Piccolomini; while Charles behaved with scrupulous moderation towards Venice in spite of her active hostility before and after the League of Cognac. Occasional acts of violence there were, such as the participation in the murder of Pierluigi Farnese, and the measures which provoked the rebellion of Siena. These were due to the difficulty of controlling the imperial agents from a distance, and in part to the faults of the victim prince and republic. On the whole, the loose federation of viceroyalties and principalities harmonized with Italian interests and traditions. The alternative was not Italian independence, but French domination. At any rate, Charles's structure was so durable that the French met with no real success in Italy until the 18th century.

Germany offered a fine field for a creative intellect, since the evils of her disintegration stood confessed. On the other hand, princes and towns were so jealous of an increase of central authority that Charles, at least until his victory over the League of Schmalkalden, had little effective power. Owing to his wars with French and Turks he was rarely in Germany, and his visits were very short. His problem was infinitely complicated by the union of Lutheranism and princely independence. He fell back on the old policy of Maximilian, and strove to create a party by personal alliances and intermarriage. In this he met with some success. The friendship of the electors of Brandenburg, whether Catholic or Protestant, was unbroken. In the war of Schmalkalden half the Protestant princes were on Charles's side or friendly neutrals. At the critical moment which preceded this, the lately rebellious duke of Cleves and the heir of Bavaria were secured through the agency of two of Ferdinand's invaluable daughters. The relations, indeed, between the two old enemies, Austria and Bavaria, were permanently improved. The elector palatine, whose love affairs with his sister Eleanor Charles as a boy had roughly broken, received in compensation a Danish niece. Her sister, widow of Francesco Sforza, was utilized to gain a hold upon the French dynasty which ruled Lorraine. More than once there were proposals for winning the hostile house of Saxony by matrimonial means. After his victory over the League of Schmalkalden, Charles perhaps had really a chance of making the imperial power a reality. But he lacked either courage or imagination, contenting himself with proposals for voluntary association on the lines of the defunct Swabian League, and dropping even these when public opinion was against them. Now, too, he made his great mistake in attempting to foist Philip upon the Empire as Ferdinand's successor. Gossip reported that Ferdinand himself was to be set aside, and careless historians have given currency to this. Such an idea was impossible. Charles wished Philip to succeed Ferdinand, while he ultimately conceded that Ferdinand's son Maximilian should follow Philip, and even in his lifetime exercise the practical power in Germany. This scheme irritated Ferdinand and his popular and ambitious son at the critical moment when it was essential that the Habsburgs should hold together against princely malcontents. Philip was imprudently introduced to Germany, which had also just received a foretaste of the unpleasant characteristics of Spanish troops. Yet the person rather than the policy was, perhaps, at fault. It was natural that the quasi-hereditary succession should revert to the elder line. France proved her recuperative power by the occupation of Savoy and of Metz, Toul and Verdun, the military keys of Lorraine. The separation of the Empire and Spain left two weakened Powers not always at accord, and neither of them permanently able to cope on equal terms with France. Nevertheless, this scheme did contribute in no small measure to the failure of Charles in Germany. The main cause was, of course, the religious schism, but his treatment of this requires separate consideration.

The characteristics of Charles's government, its mingled conservatism and adaptability, are best seen in Spain and the Netherlands, with which he was in closer personal contact than with Italy and Germany. In Spain, when once he knew the country, he never repeated the mistakes which on his first visit caused the rising of the communes. The cortes of Castile were regularly summoned, and though he would allow no encroachment on the Crown's prerogatives, he was equally scrupulous in respecting their constitutional rights. Indirectly, Crown influence increased owing to the greater control which had gradually been exercised over the composition of the municipal councils, which often returned the deputies for the cortes. Charles was throughout nervous as to the power and wealth of the greater nobles. They rather than the Crown had conquered the communes, and in the past they rather than the towns had been the enemies of monarchy. In the cortes of 1538 Charles came into collision with the nobles as a class. They usually attended only on ceremonial occasions, since they were exempted from direct taxation, which was the main function of the cortes. Now, however, they were summoned because Charles was bent upon a scheme of indirect taxation which would have affected all classes. They offered an uncompromising opposition, and Charles somewhat angrily dismissed them, nor did he ever summon them again.

Charles was well served by his ministers, whom he very rarely changed. After the death of the Piedmontese Gattinara he relied mainly on Nicolas Perrenot de Granvella for Netherland and German affairs, and on Francisco de los Cobos for Spanish, while the younger Granvella was being trained. From 1520–55 these were the only ministers of high importance. Above all, Charles never had a court favourite, and the only women who exercised any influence were his natural advisers, his wife, his aunt Margaret and his sister Mary. In all these ladies he was peculiarly fortunate.

The reign of Charles was in America the age of conquest and organization. Upon his accession the settlements upon the mainland were insignificant; by 1556 conquest was practically complete, and civil and ecclesiastical government firmly established. Actual expansion was the work of great adventurers starting on their own impulse from the older colonies. To Charles fell the task of encouraging such ventures, of controlling the conquerors, of settling the relations between colonists and natives, which involved those between the colonists and the missionary colonial Church. He must arrest de-population, provide for the labour market, regulate oceanic trade, and check military preponderance by civil and ecclesiastical organization. In America Charles took an unceasing interest; he had a boundless belief in its possibilities, and a determination to safeguard the interests of the Crown. Cortes, Pedro de Alvarado and the brothers Pizarro were brought into close personal communication with him. If he bestowed on Cortes the confidence which the loyal conqueror deserved, he showed the sternest determination in crushing the rebellious and autonomous instincts of Almagro and the Pizarros. But for this, Peru and Chile must have become independent almost as soon as they were conquered. Throughout he strove to protect the natives, to prevent actual slavery, and the consequent raids upon the natives. If in many respects he failed, yet the organization of Spanish America and the survival of the native races were perhaps the most permanent results of his reign. It is a proof of the complexity of his interests that the march of the Turk upon Vienna and of the French on Naples delayed until the following reign the foundation of Spain's eastern empire. Charles carefully organized the expedition of Magellan, which sailed for the Moluccas and discovered the Philippines. Unfortunately, his straits for money in 1529 compelled him to mortgage to Portugal his disputed claim to the Moluccas, and the Philippines consequently dropped out of sight.

If in the administration of Spain Charles did little more than mark time, in the Netherlands advance was rapid. Of the seven northern provinces he added five, containing more than half the area of the later United Provinces. In the south he freed Flanders and Artois from French suzerainty, annexed Tournai and Cambrai, and closed the natural line of French advance through the great bishopric of Liège by a line of fortresses across its western frontier. Much was done to convert the aggregate of jar-

ring provinces into a harmonious unity by means of common principles of law and finance, and by the creation of a national army. While every province had its own assembly, there were at Charles's accession only the rudiments of estates-general for the Netherlands at large. At the close of the reign the common parliamentary system was in full swing, and was fast converting the loosely knit provinces into a State.

In the Netherlands Charles showed none of the jealousy with which he regarded the Spanish nobles. He encouraged the growth of large estates through primogeniture; he gave the nobles the provincial governorships, the great court offices, the command of the professional cavalry. In the Order of the Golden Fleece and the long established presence of the court at Brussels, he possessed advantages which he lacked in Spain. The nobility were utilized as a link between the court and the provinces. Very different was it with the Church. By far the greater part of the Netherlands fell under foreign sees, which were peculiarly liable to papal exactions and to the intrigues of rival Powers. Thus the usual conflict between civil and ecclesiastical jurisdiction was peculiarly acute. To remedy this dualism of authority and the consequent moral and religious abuses, Charles early designed the creation of a national diocesan system, and this was a cherished project throughout his life. The papacy unfortunately thwarted him, and the scheme, which under Charles would have been carried with national assent and created a national Church-system, took the appearance under Philip of alien domination. If in Germany Charles was emperor, he was in the Netherlands territorial prince, and thus his interests might easily be at disaccord with those of the Empire. Consequently, just as he had shaken off French suzerainty from Flanders and Artois, so he loosened the tie of the other provinces to Germany. In 1548 they were declared free and sovereign principalities not subject to imperial laws, and all the territories were incorporated in the Burgundian circle. It was, indeed, agreed that they should contribute to imperial taxation, and in return receive imperial protection. But this soon became a dead letter, and the Netherlands were really severed from the Empire, save for the nominal feudal tie in the case of some provinces.

Charles's Religious Aims.—Charles V. is, in the eyes of many, the very picture of a Catholic zealot. Popular opinion is probably based in the main upon the letters written from Yuste in 1558, when two hot-beds of heresy had been discovered in Spain herself, and on the contemporary codicil to his will. Charles was not then the responsible authority. There is a long step between a violent letter and a violent act. Few men would care to have their lives judged by letters written in the last extremities of gout. Less pardonable was the earlier persecution of the Valencian Moriscoes in 1525–26. The edict of persecution was cruel and unnecessary, and all expert opinion in Valencia was against it. It was not, however, actually enforced until after the victory of Pavia. It seems likely that Charles in a fit of religious exaltation regarded the persecution as a sacrificial thank-offering for his miraculous preservation. Henceforth the reign was marked by extreme leniency. Spain enjoyed a long lull in the activity of her Inquisition. At Naples in 1547 a rumour that the Spanish Inquisition was to be introduced to check the growth of heresy in influential quarters produced a dangerous revolt. The briefs were, however, issued by Paul III., no friend of Charles, and when a Neapolitan deputation visited the emperor he disclaimed any intention of making innovations. Of a different type to all the above was the persecution in the Netherlands. Here it was deliberate, chronic, and on an ascending scale. In the Netherlands the heretics were his immediate subjects, and as in every other State, Catholic or Lutheran, they must conform to their prince's religion. But there was more than this. After the suppression of the German peasant revolt in 1525 many of the refugees found shelter in the teeming Netherland cities, and heresy took the form, not of Lutheranism, but of Anabaptism, which was believed to be perilous to society and the State. The Government put down Anabaptism, as a modern Government might stamp out anarchism. The edicts were, indeed, directed against heresy in general, and were as harsh as they could be—at least on paper. Yet when Charles was assured that they were embarrassing foreign trade he let it be understood that they should not affect the foreign mercantile communities. Prudential considerations proved frequently a drag upon religious zeal.

The relations of Charles to heresy must be judged in the main by his treatment of German Lutheranism. Here he had to deal with organized Churches protected by their princes, supported by revenues filched from his own Church and stiffened by formulae as rigid as those of Catholicism. The length and stubbornness of the conflict will serve to show that Charles's religious conservatism had a measure of elasticity, that he was not a bigot and nothing more. The two more obvious courses towards the restoration of Catholic unity were force and reconciliation, in other words, a religious war or a general council. Neither of these was a simple remedy. The latter was impossible without papal concurrence, inoperative without the assistance of the European Powers, and merely irritant without the adhesion of the Lutherans. It was most improbable that the papacy, the Powers and the Lutherans would combine in a measure so palpably advantageous to the emperor. Force was hopeless save in the absence of war with France and the Turk, and of papal hostility in Italian territorial politics. Charles must obtain subsidies from ecclesiastical sources, and the support of all German Catholics, especially of the traditional rival, Bavaria. Even so the Protestants would probably be the stronger, and therefore they must be divided by utilizing any religious split, any class distinction, any personal or traditional dislikes, or else by bribery. Force and reconciliation seeming equally difficult; could an alternative be found in toleration? The experiment might take the form either of individual toleration, or of toleration for the Lutheran States. The former would be equally objectionable to Lutheran and Catholic princes as loosening their grip upon their subjects. Territorial toleration might seem equally obnoxious to the emperor, for its recognition would strengthen the anti-imperial particularism so closely associated with Lutheranism. If Charles could find no permanent specific, he must apply a provisional palliative. It was absolutely necessary to patch, if not to cure, because Germany must be pulled together to resist French and Turks. Such palliatives were two—suspension and comprehension. Suspension deferred the execution of penalties incurred by heresy, either for a term of years, or until a council should decide. Thus it recognized the divorce of the two religions, but limited it by time. Comprehension instead of recognizing the divorce would strive to conceal the breach. It was a domestic remedy, German and national, not European and papal. To become permanent it must receive the sanction of pope and council, for the Roman emperor could not set up a Church of Germany. Yet the formula adopted might conceivably be found to fall within the four corners of the faith, and so obviate the necessity alike of force or council. Such were the conditions of the emperor's task, and such the methods which he actually pursued. He would advance now on one line, now on another, now on two or three concurrently, but he never definitely abandoned any. This fusion of obstinacy and versatility was a marked feature of his character.

Suspension was of course often accidental and involuntary. The two chief stages of Lutheran growth naturally corresponded with the periods, each of nine years, when Charles was absent. Deliberate suspension was usually a consequence of the failure of comprehension. Thus at Augsburg in 1530 the wide gulf between the Lutheran confession and the Catholic confutation led to the definite suspensive treaty granted to the Lutherans at Nuremberg (1532). Charles dared not employ the alternative of force, because he needed their aid for the Turkish war. In 1541, after a series of religious conferences, he personally presented a compromise in the so-called Book of Regensburg, which was rejected by both parties. He then proposed that the articles agreed upon should be compulsory, while on others toleration should be exercised until a national council should decide. Never before nor after did he go so far upon the path of toleration, or so nearly accept a national settlement. He was then burning to set sail for Algiers. His last formal suspensive measure was that of Spires (Speyer) in 1544, when he was marching against Francis.

He promised a free and general council to be held in Germany, and, as a preparation, a national religious congress. The Lutherans were privately assured that a measure of comprehension should be concluded with or without papal approval. Meanwhile all edicts against heresy were suspended. No wonder that Charles afterwards confessed that he could scarcely reconcile these concessions with his conscience, but he won Lutheran aid for his campaign. The peace of Crépy gave all the conditions required for the employment of force. He had peace with French and Turk, he won the active support of the pope, he had deeply divided the Lutherans and reconciled Bavaria. Finding that the Lutherans would not accept the council summoned by the pope to Trent, he resorted to force, and force succeeded. At the Armed Diet of 1548 reunion seemed within reach. But Paul III. in direct opposition to Charles's wish had withdrawn the council from Trent to Bologna. Charles could not force Lutherans to submit to a council which he did not himself recognize, and he could not bring himself to national schism. Thus, falling back upon his old palliatives, he issued the Interim and the accompanying Reform of the Clergy, pending a final settlement by a satisfactory general council. These measures pleased neither party, and Charles at the very height of his power had failed. He was conscious of failure, and made few attempts even to enforce the Interim. Henceforward political complications gathered round him anew. The only remedy was toleration in some form, independent of the papacy and limitless in time. To this Charles could never assent. His ideal was shattered, but it was a great ideal, and the patience, the moderation, even at times the adroitness with which he had striven towards it, proved him to be no bigot.

Abdication and Death.—The idea of abdication had long been present with Charles, and in 1555 he acted upon it. To Ferdinand he gave his full authority as emperor, although at his brother's earnest request formal abdication was delayed until 1558. In the Hall of the Golden Fleece at Brussels on Oct. 25, 1555, he formally resigned to Philip the sovereignty of his beloved Netherlands. Turning from his son to the representatives of the estates he said: "Gentlemen, you must not be astonished if, old and feeble as I am in all my members, and also from the love I bear you, I shed some tears." In the Netherlands at least the love was reciprocal, and tears were infectious among the thousand deputies who listened to their sovereign's last speech. On Jan. 16, 1556, Charles resigned his Spanish kingdoms and that of Sicily, and shortly afterwards his county of Burgundy. On Sept. 17 he sailed from Flushing on the last of his many voyages, an English fleet from Portland bearing him company down the channel. In Feb. 1557 he was installed in the home which he had chosen at Yuste in Estremadura.

The excellent books which have been written upon the emperor's retirement have inspired an interest out of all proportion to its real significance. His little house was attached to the monastery, but was not within it. He was neither an ascetic nor a recluse. Gastronomic indiscretions still entailed their inevitable penalties. Society was not confined to interchange of civilities with the brethren. His relations, his chief friends, his official historians, all found their way to Yuste. Couriers brought news of Philip's war and peace with Pope Paul IV., of the victories of Saint Quentin and Gravelines, of the French capture of Calais, of the danger of Oran. As head of the family he intervened in the delicate relations with the closely allied house of Portugal; he even negotiated with the house of Navarre for reparation for the wrong done by his grandfather Ferdinand, which appeared to weigh upon his conscience. Above all he was shocked by the discovery that Spain, his own court, and his very chapel were infected with heresy. His violent letters to his son and daughter recommending immediate persecution, his profession of regret at having kept his word when Luther was in his power, have weighed too heavily on his reputation. The feverish phrases of religious exaltation due to broken health and unnatural retirement cannot balance the deliberate humanity and honour of wholesome manhood. Apart from such occasional moments of excitement, the emperor's last years passed tranquilly enough. At first he would shoot pigeons in the monastery woods, and till his last illness tended his garden and his animal pets, or watched the operations of Torriani, maker of clocks and mechanical toys. After an illness of three weeks the call came in the early hours of the Feast of St. Matthew, who, as his chaplain said, had for Christ's sake forsaken wealth even as Charles had forsaken empire. The dying man clasped his wife's crucifix to his breast till his fingers lost their hold. The archbishop held it before his eyes, and with the cry of "*Ay Jesus!*" died, in the words of his faithful squire, D. Luis de Quijada, "the chief of men that had ever been or would ever be." Posterity need not agree, but no great man can boast a more honest panegyric.

In character Charles stands high among contemporary princes. It consists of pairs of contrasts, but the better side is usually stronger than the worse. Steadfast honesty of purpose was occasionally warped by self-interest, or rather he was apt to think that his own course must needs be that of righteousness. Self-control would give way, but very rarely, to squalls of passion. Obstinacy and irresolution were fairly balanced, the former generally bearing upon ends, the latter upon means. His own ideals were constant, but he could gradually assimilate the views of others, and could bend to argument and circumstance; yet even here he had a habit of harking back to earlier schemes which he had seemed to have definitely abandoned. As a soldier he must rank very high. It was said that his being emperor lost to Spain the best light horseman of her army. At every crisis he was admirably cool, setting a truly royal example to his men. His mettle was displayed when he was attacked on the burning sands of Tunis, when his troops were driven in panic from Algiers, when in spite of physical suffering he forded the Elbe at Mühlberg, and when he was bombarded by the vastly superior Lutheran artillery under the walls of Ingolstadt. When blamed for exposing himself on this last occasion, "I could not help it," he apologized; "we were short of hands, I could not set a bad example." Nevertheless he was by nature timid. Just before this very action he had a fit of trembling, and he was afraid of mice and spiders. The force of his example was not confined to the field. Melanchthon wrote from Augsburg in 1530 that he was a model of continence, temperance and moderation, that the old domestic discipline was now only preserved in the imperial household. He tenderly loved his wife, whom he had married for pecuniary and diplomatic reasons. Of his two well-known illegitimate children, Margaret was born before he married, and Don John long after his wife's death, but he felt this latter to be a child of shame. His sobriety was frequently contrasted with the universal drunkenness of the German and Flemish nobles, which he earnestly condemned. But on his appetite he could place no control, in spite of the ruinous effects of his gluttony upon his health. In dress, in his household, and in his stable he was simple and economical. He loved children, flowers, animals and birds. Professional jesters amused him, and he was not above a joke himself. Maps and mechanical inventions greatly interested him, and in later life he became fond of reading. He takes his place indeed among authors, for he dictated the commentaries on his own career. Of music he possessed a really fine knowledge, and his high appreciation of Titian proves the purity of his feeling for art. The little collection of books and pictures which he carried to Yuste is an index of his tastes. Charles was undeniably plain. He confessed that he was by nature ugly, but that as artists usually painted him uglier than he was strangers on seeing him were agreeably disappointed. The protruding lower jaw and the thin pale face were redeemed by the fine open brow and the bright speaking eyes. He was, moreover, well made, and in youth had an incomparable leg. Above all no man could doubt his dignity; Charles was every inch an emperor. (E. Ar.)

Rosi, *Il Primato di Carlo V.* (1925).

CHARLES VI. (1685–1740), Roman emperor, was born on Oct. 1, 1685, at Vienna. He was the second son of the emperor Leopold I. by his third marriage with Eleanore, daughter of Philip William of Neuburg, elector palatine of the Rhine. When the Spanish branch of the house of Habsburg became extinct in 1700, he was put forward as the lawful heir in opposition to Philip V., the Bourbon to whom the Spanish dominions had been left by the will of Charles II. of Spain. He was proclaimed at Vienna on Sept. 19, 1703, and made his way to Spain by the Low Countries, England and Lisbon, remaining in Spain till 1711, mostly in Catalonia, where the Habsburg party was strong. Although he had a certain tenacity of purpose he displayed none of the qualities required in a prince who had to gain his throne by the sword (*See* SPANISH SUCCESSION, WAR OF). In 1708 he was married at Barcelona to Elizabeth Christina of Brunswick-Wolfenbüttel (1691–1750), a Lutheran princess who was persuaded to accept Roman Catholicism. On the death of his elder brother Joseph I. on April 17, 1711, Charles inherited the hereditary possessions of the house of Habsburg and their claims on the Empire. The death of Joseph without male issue had been foreseen, and Charles had at one time been prepared to give up Spain and the Indies on condition that he was allowed to retain Naples, Sicily and the Milanese. But when the case arose his natural obstinacy led him to declare that he would not think of surrendering any of the rights of his family. It was with great difficulty that he was persuaded to leave Spain, months after the death of his brother (on Sept. 27, 1711). Only the emphatic refusal of the European powers to tolerate the reconstruction of the empire of Charles V. forced him to give a sullen submission to necessity. He abandoned Spain and was crowned emperor in December 1711, but for a long time he would not recognize Philip V. Charles showed an enlightened, though not always successful, interest in the commercial prosperity of his subjects, but from the date of his return to Germany till his death his ruling passion was to secure his inheritance against dismemberment. As early as 1713 he had begun to prepare the "Pragmatic Sanction" which was to regulate the succession, and it became the object of his policy to obtain the recognition of his daughter Maria Theresa as his heiress. His last days were embittered by a disastrous war with Turkey, in which he lost almost all he had gained by the peace of Passarowitz. He died at Vienna on Oct. 20, 1740, and with him expired the male line of his house.

For the personal character of Charles VI. *see* A. von Arneth, *Geschichte Maria Theresias* (Vienna, 1863–79). Dr. Franz Krones, R. v. Marchland, *Grundriss der österreichischen Geschichte* (Vienna, 1882), gives a very copious bibliography. *See* also J. Ziekursch, *Die Kaiserwahl Karls VI.* (1902).

CHARLES VII. (1697–1745), Roman emperor, known also as Charles Albert, elector of Bavaria, was the son of the elector Maximilian Emanuel and his second wife, Theresa Cunigunda, daughter of John Sobieski, king of Poland. He was born on Aug. 6, 1697. His father having taken the side of Louis XIV. of France in the War of the Spanish Succession (*q.v.*), Bavaria was occupied by the allies. Charles and his brother Clement, afterwards archbishop of Cologne, were carried prisoners to Vienna, and were educated by the Jesuits under the name of the counts of Wittelsbach. When his father was restored to his electorate Charles was released, and in 1717 he led the Bavarian contingent of the imperial army which served under Prince Eugene against the Turks, and is said to have distinguished himself at Belgrade. On Sept. 25, 1722, he was betrothed to Maria Amelia, the younger of the two orphan daughters of the emperor Joseph I. Her uncle Charles VI. insisted that the Bavarian house should recognize the Pragmatic Sanction which established his daughter Maria Theresa as heiress of the Habsburg dominions. They did so, but with secret protests and mental reservations of their rights, which were designed to render the recognition valueless. The electors of Bavaria had claims on the possessions of the Habsburgs under the will of the emperor Ferdinand I., who died in 1564.

Charles succeeded his father on Feb. 26, 1726. His policy was to keep on good terms with the emperor while slipping out of his obligation to accept the Pragmatic Sanction and intriguing to secure French support for his claims whenever Charles VI. should die. These claims were advanced immediately after the death of Charles VI. on Oct. 20, 1740. Charles Albert now entered into the league against Maria Theresa, to the great misfortune of himself and his subjects. By the help of her enemies he was elected emperor in opposition to her husband Francis, grand duke of Tuscany, on Jan. 24, 1742, under the title of Charles VII. and was crowned at Frankfurt-am-Main on Feb. 12. But as his army had been neglected, he was utterly unable to resist the Austrian troops. While he was being crowned his hereditary dominions in Bavaria were being overrun. During the War of the Austrian Succession (*q.v.*) he was a mere puppet in the hands of the anti-Austrian coalition, and was often in want of mere necessities. In the changes of the war he was able to re-enter his capital, Munich, in 1743, but had immediately afterwards to take flight again. He was restored by Frederick the Great in Oct. 1744, but died worn out at Munich on Jan. 20, 1745.

See A. von Arneth, *Geschichte Maria Theresias* (Vienna, 1863–79), and P. T. Heigel, *Der österreichische Erbfolgestreit und die Kaiserwahl Karls VII.* (Munich, 1877).

CHARLES I. (1887–1922), emperor of Austria and king of Hungary, born Aug. 17, 1887, in Persenbeug, in Lower Austria, was the son of the archduke Otto (1865–1906), and Princess Maria Josepha of Saxony (1867–1944). The death of his father in 1906 and the renunciation by his uncle, the archduke Francis Ferdinand, on his marriage with the countess Chotek (1900) of any right of succession for the children of this union, made him heir-presumptive to his great-uncle, the emperor, Francis Joseph. In Oct. 1911 he married the princess Zita of Bourbon-Parma. Of this marriage there were several sons and daughters, the eldest of whom, Otto, was born in 1912. Charles' relations with the emperor were not intimate, and those with Francis Ferdinand not cordial. After the death of Francis Ferdinand the old emperor took steps to initiate him in affairs of State; but these studies were interrupted almost immediately by the outbreak of the World War. After a period at headquarters at Teschen, Charles commanded the 20th Corps in the offensive of 1916 against Italy, later commanding an army on the eastern front.

Charles as Emperor.—On Nov. 21, 1916, he succeeded to the throne, at a period of extreme difficulty, which he hoped to meet by making a complete change in the leading military and political posts in the monarchy. The changes, however, usually proved unfortunate. Charles himself was an amiable man of excellent intentions, but his abilities were mediocre and his preparatory training inadequate. He lacked calmness and endurance, and was prone to headlong, precipitate actions. He was powerfully influenced by his immediate entourage—his wife and mother-in-law—while distrusting all other advisers. But he was most bitterly—and justly—reproached for insincerity. Not merely his enemies, but his allies, particularly German statesmen and the emperor William, soon felt that they could not trust his word; a sentiment shared by the peoples of the Danubian monarchy.

On Charles' accession the Constitution in Austria was still suspended. In May 1917 he summoned parliament once more, but the concessions Charles now made to the Slavonic nationalities remained fruitless, merely alienating the majority of the German Austrians, while his concessions to the Magyars in Hungary similarly irritated the conservatives of Vienna and the non-Magyars of Hungary, without checking the separatist movement. He was equally unfortunate in his peace proposals. While refusing the idea of a separate peace for Austria, he endeavoured to persuade

termined to summon a parliament in England to gain supplies to renew the war against the Scots. When the Short parliament met in April 1640 members were asked to proceed immediately to pass a money bill but John Pym, who now led the opposition to the king, spoke of grievances. When the king professed that after money had been granted he would be willing to consider complaints, the commons fixed a day to debate troubles in Scotland. Thereupon Charles once again dissolved parliament. He committed one of the greatest blunders of his reign because this parliament would probably have been content with moderate, not revolutionary, changes in the government. He was equally at fault in promulgating the canons of 1640 which contained among other articles obnoxious to Puritans, the command to every minister to read each quarter a statement that kings were of divine origin and given by God a supreme power over all persons, and that to bear arms against the king was to resist power ordained of God and so incur damnation. Charles soon discovered that his subjects did not accept this definition of their duties. To punish the Scots, he now called upon the militia of the southern counties but the only time they encountered the Scots they gave way to disgraceful panic, leaving Northumberland and Durham open to their enemies. Charles was constrained to open negotiations but found the Scots would agree to an armistice only on condition that they should continue to occupy the north counties and be paid £850 a day. They were looking forward to a settlement with an English parliament rather than with the king. Charles had no option but to summon a parliament. Unless it met and granted supplies his forces in Yorkshire would disband and the Scottish army could march unopposed to London, where it was likely to be welcomed. Thus when it met on Nov. 3, 1640 the Long parliament had in effect an army in its pay, a situation lasting until the following August when the treaty with the Scots was completed. Thus the king dared not dismiss this parliament as he had four others. Charles had so few supporters that he could not save his advisers from imprisonment or exile, or, in the case of the earl of Strafford (the former Wentworth), execution. He promised Strafford three weeks before the end that he should not suffer in life, honour or fortune. But the royal intervention did more harm than good and an obscure army plot which included an attempt to put the Tower of London into loyal hands was fatal. Charles, feeling that his wife's life was not safe from the armed mob that surrounded the palace shouting for justice, gave way. Strafford had urged the king not to let him be a hindrance to reconciliation between king and parliament. When he heard that the Bill of Attainder had been signed he is said to have exclaimed, "put not your trust in princes." Charles regretted his consent all his life and regarded his own death as an expiation for the sacrifice of his faithful servant. He is not known to have expressed any sorrow that he was largely responsible for the general apprehension that Strafford was too dangerous a man to let live.

During the first year of the Long parliament the king could not oppose measures to abolish prerogative courts like the Star Chamber and High commission and declare unlawful the financial expedients used during the 1630s. He even consented to acts to ensure that parliament meet every third year and that it could not be dissolved without its own consent. Pym and his adherents had established the reign of law so far as statutes could achieve it. They had effectively curbed the royal power but had not provided a substitute to rule the country. The constitution in 1641 may be likened to an old locomotive which parliament had equipped with powerful brakes but left the engine unrepaired.

In Aug. 1641 Charles paid a second visit to Scotland. His gracious reception induced the belief that the Scots would maintain and place at his command some of the army now returning from north England. He also thought that he could bribe his bitterest opponents by promises of preferment to office and promotions in the peerage. He was disappointed in both respects. The Scottish army was disbanded, and the earl of Argyll, though created a marquis, and other covenanting leaders could not be bought. Instead, they insisted that officers of state must be acceptable to parliament. While the king was failing to form a Scottish party to intervene in England he was ordering his agents in Ireland to try to secure the support of Irish Catholics by vague offers of toleration. It was highly improbable that Charles ever seriously pondered the question whether Scottish Presbyterians and Irish Catholics could be combined to coerce his English subjects. That he never seemed to have considered his policy in all its bearings was a permanent weakness. Instead he passed from one intrigue to another without seeing that the ultimate result would be general distrust. During his absence from London parliament passed the first of the many ordinances it was to issue without the royal assent hitherto regarded as essential to give a bill the force of law.

When after a month's recess the Long parliament reopened in Oct. 1641 the king was in a stronger position. He had taken into his councils Edward Hyde, later earl of Clarendon, who formed a party of constitutional royalists. The text for the many state papers he wrote for the king he borrowed from a speech of Pym's, "the law is that which puts the difference betwixt good and evil, betwixt justice and injustice." He sought to prove that the king was now the guardian of the constitution against the innovations of parliamentary leaders animated by selfish ambition. He urged the king to take his stand on the known laws of the land and await a reaction in his favour. The opponents of episcopacy at first demanded the punishment of obnoxious bishops like Laud but were now demanding the abolition of the order. This assault was likely to rally many defenders and split assailants who were not agreed on what to substitute for the Anglican church. The king unfortunately for himself lacked the firmness and patience to follow Hyde's policy for long. He was always intriguing to regain the powers he had surrendered.

Towards the end of 1641 two events of great significance to Charles I occurred: the Irish Rebellion and the passage of the Grand Remonstrance. On Oct. 23 the native Irish with some Anglo-Irish Catholics rose against the English and Scots who had dispossessed them of their land and outlawed their religion. They slaughtered several thousand Protestants. Very exaggerated news of the massacre reached England and Charles's opponents depicted the dangers to Protestants in the most lurid colours. The need for an army to put down the rebellion raised the question whether king or parliament should control it. The commons required that the king should employ only ministers approved by parliament, otherwise they would entrust the reconquest of Ireland to those in whom they had confidence. This was the most revolutionary step hitherto taken. At the same time the commons debated the Grand Remonstrance, which was an appeal to the country in the form of a partisan statement of the grievances already redressed and of the evils still to be cured. Its passage by 11 votes only showed that nearly half the commons were now royalists. Once again Charles threw away his chances. His attempt to arrest the five members in the house of commons (Jan. 4, 1642) lost him most of the ground he had regained. Had the parliamentarians shown moderation during the next six months the king must have submitted to their demands, but their Nineteen Propositions (June 2) sought to reduce him to a mere titular sovereign and left the church to be reformed by the Puritans. They voted that the cost of raising an army should be borne by malignants or those who had not actively assisted the parliament. The result was that many in this vague category who might otherwise have remained neutral took up arms for the king.

The civil wars are described under the separate article GREAT REBELLION and are here included only for the king's actions. He proved himself a good strategist but a poor tactician. He realized that London was the heart of the parliamentary cause but was unable to co-ordinate his different armies to attack it. However, the material resources at parliament's command were much superior to his especially after the Solemn League and Covenant (Sept. 1643) had brought a Scottish army into England. The new model army formed early in 1645 ended the first civil war in a year. During and after the war various negotiations between king and parliament produced no results. The king could never put himself in the position of a national leader. All concessions he regarded as temporary, wrested from him by rebels. He told his wife in 1646 with reference to the establishment of Presbyterianism for three years that he did so in order to "lay a ground for a

perfect recovery of that (the Anglican church), which, to abandon, were directly against my conscience, and, I am confident, destructive to monarchy." Unfortunately for his reputation his conscience did not prevent his returning evasive, his enemies thought deceitful, answers to all overtures for peace. He fancied that sooner or later quarrels between parliament, the army and the Scots would make him arbitrator of their differences. Therefore, he tried to spin out time until his enemies were at each others' throats, but he exhausted their patience so that the Scots to whom he had delivered himself in May 1646 surrendered him to the English parliament in January. In June 1647 Cornet Joyce under Oliver Cromwell's orders carried off the king and brought him into the army's custody. Charles escaped to the Isle of Wight and in Dec. 1647 signed with the Scottish commissioners the Engagement for the establishment of Presbyterianism for three years and the suppression of the sectaries. Thus the union between Presbyterians and royalists was formed which was ultimately to lead to the Restoration. Its immediate results were the victory of the army over its enemies and its determination to bring the king to trial. After some 140 M.P.'s had been expelled from parliament by Pride's purge (Dec. 1648), the remnant appointed commissioners to form a court. The king declined to acknowledge its authority, whereupon the sentence was passed that he should be beheaded as a tyrant and public enemy to his people. On the scaffold (Jan. 30, 1649) he submitted to his fate with a quiet dignity. He said that he "did not believe the happiness of people lay in sharing government, subject and sovereign being clean different." This persistent denial of a subject's constitutional rights was a main cause of his failure. His support of the Anglican church probably commended itself to the majority of Englishmen though they disliked the Laudian principles so dear to the king.

Charles's private life was most exemplary. He was an affectionate husband and father, devout in his religion and regular in his habits. He looked every inch a king. He had a genuine interest in painting, especially of the Italian school, and so far as his limited resources allowed was a great collector and patron of the arts. Immediately after his death appeared *Eikon Basilike* which was thought to be at the time the king's own account of his sufferings, though it is now known to have been written by John Gauden, perhaps after consultation with the king or examination of some of his papers. It earned for him his reputation as a martyred king.

He was survived by his wife (*see* HENRIETTA MARIA), his sons Charles, James (*see* CHARLES II and JAMES II), and Henry, duke of Gloucester (1639–60), and his daughters Mary (1631–60), who married William II of Orange, Elizabeth (1635–50), and Henrietta (1644–70) who married Philip, duke of Orleans.

BIBLIOGRAPHY.—The public life of Charles I is part of the history of Great Britain and sources and later works for it can be found in *Bibliography of British History, Stuart Period, 1603–1714*, ed., G. Davies (Oxford, 1928) or in the bibliographies appended to such histories as G. M. Trevelyan, *England under the Stuarts* (New York, 1904); F. C. Montague, *The History of England From the Accession of James I to the Restoration, 1603–1660* (New York, 1907); G. Davies, *The Early Stuarts, 1603–1660* (Oxford, 1937). Two works by S. R. Gardiner are indispensable: *History of England*, 10 vol. (1884) and *Great Civil War, 1642–1649*, 4 vol. (New York, 1893). The proclamations, declarations, etc., issued by the king or in his name can be found in many collections such as *Reliquiae sacrae Carolinae* (1649), *Basilika: The Works of King Charles* (1662) or *Letters, Speeches, and Proclamations of King Charles I*, ed., Sir Charles Petrie (London, 1935). Those written by Edward Hyde (later Earl of Clarendon) are printed in his *History of the Great Rebellion*, 6 vol. (Oxford, 1888), which, together with his *Life*, 2 vol. (1857), has interesting comments on the king and his policy. The king's private correspondence is not large, but his character is well illustrated in *Charles I in 1646: Letters of King Charles the First*, ed., John Bruce, (1856). The best biographies are by F. M. G. Higham, *Charles I* (London, 1932) and E. C. Wingfield-Stratford, *Charles King of England 1600–1637* (London, 1949), *King Charles and King Pym 1637–1643*, (London, 1949) and *King Charles the Martyr 1643–1649* (London, 1950). Sir John Skelton, *Charles I* (1898) has many illustrations. Studies of special topics include J. G. Muddiman, *The Trial of King Charles the First* (1928), Gordon Albion, *Charles I and the Court of Rome* (Louvrain, Belg.; London, 1935), G. M. Young, *Charles I and Cromwell* (London, 1935); H. P. Cooke, *Charles I and His Earlier Parliaments* (London, 1939), and F. F. Madan, ed., *A New Bibliography of the Eikon Basilike of King Charles the First* (London, 1950). For Charles as a patron of art and a collector *see* Francis Henry Taylor, *The Taste of Angels* (Boston; Toronto, 1948), and *The Burlington Magazine*, Jan. 1949. (G. Ds.)

CHARLES II (1630–1685), king of Great Britain and Ireland, 2nd son of Charles I and Henrietta Maria, was born on May 29, 1630. In 1638 the duke of Newcastle was appointed as his governor, but his education was interrupted by the Civil War. In 1645 Charles I sent him into the west of England, where his council included, among others, Sir Edward Hyde. In March 1646 the royalist defeats drove him to the Scilly Isles and later to Jersey, and in July he joined his mother in Paris. He remained there under her control for two years, and continued his studies, Thomas Hobbes being his tutor for mathematics.

In 1648 Charles cruised with some English ships off the mouth of the Thames, but effected nothing and retired to Holland. In Jan. 1649 he sent a blank sheet of paper, bearing his signature, to parliament, for the insertion of any terms which would save his father's life. After Charles I's execution on Jan. 30, 1649, he was proclaimed king in Scotland and parts of Ireland and in the Channel Islands. He went to Jersey in September, but was obliged to retire to Breda (Feb. 1650), and from that place he came to terms with the Scots, accepting the Covenant and abandoning the earl of Montrose, whom he had encouraged to attempt another royalist rising in Scotland. He landed in Scotland on June 23, 1650, after pledging himself to Presbyterianism in both Scotland and England. An attempt to escape from the Covenanters, known as "the Start," failed, and on Jan. 1, 1651, Charles was crowned as king of Scots at Scone. Oliver Cromwell's advance forced him to march into England and on Sept. 3 Cromwell defeated him at Worcester. Charles showed great courage in the battle, and after an amazing series of adventures, including his concealment in the "royal oak" at Boscobel, sailed from Brighton for France on Oct. 15.

His advisers were henceforward the royalists, Hyde, duke of Ormonde, and, from 1654, Sir Edward Nicholas. Plots for risings in England and Scotland and for Cromwell's assassination failed. In 1654 Cromwell's negotiations with France drove Charles to Germany, but after Cromwell's alliance with France he made a treaty with Spain (April 1656) and resided at Bruges or Brussels. His chief source of income was a Spanish pension; and he was very poor. Cromwell's death did not immediately alter his position and in 1659 he went to Fuenterrabia, where the peace of the Pyrenees was being negotiated between France and Spain, to ask for military aid. This journey and a royalist rising in England just before it were alike fruitless.

Events in England brought about the Restoration, which the royalists alone could not have accomplished. By the end of 1659 a return to the old constitution was the only escape from the alternatives of military government or anarchy. George Monck (duke of Albemarle) advanced with an armed force from Scotland; by recalling the secluded members of the Long parliament, power was transferred from the Independents to the Presbyterians. A "free" parliament was summoned to meet in April 1660 while Monck opened negotiations with Charles, who, following his advice, issued the Declaration of Breda April 4. Largely the work of Hyde, it promised a general amnesty and liberty of conscience and to the army full arrears of pay, leaving the final settlement in each case to parliament; it also promised that all questions about the transfers of lands during the past years of revolutions should be determined in parliament. The Convention parliament, in which the secular peers again sat, accepted the declaration and Charles was proclaimed king on May 8. On May 25 he landed at Dover, where he was met by Monck, and on May 29, amid universal rejoicing, arrived at Whitehall.

The agreement of Charles and Monck in leaving the settlement to parliament meant that the Restoration was a restoration of parliamentary government, not of personal monarchy. Charles was not a conqueror and had no armed force of his own, while during the last 20 years almost all classes in England had acquired a permanent interest in politics. The administration could not be carried on without the help of men who had already been employed by the revolutionary governments and the new council included

faithful royalists and former rebels.

The willing co-operation of the Convention and the unbounded loyalty of its successor in its earlier years encouraged Charles to entrust many matters to parliament. The Restoration dissolved the legislative union with Scotland and Ireland, and led to the re-establishment of their separate parliaments. In Scotland the return of the old order was complete, and brought back episcopacy and repression; in Ireland the Cromwellian settlement was firmly established and was upheld by English opinion.

Hyde, created earl of Clarendon, was still Charles's chief adviser, and directed the work of reconstruction in England. All the acts of the revolutionary governments since 1642 were held to be invalid; judicial proceedings since that date were confirmed by a special act. The Navigation act of 1651 was re-enacted; the abolition of feudal incidents (the abolition of tenure by knight service, of the feudal dues attaching to it, and of the court of wards and its local agents which dealt with them) completed in 1646, was maintained by a new act. The Indemnity bill led to disputes between Charles and parliament, Charles desiring lenity. Thirteen regicides and young Sir Henry Vane were executed; 25 regicides, John Lambert and Sir Arthur Hesilrige were imprisoned for life; otherwise the amnesty was complete. Crown and church lands, and other lands sequestered by the revolutionary governments, reverted to their former owners, but royalists who had sold part of their lands to meet the fines inflicted on them received no compensation. By means of special taxes the army was paid off by Feb. 1661 though, as a result of the alarm caused by Thomas Venner's rising, Charles was able to retain Monck's regiment of infantry, known henceforward as the Coldstream guards, and a cavalry regiment, the Blues. By 1685, mainly by the return of regiments from Dunkirk and Tangier, this force was increased by five regiments of foot and one of dragoons. The government's income was fixed at £1,200,000, but the sources allocated did not produce that amount, and the government was involved from the start in pecuniary difficulties for which it was not responsible.

The restoration of the church was slower. Charles was pledged to toleration, and plans for comprehension were put forward. The Convention was dissolved in Dec. 1660 without settling anything, and the Savoy conference between Anglicans and Presbyterians, proved sterile. Charles was crowned on April 23, 1661, and a new parliament met on May 8; as it sat until 1679 it is called the Long Parliament of the Restoration, and sometimes the Cavalier or the Pensionary parliament. It contained at the start, and until by-elections gradually changed its character, an overwhelming royalist and Anglican majority, and Charles and the earl of Clarendon could not restrain it on religious questions. The bishops returned to the upper house on Nov. 20, 1661. On May 19, 1662, the Act of Uniformity was passed, enjoining the use of the Book of Common Prayer, which had been specially revised, and included new services of Jan. 30 and May 29 (the dates of the execution of Charles I and the Restoration); as a result about 1,200 of the clergy, who refused to conform, left their livings on St. Bartholomew's day (Aug. 24); another 800 had already been ejected. The Presbyterians had hitherto tried to gain control of the national church while remaining within it. Now those among them who did not conform were driven to take up a position definitely outside it and, together with the various independent sects, came to be known as Nonconformists or Dissenters. Charles tried to relieve them and the Roman Catholics by a declaration of indulgence issued on Dec. 26, 1662, but it was opposed by Clarendon and by parliament; and a series of acts was passed, including the Conventicle and Five Mile acts, forbidding the Nonconformists their special forms of worship; it is unjustly called the Clarendon code. The Corporation act (1661) drove the Nonconformists from power in the boroughs; the Licensing act (1662), establishing a censorship, and the repeal of the 1641 Triennial act and the passing of a new act, requiring triennial parliaments but providing no machinery for enforcing this requirement if the king failed to observe it, completed the reconstruction of the constitution.

Charles's foreign policy was largely a continuation of Cromwell's, although based on material rather than on religious considerations. Peace was made with Spain, but Jamaica and Dunkirk were retained, and Charles, when he married the Portuguese Catherine of Braganza in 1662, pledged himself to give Portugal military support in its struggle with Spain. The marriage, which brought Bombay and Tangier to England as parts of Catherine's dowry, drew England closer to France; the two countries were further connected by the marriage of Charles's sister, Henrietta Anne, to the duke of Orleans and by the sale of Dunkirk to France. Dunkirk was a costly possession and Charles had neither the money nor the troops to hold it effectively. In 1664 English commercial expansion and minor political differences led to war with the Dutch, formally declared in Feb. 1665. The struggle was indecisive, but England was weakened by the Great Plague in 1665, and the Fire of London in 1666. Financial exhaustion led to negotiations, and in 1667 the Dutch, by burning the English ships in the Medway, enforced the conclusion of the peace of Breda. Both sides kept their conquests, England obtaining New York and New Jersey. Parliament demanded a sacrifice and attacked Clarendon. Charles was annoyed by his opposition to toleration and tired of his lectures on his private misconduct; to the delight of the courtiers and the younger politicians he allowed him to be exiled.

Free from tutelage, Charles determined to follow his own policy. He was very short of money, disliked parliamentary control and believed that he could escape from his difficulties by an alliance with the Catholics and the Dissenters at home and the French abroad; his desire for toleration and his personal inclination toward Catholicism, increased by his knowledge of the attitude of his brother James, duke of York, alike recommended this policy. He also wanted to revenge himself on the Dutch for his humiliation at Chatham. Henceforward he never gave complete confidence to any minister. He now employed Sir Thomas Clifford and the earl of Arlington but allowed the duke of Buckingham some show of power. These three with Lord Ashley and the earl of Lauderdale, formed the notorious Cabal, so-called because the first letters of their names formed that word. It was not a ministry in the modern sense, there being no common policy or joint responsibility. Charles hoped to attain his ends by the support of Louis XIV who, engaged in promoting his queen's claims to the Spanish succession, was prepared to buy the alliance or the neutrality of England.

The Triple Alliance, formed in 1668 between England, Holland and Sweden, appeared for a time to threaten Louis's projects. It was extremely popular in England, but Charles excused his share in it to Louis, whom it infuriated against the Dutch. In 1669 Charles declared to the French ambassador his desire to be reconciled to Rome, and through the duchess of Orleans negotiated with Louis the secret treaty of Dover, signed on May 22, 1670. Charles was to declare himself a Catholic when the time seemed ripe, in view of possible disturbances Louis was to pay him rather more than £150,000 and to provide 6,000 men; thereafter France and England were to join in a war against the Dutch. (*See* Dover, Treaty of.) Only Clifford and Arlington among the ministers signed this treaty; in Dec. 1670 the whole Cabal signed a feigned treaty, which omitted the conversion clauses. Charles was easily led to postpone them; what importance he attached to them cannot be determined. In 1671 Louis sent Louise de Kérouallé, later duchess of Portsmouth, to England to become Charles's mistress.

The war against the Dutch began in 1672; at the same time, to win support, Charles issued the Declaration of Indulgence, suspending the penal laws, and postponed all payments of assignations on the revenue; this was the "Stop of the Exchequer," affecting the London bankers. The war, although it established British commercial and naval supremacy, was unpopular. In 1673 parliament forced Charles to cancel the Declaration of Indulgence and to pass the Test act, which drove Catholics, including Clifford and James, from office. In 1674 Charles was obliged to make peace with the Dutch.

The earl of Danby (Sir Thomas Osborne, later duke of Leeds) succeeded the Cabal. His policy, based on the alliance of church and crown, was calculated to detach from the opposition the loyalists driven to it by hatred of the Cabal; by patronage and corruption he increased their number and formed a strong "Court party"

in parliament. Ashley, now earl of Shaftesbury, led the opposition "Country party" to which the by-elections furnished recruits. It was generally predominant, but French subsidies enabled Charles to resist it. Danby was obliged to concur in this, but tried to direct foreign policy along more popular lines, and in Nov. 1677 brought about the marriage of James's daughter, Mary, with William of Orange (afterward William III and Mary II). Charles turned against Louis who, not without bribery, persuaded the Country party to refuse supplies for the army and then made the Peace of Nijmegen with the Dutch.

Hatred of the Cabal and distrust of Charles had prepared the way for Titus Oates, who, in Aug. 1678 denounced an intended rising of the Catholics. This, the "popish plot," was almost entirely fictitious, as Charles readily discovered, but it received apparent confirmation from Edward Coleman's letters and the death of Sir Edmund Berry Godfrey (*q.v.*). Shaftesbury promoted the ensuing general panic. Charles let the agitation take its course, intervening only when Oates accused the queen; between 1678 and 1681 some 35 victims were executed, although Charles knew most of them to be innocent of the charges brought against them. He now realized the importance of the unhesitating support of the church. He dissolved parliament in Jan. 1679 to save Danby from impeachment, after the revelation by Montague of that minister's acquiescence in the financial dealings with Louis XIV. The Licensing act lapsed immediately, resulting in a flood of pamphlets and newspapers. James was sent abroad; an experimental reform of the council failed; the new parliament had to be dissolved within a few months. The exclusion of James from the succession to the throne was now proposed; his place was to be taken by the duke of Monmouth, Charles's eldest illegitimate son. A new parliament met in Oct. 1680; the Exclusion bill passed the commons, but was defeated in the lords by the genius of George Savile, marquess of Halifax. The commons refused to consider the alternative plan, which Charles was prepared to accept, of limiting the powers of a Catholic successor. In March 1681 a new parliament met at Oxford, where the London mob could not dominate it, but as the Exclusion bill was introduced immediately, it was dissolved after sitting for one week only. Henceforward Charles governed without parliaments.

It was at this time that the terms Whig and Tory emerged as party names for the supporters and opponents of the Exclusion bill. Charles began to attack the Whigs and had their leader, Shaftesbury, indicted for high treason, but the London grand jury threw out the charge. A writ of *quo warranto* brought against London compelled it to surrender its charter, whereupon a general attack was made on the municipal charters throughout the kingdom. The new charters gave the Tories control over the appointment of municipal officers and the return of the borough members. James returned to England. Some of the defeated Whigs formed the Rye House plot in 1683; its discovery led to the execution of Lord William Russell, earl of Essex, and Algernon Sidney. The Tory reaction had now reached its climax, but Charles was not yet prepared to face another parliament. As a result shortage of income compelled him, in spite of subsidies from Louis XIV, to abandon Tangier (1683) and to allow the navy to decay; meanwhile he could only watch the increase of French power, including the seizure of Strasbourg. He may have been considering a change of policy when he was taken seriously ill on Feb. 2, 1685. He made a profession of the Catholic faith, received the sacrament and died on Feb. 6.

In appearance Charles was tall and dark; besides numerous portraits there is a wax effigy, taken from the corpse, in Westminster abbey. He was active, walked rapidly and was an excellent horseman; he loved all outdoor sports, but was happiest at sea. He was a keen patron of the turf and rode well. He had an excellent constitution, was careful about his diet and rarely drank to excess. His manners were excellent; he was affable and easy, but too good-natured to be able to refuse requests. His wit was more suitable for a private gentleman than for a king, but was free from malice. His fits of anger were rare and brief. His memory was excellent. His gaiety, good nature and freedom from pretense made him generally popular. His notorious lasciviousness contained no "seraphic" element; he accepted the mistresses chosen for him. The sums he spent on them did not seriously embarrass his finances, but made it difficult for him to ask parliament for money for other purposes.

He had no legitimate children; the most important of his many illegitimate children were: by Lucy Walter, James Scott, duke of Monmouth and Buccleuch (1649–1685); by Lady Castlemaine (later duchess of Cleveland), Charles, Henry and George Fitzroy, dukes of Southampton, Grafton and Northumberland; by the duchess of Portsmouth, Charles Lennox, duke of Richmond; by Nell Gwyn, Charles Beauclerk, duke of St. Albans; by Catherine Peg, Charles FitzCharles, earl of Plymouth.

Charles once said that "he was no atheist, but he could not think God would make a man miserable only for taking a little pleasure out of the way." He inclined toward Roman Catholicism, partly on political grounds, but Halifax, perhaps reflecting Charles's own view, thought that creed most compatible with his lax morality. The date of his change of belief is uncertain, but he was not reconciled to Rome until his deathbed, and attended Anglican services regularly during his life. He was a good judge of sermons and did not object to remonstrances so long as he was not expected to reform and they were in good taste. His desire for toleration was based not on principle, but on indifference and good nature and the memory of his promises. Charles was interested in science, had his own laboratory, and gave the Royal society its charter. He encouraged applied science especially when it concerned navigation; his knowledge of naval architecture was praised by Samuel Pepys, but was considered by most contemporaries to be greater than his rank permitted. He patronized the theatre and enjoyed the lighter forms of literature.

The reign was politically sterile because Charles's achievements were undone and his foreign policy reversed by the revolution of 1688; but the transfer of power from the crown to the house of commons went on steadily during the existence of the Long Parliament of the Restoration. It was a time of administrative progress, notably in the navy and in the treasury system, and between 1660 and 1688 the administration of the old colonial empire reached its highest point of efficiency. Charles himself contributed by his interest in naval, commercial and colonial expansion, but sacrificed these objects too easily to his personal and dynastic policy. Attempts to vindicate the latter have not been wholly successful, for much of his conduct admits no justification. He was too lazy and fond of pleasure to apply himself steadily to business, but energetic on occasion and always intelligent. Charles Halifax notes his powers of dissimulation. He was unwilling to face prolonged opposition, being determined "not to go on his travels again." He was selfish and callous but not vindictive. During the reign there was great material and intellectual progress and some improvement in manners.

Writers who denounce the morals of the age rely too much on Pepys and Philibert Gramont. The tendency has been to judge the country at large by Charles's characteristics, and to dwell on his vices without considering his gifts. Closer study modified many of the older verdicts.

CHARLES I AND II, kings of France. By the French, Charles the Great, Roman emperor and king of the Franks, is reckoned the first of the series of French kings named Charles (*see* CHARLES THE GREAT).

Similarly the emperor Charles II the Bald (*q.v.*) is reckoned as Charles II of France. In some enumerations the emperor Charles III the Fat (*q.v.*) is reckoned as Charles II of France, Charlemagne not being included in the list and Charles the Bald being styled Charles I.

CHARLES III, THE SIMPLE (879–929), king of France, was a posthumous son of Louis the Stammerer and of his second wife Adelaide. On the deposition of Charles the Fat in 887 he was excluded from the throne because of his youth; but during the reign of Odo, who had succeeded Charles, he gained the recogni-

tion of a certain number of notables and was crowned at Reims by Archbishop Fulk (*q.v.*) on Jan. 28, 893. He now got some support from the emperor Arnulf; and Odo ceded part of Neustria to him. When Odo died (Jan. 1, 898), he obtained possession of the whole kingdom. His most important act was the treaty of Saint Clair-sur-Epte with the Normans in 911. Some of them were baptized; the kernel of the duchy of Normandy (*q.v.*) was ceded to them; but the story of the marriage of their chief Rollo with the king's sister Gisela, related by the chronicler Dudo of Saint Quentin, is very doubtful. The same year Charles, on the invitation of the barons, took possession of the kingdom of Lotharingia. But the Neustrian barons, jealous of the growth of the royal authority and discontented with the favour shown by the king to his counsellor Hagano, rebelled and in 922 elected Robert, brother of King Odo, in place of Charles. Robert was killed in the battle of Soissons (923), but the victory remained with his party, who elected Rudolph, duke of Burgundy, king. In his extremity Charles trusted himself to Herbert, count of Vermandois, who deceived him and imprisoned him at Château-Thierry and afterward at Péronne, where he died on Oct. 7, 929. In 907 he had married Frederona, sister of Bovo, bishop of Châlons. After her death he married Eadgifu (Odgiva), daughter of Edward the Elder, king of the English, who was the mother of Louis IV.

See A. Eckel, *Charles le Simple* (Paris, 1899).

CHARLES IV (1294–1328), king of France, called THE FAIR, third and youngest son of Philip IV, received La Marche from his father as an appanage in 1311 (it was raised to the rank of *comté-pairie* in 1316). When his brother Philip V died on Jan. 2, 1322, leaving one daughter and a widow with child (another daughter), Charles acted on the precedent established by Philip in 1316 and took the crown without difficulty, leaving to his two nieces only their mother's dowry, the county of Burgundy.

The most important fact of his reign was the renewal of war with England. In 1323 Charles ordered the building of a castle at Saint Sardos, a small village of Agenais, depending on the priory of Sarlat, his direct vassal, with which he had concluded a treaty of *pariage*. The seneschal of Guienne thought this a usurpation of his English master's rights, stormed the town and hanged a number of Charles's officers. Thereupon, on July 1, 1324, Charles pronounced the confiscation of Aquitaine and Ponthieu, alleging also that Edward II had made no homage.

A French army occupied all Aquitaine, except Bordeaux, Bayonne and Saint Sever. In March 1325 Edward sent his wife Isabella (Charles's sister) to Paris to negotiate; and, as Edward did not wish to go to France to do homage, she obtained (Sept. 1325) that Aquitaine and Ponthieu should go to her son Edward, who would make homage. But Charles claimed to keep Agenais and La Réole, and Edward II rejected the arrangement. Aquitaine and Ponthieu were again confiscated, and the overthrow of Edward II prevented any English resistance. On March 31, 1327, Isabella, now regent of England, signed a treaty by which her son recovered his fief, less Agenais and Bazadais.

This renewal of the war made serious financial difficulties for Charles, who had to put civil offices up for auction, to increase duties on trade and to make the salaries of the magistrates dependent on the exaction of heavy fines.

On the pretext of a crusade to free Armenia from the Turks, he obtained from the pope a tithe levied on the clergy, which he kept for his own use. As his predecessors had done, he confiscated the property of the Lombard bankers. He summoned a number of assemblies to obtain support for these measures and to try again to reform the coinage, but they were held only locally, in *bailliages* and *sénéchaussées*. In 1326, he was satisfied with a meeting of prelates and barons in Meaux, which accepted the principle of a subsidy for the war.

Charles died at Vincennes on Feb. 1, 1328. He had been married three times, first to Blanche of Burgundy, who in May 1314 was convicted of adultery, then to Mary of Luxembourg (d. 1324) and thirdly to Joan of Évreux. He left one daughter by Mary; and his widow was with child.

(F. CT.)

CHARLES V (1337–1380), king of France, called THE WISE was born at the château of Vincennes, on Jan. 21, 1337, the son of John II and Bona of Luxembourg. In 1349 he became dauphin of the Viennois by purchase from Humbert II and in 1355 he was created duke of Normandy. After the battle of Poitiers (1356) where his father was taken prisoner by the English, he arranged for the government of Normandy and proceeded to Paris, where he took the title of lieutenant of the kingdom. During the years of John II's imprisonment in England, Charles assumed the government of France. He summoned the states general of northern France (*Langue d'Oïl*) to Paris in Oct. 1356 to obtain men and money to carry on the war. But under the leadership of Étienne Marcel, provost of the Parisian merchants and president of the third estate, and Robert le Coq, bishop of Laon, president of the clergy and a partisan of Charles II of Navarre, the states refused any aid except on conditions which Charles declined to accept. They demanded the dismissal of a number of the royal ministers, the establishment of a commission elected from the three estates to regulate the dauphin's administration and of another board to act as council of war; also the release of Charles of Navarre, who had been imprisoned by King John. The estates of Languedoc summoned to Toulouse, also made protests against misgovernment but they agreed to raise a war levy on terms to which the dauphin acceded. Charles sought the alliance of his uncle, the emperor Charles IV, to whom he did homage at Metz as dauphin of the Viennois, and he was also made imperial vicar of Dauphiné, thus acknowledging the imperial jurisdiction. But he gained small material advantage from these proceedings. The states general were again convoked in Feb. 1357. Their demands were more moderate than in the preceding year, but they nominated members to replace certain obnoxious persons on the royal council and demanded the right to assemble without the royal summons and certain administrative reforms. In return they promised to raise and finance an army of 30,000 men, but the money—a tithe levied on the annual revenues of the clergy and nobility—voted for this object was not to pass through the dauphin's hands. Charles had to yield and issued an ordinance of reform (March 3), but the agreement was annulled by letters from King John, who announced at the same time the conclusion of a two years' truce. Charles had tried to escape from the power of the reformers by leaving Paris, but he returned for a new meeting of the estates in the autumn of 1357.

Meanwhile, Charles of Navarre had been released by his partisans and, allying himself with Étienne Marcel, had become a popular hero in Paris. The dauphin was obliged to receive him and to undergo an apparent reconciliation. In Paris Marcel was supreme. He forced his way into the dauphin's palace (Feb. 22, 1358), and Charles's servants, Jean de Conflans, marshal of Champagne, and Robert de Clermont, marshal of Normandy, were murdered before his eyes. Charles was powerless against Marcel, who compelled him to take the title of regent to prevent the possibility of further intervention from King John. But he fled from Paris on March 28, obtained from the provincial assemblies the money refused him by the states general and blockaded the capital by the seizure of Meaux and Montereau. Charles of Navarre, now in league with the English and master of lower Normandy and of the approaches to Paris, returned to the immediate neighbourhood of the city, and Marcel found himself driven to avowed cooperation with the dauphin's enemies, the English and the Navarrese. In defiance of a recent ordinance prohibiting provincial assemblies, Charles presided over the estates of Picardy and Artois and then over those of Champagne. The states general of 1358 summoned to Compiègne instead of Paris, granted a large aid.

The condition of northern France was rendered more desperate by the outbreak (May–June 1358) of the peasant revolt known as the Jacquerie, which was repressed with a ferocity far exceeding the excesses of the rebels. Within the walls of Paris, Jean Maillart had formed a royalist party; Marcel was assassinated (July 31, 1358), and the dauphin entered Paris two days later. A reaction in Charles's favour had set in, and the estates of 1359

supported him in repudiating the treaty of London (1359), which King John had signed in anxiety for his personal freedom, and voted money unconditionally for the continuation of the war.

From this time the estates were only once convoked by Charles, who thenceforward professed to summon the assembly of notables or provincial bodies. Charles of Navarre was induced to end his war with the regent. But Edward III landed at Calais in October; and a great part of the country was exposed to depredations from the English troops. In the scarcity of money Charles had recourse to the debasement of the coinage, which suffered no less than 22 variations in the two years before the treaty of Brétigny. This disastrous financial expedient was made good later, the coinage being established on a firm basis during the 16 years of Charles's reign in accordance with the principles of Nicolas Oresme. On the conclusion of peace, King John was restored to France, but being unable to raise his ransom, he returned in 1364 to England, where he died in April, leaving the crown to Charles, who was crowned at Reims on May 19.

The new king found an able servant in Bertrand du Guesclin, who won a victory over the Navarrese troops at Cocherel and took prisoner their best general, Jean de Grailly, captal de Buch. The establishment of Charles's brother, Philip the Bold, in the duchy of Burgundy, though it constituted in the event a serious menace to the monarchy, put an end to the king of Navarre's ambitions in that direction. A treaty of peace between the two kings was signed in 1365, by which Charles of Navarre gave up Mantes, Meulan and the county of Longueville in exchange for Montpellier. Negotiations were renewed in 1370, and Charles of Navarre did homage for his French possessions, though he was then considering a new alliance with Edward III. Du Guesclin undertook to free France from the depredations of the "free companies," mercenary soldiers put out of employment by the cessation of the war. An attempt to send them on a crusade against the Turks failed, and Du Guesclin led them to Spain to put Henry of Trastamara on the throne of Castile. By the marriage of Philip the Bold with Margaret of Flanders, Charles detached the Flemings from the English alliance. Then as soon as he had restored something like order in the internal affairs of the kingdom, he provoked a quarrel with the English.

The text of the treaty of Brétigny presented technical difficulties of which Charles availed himself. The English power in Guienne was weakened by the disastrous Spanish expedition of the Black Prince. Edward, prince of Wales, whom Charles summoned before the *parlement* of Paris in Jan. 1369 to answer the charges preferred against him by his subjects, thus expressly repudiating the English sovereignty in Guienne. The Black Prince failed to obey. War was renewed at once on the Gascon frontier. Between 1371 and 1373 Poitou and Saintonge were reconquered by Du Guesclin, and soon the English had to abandon all their territory north of the Garonne. John IV of Brittany (Jean de Montfort) had won his duchy with English help by the defeat of Charles of Blois, the French nominee, at Auray in 1364. His sympathies remained English, and he was obliged to take refuge in England (1373) and later in Flanders, while the English only retained a footing in two or three coast towns. Charles restrained his armies from fighting an uneven pitched battle with the English; they contented themselves with defensive and guerrilla tactics. The towns were defended, and the English left to do as they would in the countryside. There they could not maintain themselves; they gradually retreated until in 1380 only Bayonne, Bordeaux, Brest, Cherbourg and Calais were still in English hands.

Charles alleged in 1378 that he had proof of Charles of Navarre's treasonable designs. He seized the Norman towns held by the Navarrese, while Henry of Trastamara invaded Navarre. The conditions of peace that he imposed rendered his lifelong enemy at last powerless. A premature attempt to annex the duchy of Brittany to the royal domain failed. Charles summoned the duke to Paris in 1378 and on his nonappearance committed one of his rare errors of policy by confiscating his duchy. But the Bretons rose to defend their independence and recalled their duke. The matter was still unsettled when Charles, whose health had always been delicate, died at Vincennes on Sept. 16, 1380. His wife, Joan of Bourbon, had died in 1378, and the succession devolved on their elder son Charles, a boy of 12. Their younger son was Louis, later duke of Orléans.

Personally Charles was no soldier. He owed the signal successes of his reign partly to his skilful choice of advisers and administrators, to his chancellors Jean and Guillaume de Dormans and Pierre d'Orgemont, to Hugues Aubriot, provost of Paris, Bureau de la Rivière and others; partly to a singular coolness and subtlety in the exercise of a not overscrupulous diplomacy, which made him a dangerous enemy. He had learned prudence and self-restraint in the troubled times of the regency, and did not lose his moderation in success. He modelled his private life on that of his predecessor St. Louis, but was no fanatic in religion, for he refused his support to the violent methods of the Inquisition in southern France and allowed the Jews to return to the country, at the same time confirming their privileges. His support of the schismatic pope Clement VII at Avignon although apparently sincere, was a major political blunder.

Charles V was a student of astrology, medicine, law and philosophy and collected a large and valuable library at the Louvre, which became the nucleus of the great Bibliothèque Royale. He gathered round him a group of distinguished writers and thinkers, among whom were Raoul de Presles, Philippe de Mézières, Nicolas Oresme and others. The ideas of these men were applied by him to the practical work of administration, though he confined himself chiefly to the consolidation and improvement of existing institutions. The power of the nobility was lessened by restrictions which, without prohibiting private wars, made them practically impossible. The feudal fortresses were regularly inspected by the central authority, many of them were demolished on the pretext that they might serve as vantage points for the English invaders, and the nobles themselves became in many cases paid officers of the king. The feudal nobility was further weakened by the accession to the *noblesse* of many townsmen. The indirect taxes imposed in 1360 to provide for the ransom of his father and the direct taxes decreed for the war against the companies in 1363 were levied throughout his reign.

The system of royal commissioners for the collection of the revenues took shape, with *élus* in the districts and a board of "general councillors" at the head. Charles's military reforms were intended to restore discipline and to provide for the regular pay of the soldiers and for the levying of archers from among the peasantry. After 1372 he established a strong navy, which under Jean de Vienne threatened the English coast between 1377 and 1380. A special reserve fund was instituted for financing the war, and taxation became heavier, since Charles set no limits to the gratification of his tastes in the collection of jewels, precious objects and books or of his love of building, examples of which are the renovation of the Louvre and the erection of the palace of Saint Paul in Paris. Charles, in spite of his merits, was not popular, and revolts of discontented taxpayers, especially in the south, broke out during the last months of his reign.

CHARLES VI (1368–1422), king of France, son of Charles V and Joan of Bourbon, was born in Paris on Dec. 3, 1368. He received the appanage of Dauphiné at his birth and was thus the first of the princes of France to bear the title of dauphin from infancy. Charles V entrusted his education to Philippe de Mézières and fixed his majority at 14. He succeeded to the throne in 1380 at the age of 12, and the government was divided between his paternal uncles, Louis, duke of Anjou, John, duke of Berry, Philip the Bold, duke of Burgundy, and his mother's brother, Louis II, duke of Bourbon. Considerable discontent existed in the south of France at the time of the death of Charles V, and when the duke

of Anjou reimposed certain taxes which the late king had remitted at the end of his reign there were revolts at Puy and Montpellier. Paris, Rouen, the cities of Flanders, with Amiens, Orléans, Reims and other French towns, also rose (1382) in revolt against taxation. Charles VI marched to the help of the count of Flanders against the insurgents headed by Philip van Artevelde and gained a complete victory at Roosebeke (Nov. 27, 1382). Strengthened by this success the king, on his return to Paris in the following January, exacted vengeance on the citizens by fines, executions and the suppression of the privileges of the city. The help sent by the English to the Flemish cities resulted in a second Flemish campaign. In 1385 Jean de Vienne made an unsuccessful descent on the Scottish coast, and Charles equipped a fleet at Sluys for the invasion of England; but a series of delays ended in the destruction of the ships by the English.

In 1385 Charles married Isabella (*q.v.*; otherwise Elizabeth, or Isabeau), daughter of Stephen II, duke of Bavaria. Three years later, with the help of his brother, Louis, duke of Touraine (later duke of Orléans), he threw off the tutelage of his uncles, whom he replaced by Bureau de la Rivière and others among his father's counsellors, nicknamed by the royal princes the *marmousets* because of their humble origin. Two years later he deprived the duke of Berry of the government of Languedoc. The opening years of Charles VI's effective rule promised well, but excess in gaiety of all kinds undermined his constitution, and in Aug. 1392 he had an attack of madness at Le Mans, when on his way to Brittany to force from John V the surrender of his cousin Pierre de Craon, who had tried to assassinate the constable Olivier de Clisson in the streets of Paris. Other attacks followed, and it became evident that Charles was unable permanently to sustain the royal authority. Clisson, Bureau de la Rivière, Jean Le Mercier and the other *marmousets* were driven from office, and the royal dukes regained their power. The rivalries between the most powerful of these (the duke of Burgundy, who during the king's attacks of madness practically ruled the country, and the duke of Orléans) were a constant menace to order.

In 1396 peace with England seemed assured by the marriage of Richard II with Charles's daughter Isabella, but the Lancastrian revolution of 1399 destroyed the diplomatic advantages gained by this union. In France the country was disturbed by the papal schism. At an assembly of the clergy held in Paris in 1398 it was resolved to refuse to recognize the authority of Benedict XIII, who succeeded Clement VII as schismatic pope at Avignon. The question became a party one; Benedict was supported by Louis of Orléans, while Philip the Bold and Paris university opposed him. Obedience to Benedict's authority was resumed in 1403, only to be withdrawn again in 1408, when the king declared himself the guardian and protector of the French church, which was indeed for a time self-governing. Edicts further extending the royal power in ecclesiastical affairs were even issued in 1418, after the schism was at an end.

The king's intelligence became yearly feebler, and in 1404 on the death of Philip the Bold the influence of the duke of Orléans increased. Queen Isabella, who had generally supported the Burgundian party, was now practically separated from her husband and was replaced by a young Burgundian lady, Odette de Champdivers. Isabella was freely accused of intrigue with the duke of Orléans. The relations between John the Fearless of Burgundy and the duke of Orléans became more embittered, and on Nov. 23, 1407, Orléans was murdered in the streets of Paris at the instigation of his rival. In vain did the king, in his rare moments of sanity, try to reconcile the factions by the peace of Chartres in 1409. The young duke Charles of Orléans formed alliances with the dukes of Berry, Bourbon and Brittany and others constituting the party known as the Armagnacs (*see* ARMAGNAC) against the Burgundians, who had gained the upper hand in the royal council. In 1411 John the Fearless contracted an alliance with Henry IV of England, and civil war began in the autumn, but in 1412 the Armagnacs in their turn sought English aid and, by promising the sovereignty of Aquitaine to the English king, gave John the opportunity of posing as defender of France. In Paris the Burgundians were hand in hand with the corporation of the butchers, who were the leaders of the Parisian populace. The malcontents, who took their name from one of their number, Simon Caboche, penetrated into the palace of the dauphin Louis and demanded the surrender of the unpopular members of his household. A royal ordinance, promising reforms in administration, was promulgated on May 27, 1413, and some of the royal advisers were executed. The king and the dauphin, powerless in the hands of Duke John and the Parisians, appealed secretly to the Armagnac princes, who entered Paris in September. As a result the ordinance extracted by the Cabochiens was rescinded, and many of the insurgents were banished from the city.

In the next year Henry V of England, after concluding an alliance with Burgundy, resumed the pretensions of Edward III to the crown of France, and in 1415 followed the disastrous battle of Agincourt. The two elder sons of Charles VI, the dauphin Louis duke of Guienne, and John, duke of Touraine, died in 1415 and 1417, and Charles, count of Ponthieu, became heir apparent. Paris was governed by Bernard of Armagnac, constable of France, who expelled all suspected of Burgundian sympathies and treated Paris like a conquered city. Queen Isabella was imprisoned at Tours, but escaped to Burgundy. The capture of Paris by the Burgundians on May 29, 1418, was followed by a series of horrible massacres of the Armagnacs; and in July, Duke John and Isabella, who assumed the title of regent, entered Paris. Meanwhile Henry V had completed the conquest of Normandy. The murder of John the Fearless in 1419 under the eyes of the dauphin Charles threw the Burgundians definitely into the arms of the English, and his successor Philip the Good, in concert with Queen Isabella, concluded (1420) the treaty of Troyes with Henry V, who became regent of France. Charles VI had long been of no account in the government, and the state of neglect in which he existed at Senlis induced Henry V to undertake the reorganization of his household. He went to Paris in Sept. 1422 and died on Oct. 21.

BIBLIOGRAPHY.—The chief authorities for the reign of Charles VI are: *Chronica Caroli VI*, written by a monk of Saint Denis, commissioned officially to write the history of his time, ed. by L. F. Bellaguet with a French trans. 6 vol. (1839–52); Jean Juvénal des Ursins, *Chronique de Charles VI*, printed by D. Godefroy in *Histoire de Charles VI* (Paris, 1653), chiefly an abridgment of the monk of St. Denis's narrative; a fragment of the *Grandes Chroniques de Saint Denis* covering the years 1381–83 ed. J. Pichon (1864); correspondence printed by J. J. Champollion-Figeac in *Lettres de rois*, vol. ii (Paris, 1839); Société de l'Histoire de France, *Choix de pièces inédites rel. au règne de Charles VI*, 2 vol. ed. by L. Douët d'Arcq (Paris, 1863–64); J. Froissart, *Chroniques;* Enguerrand de Monstrelet, *Chroniques*, covering the first half of the 15th century, Eng. trans., 4 vol. (1809); *Chronique des quatre premiers Valois*, by an unknown author, ed. S. Luce (Paris, 1862). *See* also A. Coville, in E. Lavisse, *Histoire de France*, iv. 267 ff. (Paris, 1902); E. CHARLES VII (1403–1461), king of France, fifth son of Charles VI and Isabella of Bavaria, was born in Paris on Feb. 22, 1403. The count of Ponthieu, as he was called in his boyhood, was betrothed in 1413 to Mary of Anjou, daughter of Louis II, duke of Anjou and king of Sicily, and spent the next two years at the Angevin court. He received the duchy of Touraine in 1416 and became dauphin (on his brother John's death) and lieutenant-general of the kingdom in 1417 and regent in Dec. 1418; but his authority in northern France was paralyzed in 1419 by the murder of John the Fearless, duke of Burgundy, in his presence at Montereau. Although the deed was apparently not premeditated, as the English and Burgundians declared, it ruined Charles's cause for the time. He was disinherited by the treaty of Troyes in 1420 and at the time of his father's death in 1422 had retired to Méhun-sur-Yèvre, near Bourges, which had been the nominal seat of government since 1418. He was recognized as king in Touraine, Berry and Poitou, in Languedoc and other provinces of southern France; but the English power in the north was presently increased by the provinces of Champagne and Maine, as the result of the victories of Cravant (1423) and Verneuil (1424). The Armagnac administrators who had been driven out of Paris by the duke of Bedford gathered round the young king, nicknamed the "king of Bourges"; but he was weak

in body and mind and was under the domination of Jean Louvet and Tanguy du Chastel, the instigators of the murder of John the Fearless, and other discredited partisans. The power of these favourites was shaken by the influence of the queen's mother, Yolande of Aragon, duchess of Anjou. She sought the alliance of John V, duke of Brittany, who, however, vacillated throughout his life between the English and French alliance, concerned chiefly to maintain the independence of his duchy. His brother, Arthur of Brittany, earl of Richmond (comte de Richemont), was reconciled with the king and became constable in 1425, with the avowed intention of making peace between Charles and the duke of Burgundy. Richemont caused the assassination of Charles's favourites Pierre de Giac and Le Camus de Beaulieu and imposed one of his own choosing, Georges de la Trémoïlle, an adventurer who rapidly usurped the constable's power. For five years (1427–32) a private war between these two exhausted the Armagnac forces, and central France returned to anarchy.

Meanwhile Bedford had established settled government throughout the north of France, and in 1428 he advanced to the siege of Orléans. For the movement which was to lead to the deliverance of France from the English invaders, *see* JOAN OF ARC. The siege of Orléans was raised by her efforts on May 8, 1429, and two months later Charles VII was crowned at Reims. But the court put every difficulty in the way of her military career, and received the news of her capture before Compiègne (1430) with indifference. No measures were taken for her deliverance or her ransom, and Normandy and the Ile de France remained in English hands. Fifteen years of anarchy and civil war intervened before peace was restored. The duke of Bedford died in 1435, and in the same year Philip the Good of Burgundy concluded a treaty with Charles at Arras, after fruitless negotiations for an English treaty. From this time Charles's policy was strengthened. La Trémoïlle had been assassinated in 1433 by the constable's orders, with the connivance of Yolande of Aragon. For his former favourites were substituted energetic advisers, his brother-in-law Charles of Anjou, Dunois (the famous bastard of Orléans), Pierre de Brézé, Richemont and others. Richemont entered Paris on April 13, 1436, and in the next five years the finance of the country was restored. Charles himself commanded the troops who captured Pontoise in 1441 and made a successful expedition in the south in 1442. Meanwhile the *Ecorcheurs* plundered the kingdom; the princes of the blood and the great nobles made a formidable league against the crown in 1440 which included Charles I, duke of Bourbon John II, duke of Alençon, John IV of Armagnac, and the dauphin, afterward Louis XI. The revolt broke out in Poitou in 1440 and was known as the Praguerie. Charles repressed the rising and finally brought over the rebel nobles individually by considerable concessions. In 1444 a truce was concluded with England at Tours, and Charles proceeded to organize a regular army, consisting of cavalry from the nobility (grouped in companies and paid by the king) and of plebeian infantry (the *francs archers*). The central authority was gradually made effective.

Charles collected the *taille* and the *aides* without summoning the estates; and he weakened the *parlement* of Paris and extended the scope of the royal justice by creating *parlements* at Toulouse and at Bordeaux and by maintaining the Normandy exchequer in office. The bailiffs were inspected by commissaries. Insurrections in Normandy and domestic troubles weakened the English in France. The conquest of Normandy was completed by the battle of Formigny (April 15, 1450). Guienne was conquered in 1451 by Dunois, but not subdued, and another expedition was necessary in 1453, when Talbot was defeated and slain at Castillon. Meanwhile in 1450 Charles had resolved on the rehabilitation of Joan of Arc. This was granted in 1456 by the Holy See. The only foothold retained by the English on French ground was Calais. The change which made Charles take an active part in public affairs is said to have been largely due to the influence of Agnes Sorel, who became his mistress in 1444 and died in 1450. Pierre de Brézé, who had had a large share in the repression of the Praguerie, obtained through her a dominating influence over the king. Charles and René of Anjou retired from court, and the greater part of the members of the king's council were drawn from the bourgeois classes, for example Jacques Coeur (*q.v.*). These men revived economic life; ruined peasants were given tax relief, corporations reorganized, the Lyons fairs reestablished, and the coinage restored. It was by the zeal of these councillors that Charles obtained the surname of "The Well-Served."

Charles continued his father's general policy in church matters. He desired to preserve as far as possible the liberties of the Gallican church. With the council of Constance (1414–18) the Great Schism was practically healed. Charles, while careful to protest against its renewal, supported the anti-papal contentions of the French members of the council of Basel (1431–49), and in 1438 he promulgated the Pragmatic Sanction at Bourges, by which the patronage of ecclesiastical benefices was removed from the Holy See, while certain interventions of the royal power were admitted. Bishops and abbots were to be elected, in accordance with ancient custom, by their clergy. After the English had evacuated French territory Charles still had to cope with feudal revolt and with the hostility of the dauphin, who was in open revolt in 1446 and for the next ten years ruled like an independent sovereign in Dauphiné. He took refuge in 1457 with Charles's most formidable enemy, Philip of Burgundy. Charles VII nevertheless found means to prevent Philip from attaining his ambitions in Lorraine and in Germany. But the dauphin succeeded in embarrassing his father's policy at home and abroad, and had his own party in the court.

Charles VII died at Mehun-sur-Yèvre on July 22, 1461. He believed that he was poisoned by his son, who cannot, however, be accused of anything more than an eager expectation of his death.

Samaran, 2 vol. (Paris, 1933–45).

CHARLES VIII (1470–1498), king of France, was the only son of Louis XI. On the death of Louis in 1483 Charles, a lad of 13, was incapable of governing. Until 1492 he abandoned the government to his sister Anne of Beaujeu, who defended the royal authority against the claims of the states general (1484) and against the blundering agitation known as "la guerre folle." Anne negotiated Charles's marriage with Anne of Brittany in 1491 and thus connected the dukedom with the French crown. Charles, however, dreamed of glory.

Urged by his favourite, Étienne de Vesc, he threw off the yoke of the Beaujeus and their policy. He proposed at first to claim the rights of the house of Anjou, to which Louis XI had succeeded, on the kingdom of Naples and to use this as a steppingstone to Constantinople and to his own coronation as emperor of the east. He sacrificed everything to this policy, signed disastrous treaties with England and Aragon to keep his hands free, and set out in 1494. On May 12, 1495, he entered Naples in great pomp, clothed in the imperial insignia. A general coalition, the League of Venice, was formed against him, however, and he was forced to return to France. He was preparing a fresh expedition when he died as the result of an accident at Amboise on April 8, 1498.

See J. S. C. Bridge, *A History of France from the Death of Louis XI* 2 vol. (Oxford, 1921–24); H. F. Delaborde, *Expédition de Charles VIII en Italie* (Paris, 1888).

CHARLES IX (1550–1574), king of France, was born at Saint Germain-en-Laye, on June 27, 1550, the second son of Henry II and of Catherine de Medici. He became king, under his mother's regency, in 1560, on the death of his brother Francis II. Charles seems to have had some promising qualities as a young man, but his health was poor. Stricken with tuberculosis (as were other members of his family) and subject to hallucinations, with a tendency to mental derangement from his childhood, he finally ruined his constitution by strenuous exercise and undue indulgence in hunting. Proclaimed of age on Aug. 17, 1563, he submitted

docilely to his mother's continued authority. To strengthen the prestige of the crown, she took him on a two years' tour of his kingdom; but he really cared little for the business of government, in which he intervened only spasmodically. In 1570 he was married to Elizabeth of Austria, daughter of the Holy Roman emperor Maximilian II. Meanwhile, however, his brother the duke of Anjou (later Henry III of France) had won victories over the Huguenots at Jarnac and at Moncontour, which aroused Charles's jealousy. When Gaspard de Coligny (*q.v.*) came to court, Charles at first received him warmly and seemed to favour his plan for intervention against the Spaniards in the Low Countries. Then Catherine, anxious to avert the dangers of so rash an undertaking, prevailed on him to abandon Coligny: the massacre of St. Bartholomew's day (1572) was the result. This led to a renewal of civil war, during which there could be no question of enterprises in the Low Countries, whatever Charles's ambitions. Moreover, as his health grew worse, his character changed, to become melancholy and morose. He died on May 30, 1574, leaving a bastard son, Charles, count of Auvergne and later duke of Angoulême, by his mistress Marie Touchet. A pupil of the great Jacques Amyot, the king had had a sincere love of literature, writing poems and a work on hunting, *Traité de la chasse royale* (published 1625; new ed. 1858), as well as making himself the patron of the Pléïade and of Jean Antoine de Baïf's academy.

CHARLES X (1757–1836), king of France from 1824 to 1830, was the fourth child of the dauphin Louis, son of Louis XV and of Marie Josephe of Saxony. He was known before his accession as Charles Philippe, count of Artois. At the age of 16 he married Marie Thérèse of Savoy, sister-in-law of his brother, the count of Provence (Louis XVIII). His youth was passed in scandalous dissipation, which drew upon himself and his coterie the detestation of the people of Paris.

Although lacking military tastes, he joined the French army at the siege of Gibraltar in 1772, merely for distraction. In a few years he had incurred a debt of 56,000,000 fr., a burden assumed by the impoverished state. Prior to the Revolution he took only a minor part in politics, but when it broke out he soon became, with the queen, the chief of the reactionary party at court.

In July 1789 he left France, became leader of the *émigrés* and visited several courts of Europe in the royalist interest.

After the execution of Louis XVI, he received from his brother, the count of Provence, the title of lieutenant general of the realm and, on the death of Louis XVII, that of monsieur.

In 1795 he attempted to aid the royalist rising of La Vendée, landing at the island of Yeu. But he refused to advance farther and to put himself resolutely at the head of his party, although warmly acclaimed by it. Courage failing him, he returned to England, settling first in London, then in Holyrood palace at Edinburgh and afterward at Hartwell. He remained at Hartwell until 1813, returning to France in Feb. 1814 and entering Paris in April, in the track of the Allies. During the reign of his brother, Louis XVIII, he was the leader of the Ultraroyalists, the party of extreme reaction. On succeeding to the throne in Sept. 1824 he won a passing popularity. But his coronation at Reims, with all the gorgeous ceremonial of the old regime, proclaimed his intention of ruling as the most Christian king, by divine right.

It was soon apparent that the weight of the crown would be consistently thrown into the scale of the reactionary forces. The *émigrés* were awarded a milliard as compensation for their confiscated lands; and Gallicans and Liberals alike were offended by measures which threw increased power into the hands of the Jesuits and Ultramontanes. In a few months there were disquieting signs of the growing unpopularity of the king. The royal princesses were insulted in the streets; and on April 29, 1825, Charles, when reviewing the national guard, was met with cries from the ranks of "Down with the ministers!" His reply was, next day, a decree disbanding the citizen army. In 1829 Charles consented unwillingly to try a policy of compromise. Villèle's successor was the vicomte de Martignac, who took Decazes for his model; and in the speech from the throne Charles declared that the happiness of France depended on "the sincere union of the royal authority with the liberties consecrated by the charter."

But Charles had none of the patience and common sense which had enabled Louis XVIII to play with decency the part of a constitutional king. "I would rather hew wood," he exclaimed, "than be a king under the conditions of the king of England"; and when the Liberal opposition obstructed all the measures proposed by a ministry not selected from the parliamentary majority, he lost patience. "I told you," he said, "that there was no coming to terms with these men." Martignac was dismissed; and Prince Jules de Polignac, the very incarnation of clericalism and reaction, was called to the helm of state.

A formidable agitation sprang up, which only served to make the king more obstinate. In opening the session of 1830 he declared that he would "find the power" to overcome the obstacles placed in his path by "culpable manoeuvres." The reply of the chambers was a protest against "the unjust distrust of the sentiment and reason of France"; whereupon they were first prorogued, and on May 16 dissolved. The result of the new elections was a large increase in the opposition; and Charles, on the advice of his ministers, determined on a virtual suspension of the constitution. On July 26 were issued the famous "four ordinances" which were the immediate cause of the revolution.

With singular fatuity Charles had taken no precautions in view of a violent outbreak. Marshal Marmont, who commanded the scattered troops in Paris, had received no orders, beyond a jesting command from the duke of Angoulême to place them under arms "as some windows might be broken." At the beginning of the revolution Charles was at St. Cloud, whence on the news of the fighting he withdrew first to Versailles and then to Rambouillet.

So little did he understand the seriousness of the situation that, when the laconic message "All is over!" was brought to him, he believed that the insurrection had been suppressed.

On realizing that the revolutionaries had been successful he abdicated in favour of his grandson, the duke of Bordeaux (comte de Chambord), and appointed Louis Philippe, duke of Orléans, lieutenant general of the kingdom (July 30). But, on the news of Louis Philippe's acceptance of the crown, he gave up and began a dignified retreat to the sea coast, followed by his suite and surrounded by the infantry, cavalry and artillery of the guard. Beyond sending a corps of observation to follow his movements, the new government did nothing to arrest his escape.

At Maintenon Charles took leave of the bulk of his troops and, proceeding with an escort of about 1,200 men to Cherbourg, took ship there for England on Aug. 16.

For a time he returned to Holyrood palace at Edinburgh, which was again placed at his disposal. He died at Göritz, where he had gone for his health, on Nov. 6, 1836. The best that can be said of Charles X is that, if he did not know how to rule, he knew how to cease to rule. The dignity of his exit was more worthy of the ancient splendour of the royal house of France than the theatrical humility of Louis Philippe's entrance.

Charles, however, was an impossible monarch for the 19th century or perhaps for any other century. He was, it has been said, a typical Bourbon, unable either to learn or to forget, and the closing years of his life he spent in religious austerities, intended to expiate not his failure to grasp a great opportunity but the comparatively venial excesses of his youth. This, at any rate, represents the general verdict of history. It is interesting, however, to note that the liberal-minded and shrewd critic of men, King Leopold I of the Belgians, formed a different estimate.

In a letter of Nov. 18, 1836, addressed to Princess (afterward Queen) Victoria, Leopold wrote: "History will state that Louis XVIII was a most liberal monarch, reigning with great mildness and justice to his end, but that his brother, from his despotic and harsh disposition, upset all the other had done, and lost the throne. Louis XVIII was a clever, hard-hearted man, shackled by no principle, very proud and false. Charles X an honest man, a

kind friend, an honourable master, sincere in his opinions, and inclined to do everything that is right. That teaches us what we ought to believe in history as it is compiled according to ostensible events and results known to the generality of people."

CHARLES I. (1288–1342), king of Hungary, the son of Charles Martell of Naples, and Clemencia, daughter of the emperor Rudolph, was known as Charles Robert before his enthronement as king of Hungary in 1309. He claimed the Hungarian Crown, as the grandson of Stephen V., under the banner of the pope, and was crowned at Esztergom after the death of the last Arpad, Andrew III. (1301), but was forced the same year to surrender the Crown to Wenceslaus II. of Bohemia (1289–1306), who in 1305 transferred his rights to Duke Otto of Bavaria. Duke Otto was taken prisoner by the Hungarians and Charles was enthroned at Budapest on June 15, 1309, though his installation was not regarded as valid till he was crowned with the sacred crown (which was recovered from the robber barons) at Székesfehérvár on Aug. 27, 1310. After three years of warfare Charles at length put down all the elements of rapine and disorder at Rozgony (June 15, 1312). His foreign policy aimed at the aggrandizement of his family, but Hungary also benefited greatly from it. His most successful achievement was the union with Poland for mutual defence against the Habsburgs and the Czechs, which was accomplished by the Convention of Trencsén (1335), confirmed the same year at the brilliant Congress of Visegrád, where all the princes of Central Europe met to compose their differences. The result of the congress was a combined attack by the Magyars and the Poles upon the emperor Louis and his ally Albert of Austria, which was decided in Charles's favour in 1337. Charles wished to unite the kingdoms of Hungary and Naples under his eldest son Louis, but was frustrated by Venice and the pope, who feared that Hungary might become the dominant Adriatic Power. He was, however, compensated for this disappointment by his compact (1339) with his ally and brother-in-law, Casimir of Poland, whereby it was agreed that Louis should succeed to the throne of Poland on the death of the childless Casimir. Charles was a statesman of the first rank, who not only raised Hungary once more to the rank of a great Power, but enriched and civilized her. In character he was pious, courtly and valiant, popular alike with the nobility and the middle classes, whose increasing welfare he did so much to promote, and much beloved by the clergy. His court was famous throughout Europe as a school of chivalry.

Three sons, Louis, Andrew and Stephen survived him. He died on July 16, 1342, and was laid beside the high altar at Székesfehérvár, the ancient burial place of the Arpads.

See Béla Kerékgyartó, *The Hungarian Royal Court under the House of Anjou* (Hung.) (Budapest, 1881); *Rationes Collectorum Pontif. in Hungaria* (Budapest, 1887); *Diplomas of the Angevin Period,* edit. Imre Nagy (Hung. and Lat.) vols. i.–iii. (Budapest, 1878, etc.).

CHARLES I. (1226–1285), king of Naples and Sicily and count of Anjou, was the seventh child of Louis VIII. of France and Blanche of Castile. Louis died a few months after Charles's birth and was succeeded by his son Louis IX. (St. Louis), and on the death in 1232 of the third son, John, count of Anjou and Maine, those fiefs were conferred on Charles. In 1246 he married Beatrice, daughter and heiress of Raymond Bérenger V., the last count of Provence, and after defeating James I. of Aragon and other rivals with the help of his brother, the French king, he took possession of his new county. In 1248 he accompanied Louis in the crusade to Egypt, but on the defeat of the Crusaders he was taken prisoner with his brother. Shortly afterwards he was ransomed, and returned to Provence in 1250. Charles's ambition aimed at wider fields, and he extended his influence by the subjugation of Marseille in 1257, and two years later several communes of Piedmont recognized his suzerainty. In 1262 Pope Urban IV. determined to destroy the power of the Hohenstaufen in Italy, and offered the kingdoms of Naples and Sicily, in consideration of a yearly tribute, to Charles of Anjou. After long negotiations he accepted the Sicilian and Neapolitan crowns, and in 1264 he sent a first expedition of Provençals to Italy; he also collected a large army and navy in Provence and France with the help of King Louis, and by an alliance with the cities of Lombardy was able to send part of his force overland. Pope Clement IV. confirmed the Sicilian agreement on conditions even more favourable to Charles, who sailed in 1265, and conferred on the expedition all the privileges of a crusade. After narrowly escaping capture by Manfred's fleet he reached Rome safely, where he was crowned king of the Two Sicilies. The land army arrived soon afterwards, and on Feb. 26, 1266, Charles encountered his rival Manfred the bastard of the emperor Frederick II., at Benevento (*q.v.*), where after a hard-fought battle Manfred was defeated and killed, and the whole kingdom was soon in Charles's possession. Then Conradin, Frederick's grandson and last legitimate descendant of the Hohenstaufen, came into Italy, where he found many partisans among the Ghibellines of Lombardy and Tuscany, and among Manfred's former adherents in the south. He was totally defeated by Charles at Tagliacozzo (Aug. 23, 1268); taken prisoner, he was tried as a rebel and executed at Naples.

Charles was now one of the most powerful sovereigns of Europe, for besides ruling over Provence and Anjou and the kingdom of the Two Sicilies, he was imperial vicar of Tuscany, lord of many cities of Lombardy and Piedmont, and as the pope's favourite practically arbiter of the papal states, especially during the interregnum between the death of Clement IV. (1268) and the election of Gregory X. (1272). In 1272 he took part with Louis IX. in a crusade to north Africa. The election of Rudolph of Habsburg as German king, and that of Nicholas III. to the Holy See (1277), diminished Charles's power, for the new pope set himself to compose the difference between Guelphs and Ghibellines in the Italian cities, but at his death Charles secured the election of his henchman Martin IV. (1281), who recommenced persecuting the Ghibellines. But the cruelty of the French rulers of Sicily provoked in 1282 the rebellion known as the Sicilian Vespers (*see* VESPERS, SICILIAN). Charles determined to subjugate the island and sailed with his fleet for Messina. The city held out until Peter III. of Aragon arrived in Sicily, and a Sicilian-Catalan fleet under the Calabrese admiral, Roger de Lauria, completely destroyed that of Charles. In May 1284 Roger de Lauria appeared before Naples and destroyed another Angevin fleet commanded by Charles's son, who was taken prisoner. Charles came to Naples with a new fleet from Provence, and was preparing to invade Sicily again, when he died at Foggia on Jan. 7, 1285. An extremely able soldier and a skilful statesman, his inordinate ambition and his cruelty created enemies on all sides, and led to the collapse of the edifice of dominion which he had raised.

CHARLES II. (1250–1309), king of Naples and Sicily, son of Charles I., had been captured by Ruggiero di Lauria in the naval battle at Naples in 1284, and when his father died he was still a prisoner in the hands of Peter of Aragon. In 1288 Charles was liberated on the understanding that he was to retain Naples alone, Sicily being left to the Aragonese, and to induce his cousin Charles of Valois to renounce the kingdom of Aragon given to him by Pope Martin IV. He went to Rieti, where the new pope Nicholas IV. immediately absolved him from all the conditions he had sworn to observe, crowned him king of the Two Sicilies (1289), and excommunicated Alphonso, while Charles of Valois, in alliance with Castile, prepared to take possession of Aragon. Alphonso III., the Aragonese king, being hard pressed, had to promise to withdraw the troops he had sent to help his brother James in Sicily, to renounce all rights over the island, and pay a tribute to the Holy See. But Alphonso died childless in 1291 before the treaty could be carried out, and James took possession of Aragon, leaving the government of Sicily to the third brother Frederick. The new pope Boniface VIII., elected in 1294 at Naples under the auspices of King Charles, mediated between the latter

and James, and a most dishonourable treaty was signed. An attempt was made to bribe Frederick into consenting to the arrangement, but being backed up by his people he refused, and was afterward crowned king of Sicily. The ensuing war was fought with great fury and peace was not made until 1302 at Caltabellotta, Charles II giving up all rights to Sicily and agreeing to the marriage of his daughter Leonora to King Frederick; the treaty was ratified by the pope in 1303. Charles died in Aug. 1309, and was succeeded by his son Robert.

(Brussels, 1838), gives a good general sketch; R. Sternfeld, *Karl von Anjou als Graf von Provence* (1888); Charles's connection with north Italy is dealt with in Merkel's *La Dominazione di Carlo d'Angiò in Piemonte e in Lombardia* (Turin, 1891), while the R. Deputazione di Storia Patria Toscana has recently published a *Codice diplomatico delle relazioni di Carlo d'Angiò con la Toscana;* Durrieu, *Archives angevines de Naples* (Toulouse, 1866–1867). M. Amari's *La Guerra del Vespro Siciliano*, 8th ed. (Florence, 1876) is a valuable history, but is prejudiced and should be compared with L. Cadier, *Essai sur l'administration du royaume de Sicile sous Charles I et Charles II d'Anjou* (1891, *Bibl. des écoles françaises d'Athènes et de Rome*, fasc. 59), which contains many documents.

CHARLES II (1332–1387), called THE BAD, king of Navarre and count of Évreux, was a son of Joan of France, queen of Navarre, by her marriage with Philip, count of Évreux. He succeeded his mother in 1349 and married Joan, daughter of John II of France, in 1352. Trouble soon arose between John II and his son-in-law. The promised dowry had not been paid, and the county of Angoulême, formerly belonging to Joan of France was then in the possession of John's favourite, the constable Charles of La Cerda. In Jan. 1354 the constable was assassinated, and John was forced to make a treaty at Mantes and to compensate Charles for the loss of Angoulême by a large grant of lands, chiefly in Normandy. In Normandy, Charles was partly responsible for some unrest and was seized by the French king at Rouen in April 1356, remaining in captivity until Nov. 1357, after John became a prisoner in England. Charles was then considered by Étienne Marcel and his party as a suitable rival to the dauphin (afterward King Charles V). Peace was made, but the dauphin's failure to restore to Charles his confiscated estates led again to war, quickly followed by a new treaty, after which Charles took part in suppressing the peasant rising known as the *Jacquerie*.

However, in June 1358, he returned to Paris and became captain-general of the city, which was soon besieged by the dauphin. Charles left Paris just before the murder of Marcel in July and continued his alternate policy of war and peace, until the conclusion of the treaty of Brétigny in May 1360 deprived him of the alliance of the English and compelled him to make peace with King John. When the duchy of Burgundy became vacant in Nov. 1361, Charles made an unsuccessful claim for it.

In July 1362, he invaded Aragon in alliance with Peter the Cruel, king of Castile, but he soon deserted his new ally for Peter IV, king of Aragon. In turn he made treaties of alliance with the kings of Castile and Aragon and with Edward of England. Then in 1371 he returned to the allegiance of Charles V of France. He was accused in 1378 of attempting to poison the king of France and other prominent persons and of other crimes; his French estates were seized (except Cherbourg which he sold to the English). After the death of Charles V, in 1380, the king of Navarre did not interfere in the internal affairs of France. His lands in France were handed over to his eldest son Charles, who governed them with the consent of the new king, Charles VI. Charles died on Jan. 1, 1387, and was succeeded by his son Charles; one of his daughters, Joan, dowager duchess of Brittany, became the wife of Henry IV of England.

CHARLES III (1361–1425), called THE NOBLE, king of Navarre and count of Évreux, was the eldest son of Charles II the Bad (*q.v.*) and was married in 1375 to Eleanor, daughter of Henry II, king of Castile. Charles became king of Navarre in 1387, and in contrast to his father's reign his was a period of peace and order. He regained Cherbourg (which had been handed over by Charles II to Richard II of England) in 1393 and exchanged it for certain other lands in France in 1403. He was created duke of Nemours and made a peer of France.

Charles died at Olite on Sept. 8, 1425. After the death of his two sons in 1402 the king secured his kingdom for his daughter Blanche (d. 1441), who took for her second husband John (afterward John II, king of Aragon); and the cortes of Navarre swore to recognize Charles (*q.v.*), prince of Viana, her son by this marriage, as king after his mother's death.

CHARLES I (KARL EITEL; in Rum. CAROL; 1839–1914), first king of Rumania, was born on April 20, 1839, the second son of Prince Charles Antony of Hohenzollern-Sigmaringen, head of the South German and Catholic branch of the Hohenzollerns, who had acted as minister-president of Prussia immediately before Bismarck. His mother was the daughter of the grand duke Charles of Baden and of Stéphanie de Beauharnais. Educated at Dresden and at Bonn, he became an officer in the Prussian army and served against Denmark in 1864. The leaders of the newly united principalities of Moldavia and Walachia, balked of their original desire for a foreign prince, looked abroad again after the overthrow of Alexander John Cuza and, failing Philip of Flanders, offered the throne to Charles, with the tacit approval of Napoleon III. By a plebiscite held in Rumania on April 20, 1866, Charles was almost unanimously elected prince; he had to be smuggled into the country because of the hostility of Russia, Austria and Turkey, but rapidly gained general recognition. Given wide powers under the constitution of July 11, 1866, he showed great tact in dealing with the struggles between the Liberal and Conservative parties, and his administrative, economic and military reforms earned him deep respect at home and abroad.

In 1869 he married Elizabeth (*q.v.*), daughter of Prince Hermann of Wied and a Lutheran; he had already undertaken to educate his children in the Orthodox faith, despite papal disapproval. The sympathy of Rumanians with France in the Franco-German War led to a wave of hostility against the German prince, which, coinciding with a railway scandal, led him to offer abdication. With difficulty persuaded to remain, Charles was later to win great popularity when he led a Rumanian and Russian contingent to victory at Plevna in the Russo-Turkish War of 1877–78. As a consequence of his vigorous action, Rumania secured recognition from the powers of its complete independence of Turkey in 1878 and was proclaimed a kingdom on March 26, 1881, Charles and his consort being crowned on May 22. As king, Charles proved most successful in home policy, greatly improving the financial and military position of his country. He and the queen, who became known as a poetess under the name of Carmen Sylva, gave special encouragement to the fine arts. In foreign policy Charles remained true to Germany, signing a secret treaty with the Central Powers in 1883; the failure of Rumania, still Francophile, to implement that treaty in Aug. 1914 broke him down. On Oct. 10, 1914, he died in his palace at Sinaia. As the only child of Charles's marriage, a daughter, had died in 1874, the succession was settled on his brother's son, who became Ferdinand I of Rumania.

CHARLES II (1661–1700), king of Spain, the son of Philip IV by his second marriage with Maria, daughter of the emperor Ferdinand III, was born on Nov. 11, 1661. Weak, indolent and almost imbecile from his birth, Charles was brought up under the tutelage of his Austrian mother, who was later exiled from court by the younger Don John of Austria, a natural son of Philip IV. In 1679, Charles married Maria Louisa of Orleans, thereby satisfying French interests, which were still more advanced by his acceptance of the treaty of Ratisbon, June 1684. On the death of the French princess in the stifling atmosphere of the Spanish court, Charles married Maria Ana of Neuberg in

1689, and Austrian interests were again promoted. Always decrepit in mind and body, the king, driven wild by the conflict between his wish to transmit his inheritance to "the illustrious house of Austria," his own kin, and the belief instilled into him by the partisans of the French claimant that only the power of Louis XIV. could avert the dismemberment of the empire, was at last reduced to an abject condition. Under pressure from the cardinal archbishop of Toledo, Portocarrero, he finally made a will in favour of Philip, duke of Anjou, grandson of Louis XIV., thereby ending the inglorious line of the Spanish Habsburgs. He died on Nov. 1, 1700.

See M. de Villars, *Lettres* (1868); P. de Villars, *Mémoires de la Cour d'Espagne* (1893); G. Maura Gamaza, *Carlos II. y su Corte*, 2 vols. (1915). (For a genealogical table of the Spanish Habsburgs, *see* HABSBURG.)

CHARLES III. (1716–1788), king of Spain, born on Jan. 20, 1716, was the first son of the second marriage of Philip V. with Elizabeth Farnese of Parma. In 1732 he was sent to rule as duke of Parma by right of his mother, and two years later, 1734, made himself master of Naples and Sicily and began there the work of internal reform which he afterwards continued in Spain. On the death of his half-brother Ferdinand VI. he became king of Spain and resigned the Two Sicilies to his third son, Ferdinand.

As king of Spain his foreign policy was disastrous. His strong family feeling and his detestation of England, which was unchecked after the death of his wife, Maria Amelia, daughter of Frederick Augustus II. of Saxony, in 1760, led him into the Family Compact with France. Spain was entangled in the close of the Seven Years' War, to her great loss. In 1779 he was, somewhat reluctantly, led to join France and the American insurgents against England. His internal government was on the whole beneficial to the country. He improved sanitation, suppressed lawlessness, encouraged trade and industry, and constructed roads and canals. Although a sincere Roman Catholic, he consented to the expulsion of the Jesuits from Spain, reduced the number of idle clergy, and rendered the Inquisition ineffectual. When he died on Dec. 14, 1788, Charles, the greatest of the Spanish Bourbons, left the reputation of an enlightened monarch.

CHARLES IV. (1748–1819), king of Spain, second son of Charles III. and his wife Maria Amelia of Saxony, was born on Nov. 11, 1748. The elder brother was set aside as imbecile and epileptic. Charles married Maria Luisa of Parma, his first cousin, who, on his succession to the throne in 1788, directed affairs with the assistance of her lover Godoy (*q.v.*). The king was too slothful to have more than a passive part in the direction of his own Government. If he ever understood that his kingdom was treated as a mere dependence by France, he consoled himself with a belief in his divine right and the sanctity of his person. When he was told that his son Ferdinand was appealing to Napoleon against Godoy, he took the side of the favourite, and when the populace rose at Aranjuez in 1808 he abdicated to save the minister. He took refuge in France, and being imprisoned with his son he was with difficulty restrained from assaulting him. Finally he abdicated in favour of Napoleon and died at Rome on Jan. 20, 1819.

See General Gomez de Arteche (*Historia del Reinado de Carlos IV.*) in the *Historia General de España de la Real Academia de la Historia* (1892, etc.); A. Savine, *L'Abdication de Bayonne.* (1908).

CHARLES IX. (1550–1611), king of Sweden, the youngest son of Gustavus Vasa and Margareto Lejonhufrud, was born on Oct. 4, 1550. By his father's will he received the duchy of Södermanland (Sudermania) in 1560. In 1568 he and his brother John led the rebellion against Eric XIV., but when John became king, as John III., the relations between the two brothers were strained. Duke Charles was the centre of the opposition to John's attempts to romanize Sweden on the one hand, and he resisted all the king's efforts to restrict his authority as duke of Södermanland on the other, though in 1587 he was obliged to resign his claim to autonomy within his own duchy. The religious question came to a crisis on the death of John III. in 1592, when his eldest son, Sigismund, a devoted Catholic who was already king of Poland, succeeded to the throne of Sweden. Duke Charles came forward as the champion of the Protestant majority, who were alarmed lest Sigismund should attempt to re-catholicize Sweden; it was with his assent that they held the famous Synod or "Uppsala-möte" Feb. 1593, which proclaimed Sweden's adherence to the Augsburg Confession; and when Sigismund arrived in Sweden Charles, who had governed jointly with the Estates during his absence, backed by an army, compelled him, before he could be crowned, to guarantee to maintain the Uppsala convention, thereby recognizing that Sweden was essentially a Protestant state. In Aug. 1594 when Sigismund left for Poland, Charles was left in control of affairs, and in 1595 he was elected regent by the *Riksdag* of Söderköping. He ruled firmly, almost despotically. Roman Catholicism was suppressed. In May 1595 the peace of Teusin was concluded with Russia, who recognized Sweden's title to Narva and Estonia. By 1597 however, the country was in a state of civil war. Charles had quarrelled with the council over their refusal to make war on Finland, whose ruler, Klas Fleming, refused to recognize Charles's authority as opposed to that of Sigismund. Sigismund forbade the summoning of the *Riksdag* which supported Charles, and authorized the council to govern alone, but Charles summoned the *Riksdag* when the council was not sitting, and persuaded it to give him all the powers of government. He then sailed to Finland and captured Abo. Sigismund landed at Kalmar in Sweden with an army, in July 1598, but though large numbers of the nobles flocked to his standards he was regarded as a heretic by the majority of the Swedish nation. Charles defeated him at Stängebro on Sept. 25, 1598, after which he fled for aid to Poland, though he had promised to disband his forces and to abide by the decision of the Estates. He was formally deposed by the *Riksdag* in 1599, and on Feb. 24, 1600, the diet of Linköping declared that he and his posterity had forfeited the Swedish throne, and passing over duke John, the second son of John III., a youth of ten, recognized Duke Charles as king under the title of Charles IX.

Charles proceeded to conquer Finland, and to take cruel vengeance on the nobles who had opposed him. He did not, however, style himself king until March 6, 1604, after Duke John had formally renounced his claim, and was not crowned until March 15, 1607. His short reign was a period of uninterrupted warfare. In the long war with Poland (1600–60), begun in his reign, he was on the whole unsuccessful, his severest defeat being at Kirkholm (Sept. 1605) (*see* CHODKIEWICZ, JAN KAROL). Sweden and Poland also supported rival claimants to the tsardom in Russia. In 1610 Charles, who had concluded an alliance with the tsar Basil against Sigismund in 1609 and who aimed at obtaining the county of Keksholm for Sweden, sent an army under Jakob de la Gardie (*q.v.*) to Moscow. After his defeat by the Polish general, Zolkievski, at Klutsjino (June, 1610) and the collapse of Basil, de la Gardie seized Keksholm and Novgorod in 1611. In the same year Christian IV. (*q.v.*) of Denmark declared war on Sweden, partly as a result of Charles's pretensions to Lapland, and his veto on trade with Riga and Kurland and his foundation of the city of Göteborg (Gothenburg), partly from an ambition to conquer Sweden. Christian besieged Kalmar (whence the name "Kalmar War," given to this war). In July, 1611, Charles IX. fought an indecisive battle near that city, and on the 28th the castle of Kalmar was surrendered treacherously. Old and worn out, Charles died on Oct. 30, leaving his son, Gustavus Adolphus, to carry on war with Denmark and Russia. As a ruler Charles IX. is the link between his great father Gustavus Vasa and his still greater son. He consolidated the work of Gustavus Vasa, the creation of a great Protestant state: he prepared the way for the erection of the Protestant empire of Gustavus Adolphus. By his first wife Marie, daughter of the elector palatine Louis VI., he had six children, of whom only one daughter, Catherine, survived; by his second wife, Christina, daughter of Adolphus, duke of Holstein-Gottorp, he had five children, including Gustavus Adolphus and Charles Philip, duke of Finland.

CHARLES X. (CHARLES GUSTAVUS) (1622–1660), king of Sweden, son of John Casimir, count palatine of Zweibrücken, and Catherine, sister of Gustavus Adolphus, was born at Nyköping Castle on Nov. 8, 1622. He learnt the art of war under the great Lennart Torstensson, being present at the second battle of Breitenfeld and at Jankowitz. From 1646 to 1648 he frequented the Swedish court. It was supposed that he would marry the queen regnant, Christina, and to compensate her cousin for a broken half-promise she declared him (1649) her successor, despite the opposition of the senate headed by Axel Oxenstjerna. In 1648 he was appointed generalissimo of the Swedish forces in Germany, and acted as Swedish plenipotentiary at the executive congress of Nuremberg, assembled (1650) to execute the details of the peace of Westphalia. As the recognized heir to the throne, his position on his return to Sweden was a difficult one, in view of the unpopularity of the queen. Charles, therefore, wisely withdrew to the isle of Öland till the abdication of Christina (June 5, 1654) called him to the throne.

The beginning of his reign was devoted to the healing of domestic discords and in preparation for a new policy of conquest. He contracted a political marriage (Oct. 24, 1654) with Hedwig Leonora, the daughter of Frederick III., duke of Holstein-Gottorp, by way of securing a future ally against Denmark. The two great pressing national questions, war and the restitution of the alienated crown lands, were considered at the *Riksdag* which assembled at Stockholm in March 1655. The war question was decided in three days by a secret committee presided over by the king, who easily persuaded the delegates that a war with Poland was necessary and might prove very advantageous; but the consideration of the question of the subsidies due to the crown for military purposes was postponed to the following *Riksdag* (*see* SWEDEN: *History*). On July 15 Charles quitted Sweden to engage in his Polish adventure. By the time war was declared he had at his disposal 50,000 men and 50 warships. Hostilities had already begun with the occupation of Dünaburg (Dvinsk) in Polish Livonia by the Swedes (July 1, 1655), and the Polish army encamped among the marshes of the Netze concluded a convention (July 25) whereby the palatinates of Posen and Kalisz placed themselves under the protection of the Swedish king. The Swedes then entered Warsaw without opposition and occupied the whole of Great Poland. The Polish king, John Casimir, fled to Silesia. Meanwhile Charles pressed on towards Cracow, which was captured after a two months' siege. The fall of Cracow extinguished the last hope of the boldest Pole; but before the end of the year an extraordinary reaction began in Poland itself. On Oct. 18 the Swedes invested the fortress-monastery of Czestochowa, but the place was heroically defended; and after a seventy days' siege the besiegers were compelled to retire with great loss.

This astounding success elicited an outburst of popular enthusiasm which gave the war a national and religious character. The tactlessness of Charles, the rapacity of his generals, the barbarity of his mercenaries, his refusal to legalize his position by summoning the Polish diet, his negotiations for the partition of the very state he affected to befriend, awoke the long slumbering public spirit of the country. In the beginning of 1656 John Casimir returned from exile and the Polish army was reorganized and increased. By this time Charles had discovered that it was easier to defeat the Poles than to conquer Poland. His chief object, the conquest of Prussia, was still unaccomplished, and a new foe arose in the elector of Brandenburg, alarmed by the ambition of the Swedish king. Charles forced the elector, indeed, at the point of the sword to become his ally and vassal (treaty of Königsberg, Jan. 17, 1656); but the Polish national rising now imperatively demanded his presence in the south. For weeks he scoured the interminable snow-covered plains of Poland in pursuit of the Polish guerillas, penetrating as far south as Jaroslav in Galicia, by which time he had lost two-thirds of his 15,000 men with no apparent result. His retreat from Jaroslav to Warsaw, with the fragments of his host, amidst three converging armies, in a marshy forest region, intersected in every direction by well-guarded rivers, was one of his most brilliant achievements. But his necessities were overwhelming. On June 21 Warsaw was retaken by the Poles, and four days later Charles was obliged to purchase the assistance of Frederick William by the treaty of Marienburg. On July 18–20 the combined Swedes and Brandenburgers, 18,000 strong, after a three days' battle, defeated John Casimir's army of 50,000 at Warsaw and reoccupied the Polish capital; but this brilliant feat of arms was altogether useless, and when the suspicious attitude of Frederick William compelled the Swedish king at last to open negotiations with the Poles, they refused the terms offered, the war was resumed, and Charles concluded an offensive and defensive alliance with the elector of Brandenburg (treaty of Labiau, Nov. 20) whereby it was agreed that Frederick William and his heirs should henceforth possess the full sovereignty of East Prussia. In the meantime the hostile Dutch dominated Danzig, and the tsar started a campaign against the Swedish Baltic provinces.

The alliance of the elector had now become indispensable on almost any terms. So serious, indeed, were the difficulties of Charles X. in Poland, in spite of the assistance of the elector and of George Rákóczy II., prince of Transylvania, that it was with extreme satisfaction that he received the tidings of the Danish declaration of war (June 1, 1657) which enabled him honourably to emerge from the inglorious Polish imbroglio. He had learnt from Torstensson that Denmark was most vulnerable if attacked from the south, and, imitating the strategy of his master, he fell upon her with a velocity which paralyzed resistance. At the end of June 1657, at the head of 6,000 seasoned veterans, he executed a rapid march from the interior of Poland to Stettin, and reached the borders of Holstein on July 18. The Danish army at once dispersed and the duchy of Bremen was recovered by the Swedes, who in the early autumn swarmed over Jutland and firmly established themselves in the duchies. But the fortress of Fredriksodde (Fredericia) on the Little Belt held Charles's little army at bay from mid-August to mid-October, while the fleet of Denmark, after a stubborn two days' battle, compelled the Swedish fleet to abandon its projected attack on the Danish islands. In July an offensive and defensive alliance was concluded between Denmark and Poland. The elector of Brandenburg joined the league against Sweden, and compelled Charles to accept the proffered mediation of Cromwell and Mazarin. The negotiations foundered, however, upon the refusal of Sweden to refer the points in dispute to a general peace-congress, and Charles was still further encouraged by the capture of Fredriksodde (Oct. 23–24). In the middle of December 1657 began the great frost which was to be so fatal to Denmark. On Jan. 28, 1658, Charles X. arrived at Hadersley (Hadersleben) in South Jutland, when it was estimated that in a couple of days the ice of the Little Belt would be firm enough to bear even the passage of a mail-clad host to the island of Fünen. Early in the morning of Jan. 30 the Swedish king gave the order to start, the horsemen dismounting where the ice was weakest, and cautiously leading their horses as far apart as possible, when they swung into their saddles again, closed their ranks and made a dash for the shore. The whole of Fünen was won with the loss of only two companies of cavalry, which disappeared under the ice while fighting with the Danish left wing. Charles, with his eyes fixed steadily on Copenhagen, resolved to cross the frozen Great Belt also. After some hesitation, he accepted the advice of his chief engineer officer Erik Dahlberg, who acted as pioneer throughout, and chose the more circuitous route from Svendborg, by the islands of Langeland, Laaland and Falster, in preference to the direct route from Nyborg to Korsør, which would have been across a broad, almost uninterrupted expanse of ice. On the night of Feb. 5 the transit began, the cavalry leading the way through the snow-covered ice, which quickly thawed beneath the horses' hoofs so that the infantry which followed after had to wade through half an ell of sludge, fearing every moment lest the rotting ice should break beneath their feet. At three o'clock in the afternoon, Dahlberg leading the way, the army reached Grimsted in Laaland without losing a man. On Feb. 8 Charles reached Falster. On the 11th he stood safely on the soil of Sjaelland (Zealand). The medal struck to commemorate "the glorious transit of the Baltic Sea" bore the haughty inscription: *Natus hoc debuit uni.*

The crushing effect of this unheard-of achievement on the Danish Government found expression in the treaties of Taastrup (Feb. 18) and Roskilde (Feb. 26, 1658), whereby Denmark sacrificed nearly half her territory to save the rest (*see* DENMARK: *History*). But even this was not enough for the conqueror. Military ambition and greed of conquest moved Charles X. to what, divested of all its pomp and circumstance, was an outrageous act of political brigandage. At a council held at Gottorp (July 7), Charles X. resolved, without any warning, in defiance of all international equity, to let loose his veterans upon Denmark a second time. For the details of this second struggle, with the concomitant diplomatic intervention of the western powers, who were determined to prevent the closing of the Sound, *see* FREDERICK III., king of Denmark, and DENMARK: *History*. Only after great hesitation would Charles X. consent to reopen negotiations with Denmark direct, at the same time proposing to exercise pressure upon the enemy by a simultaneous winter campaign in Norway. Such an enterprise necessitated fresh subsidies from his already impoverished people, and obliged him in December 1659 to cross over to Sweden to meet the estates, whom he had summoned to Gothenburg. The lower estates murmured at the imposition of fresh burdens; and Charles had need of all his adroitness to persuade them that his demands were reasonable and necessary. At the very beginning of the *Riksdag*, in January 1660, it was noticed that the king was ill; but he spared himself as little in the council-chamber as in the battle-field, till death suddenly overtook him on the night of Feb. 12–13, 1660, in his thirty-eighth year.

CHARLES XI. (1655–1697), king of Sweden, the only son of Charles X. and Hedwig Leonora of Holstein-Gottorp, was born in the palace at Stockholm on Nov. 24, 1655. His father, who died when the child was in his fourth year, appointed a regency of five great ministers of state with the queen as president. For the history of the regency, of the settlement of the Danish and Russian loans, and the later humiliating dependence on France (*see* SWEDEN: *History*). The young king's education was neglected. When he attained his majority, he was ignorant of the very rudiments of state-craft and almost illiterate. It was the disaster of the Scanian war which first called forth his sterling qualities and hardened him into a premature manhood.

In 1675 the Brandenburgers, Pomeranians and Danes had overrun Pomerania and Bremen, and the Danes were preparing to invade Sweden itself. Amidst universal anarchy, the young king, barely twenty years of age, inexperienced, ill-served, snatching at every expedient, worked day and night in his newly-formed camp in Scania (Skåne) to arm the nation for its mortal struggle. The Danes launched invasion from three directions in 1676. The victory of Fyllebro (Aug. 17, 1676), when Charles and his commander-in-chief S. G. Hjelmfeld routed a Danish division, was the first Swedish success, and on Dec. 4, on the tableland of Helgonabäck, near Lund, the young Swedish monarch defeated Christian V. of Denmark, who also commanded his army in person. After a ferocious contest, the Danes were practically annihilated. The battle of Lund was, relatively to the number engaged, one of the bloodiest engagements of modern times. More than half the combatants (8,357, of whom 3,000 were Swedes) actually perished on the battle-field. All the Swedish commanders, notably John Gyllenstierna, showed remarkable ability, but the chief glory of the day indisputably belongs to Charles XI. This great victory restored to the Swedes their self-confidence and prestige. In the following year, Charles with 9,000 men routed 12,000 Danes near Landskrona (July 15, 1678). This proved to be the last pitched battle of the war, the Danes never again venturing to attack their once more invincible enemy in the open field. In Germany, the Swedes, faced by the Great Elector, lost ground. In 1679 Louis XIV. dictated the terms of a general pacification, and Charles XI., who bitterly resented "the insufferable tutelage" of the French king, acquiesced in a peace which at least left his empire practically intact. Both Christian V. of Denmark and Frederick William, the Great Elector, were forced to restore their conquests (*see* SWEDEN: *History*). Good understanding between Denmark and Sweden followed the peace of Lund, and there relations were cemented by the marriage of Charles with Ulrica Leonora, sister of Christian V. Charles devoted the rest of his life to the gigantic task of rehabilitating Sweden by means of a *reduktion*, or recovery of alienated crown lands, a process which involved the examination of every title deed in the kingdom, and resulted in the complete readjustment of the finances. But vast as it was, the *reduktion* represents only a tithe of Charles XI.'s immense activity. Finance, commerce, the national armaments by sea and land, judicial procedure, church government, education, even art and science—everything, in short—emerged recast from his shaping hand. For the strengthening in his reign of the power of the crown, which left Sweden practically an absolute monarchy (*see* SWEDEN: *History*). Charles XI. died on April 5, 1697, in his forty-first year. He had seven children, of whom only three survived him, a son Charles, and two daughters, Hedwig Sophia, duchess of Holstein, and Ulrica Leonora, who ultimately succeeded her brother on the Swedish throne.

After Gustavus Vasa and Gustavus Adolphus, Charles XI. was, perhaps, the greatest of all the kings of Sweden. His modest, homespun figure has indeed been unduly eclipsed by the brilliant and colossal shapes of his heroic father and his meteoric son; yet in reality Charles XI. is far worthier of admiration than either Charles X. or Charles XII. He was in an eminent degree a great master-builder. He found Sweden in ruins, and devoted his whole life to laying the solid foundations of a new order of things which, in its essential features, has endured to the present day.

See Martin Veibull, *Sveriges Storhedstid* (Stockholm, 1881); Frederick Ferdinand Carlson, *Sveriges Historia under Konungarne af Pfalziska Huset* (Stockholm, 1883–1885); Robert Nisbet Bain, *Scandinavia* (Cambridge, 1905); O. Sjögren, *Karl den Elfte ock Svenska Folket* (Stockholm, 1897); S. Jacobsen, *Den nordiske Kriegs Krönicke, 1675–1679* (Copenhagen, 1897); J. A. de Mesmes d'Avaux, *Négociations du comte d'Avaux*, 1693, 1697, 1698 (Utrecht, 1882, etc.).

CHARLES XII. (1682–1718), king of Sweden, the only surviving son of Charles XI. and Ulrica Leonora, daughter of Frederick III. of Denmark, was born on June 17, 1682. He was carefully educated by excellent tutors under the watchful eyes of his parents. Charles XI. personally supervised his son's physical training. He was taught to ride before he was four and at eight he was quite at home in his saddle.

As he grew older his father took him on all his rounds, reviewing troops, inspecting studs, foundries, dockyards and granaries. Thus the lad was gradually initiated into all the *minutiae* of administration. The influence of Charles XI. over his son was, indeed, far greater than is commonly supposed, and it accounts for much in Charles XII.'s character which is otherwise inexplicable, for instance his precocious reserve and taciturnity, his dislike of everything French, and his inordinate contempt for purely diplomatic methods. On the whole, his early training was admirable; but the young prince was not allowed the opportunity of gradually gaining experience under his guardians. At the *Riksdag* assembled at Stockholm in 1697, the estates, jealous of the influence of the regents, offered full sovereignty to the young monarch, the senate acquiesced, and, after some hesitation, Charles at last declared that he could not resist the urgent appeal of his subjects and would take over the government of the realm "in God's name." The subsequent coronation was marked by portentous novelties, the most significant of which was the king's omission to take the usual coronation oath, which omission was interpreted to mean that he considered himself under no obligation to his subjects. The general opinion of the young king was, however, still favourable. His conduct was evidently regulated by strict principle and not by mere caprice. His intense application to affairs is noted by the English minister, John Robinson (1650–1723).

The coalition formed against Sweden by Johann Reinhold

Patkul, which resulted in the outbreak of the Great Northern War (1699), abruptly put an end to Charles XII.'s political apprenticeship, and forced the sword into his hand. The young king resolved to attack Denmark the nearest of his three enemies—Denmark, Poland and Russia—first. The timidity of the Danish admiral Ulrik C Gyldenlöve, and the daring of Charles, who forced his nervous and protesting admiral to attempt the passage of the eastern channel of the Sound, the dangerous *flinterend*, hitherto reputed to be unnavigable, enabled the Swedish king to effect a landing at Humleback in Sjaelland (Zealand), a few miles north of Copenhagen (Aug. 4, 1700). He now hoped to accomplish what his grandfather, fifty years before, had vainly attempted —the destruction of the Danish-Norwegian monarchy by capturing its capital. But for once prudential considerations prevailed, and the short and bloodless war was terminated by the peace of Traventhal (Aug. 18), whereby Frederick IV. conceded full sovereignty to Charles's ally and kinsman the duke of Gottorp, besides paying him an indemnity of 200,000 rix-dollars and solemnly engaging to commit no hostilities against Sweden in future. From Sjaelland Charles now hastened to Livonia with 8,000 men. On Oct. 6 he had reached Pernau, with the intention of first relieving Riga, but, hearing that Narva was in great straits, he decided to turn northwards against the tsar. He set out for Narva on Nov. 13 against the advice of all his generals, who feared the effect on untried troops of a week's march through a wasted land, along boggy roads guarded by no fewer than three formidable passes which a little engineering skill could easily have made impregnable. Fortunately, the first two passes were unoccupied; and the third, Pyhäjoggi, was captured by Charles, who with 400 horsemen put 6,000 Russian cavalry to flight. On Nov. 19 the little army reached Lagena, a village about 9m. from Narva, whence it signalled its approach to the beleaguered fortress, and early on the following morning it advanced in battle array. The attack on the Russian fortified camp began at two o'clock in the afternoon, in the midst of a violent snowstorm; and by nightfall the whole position was in the hands of the Swedes: the Russian army was annihilated. The triumph was as cheap as it was crushing; it cost Charles less than 2,000 men.

After Narva, Charles XII. stood at the parting of ways. His best advisers urged him to turn all his forces against the panic-stricken Muscovites; to go into winter quarters amongst them and live at their expense; to fan into a flame the smouldering discontent caused by the reforms of Peter the Great; and so disable Russia for some time to come. But Charles was determined to punish the treachery of Augustus of Poland (*see* POLAND: *History*). It is easy from the vantage-point of two centuries to criticize Charles XII. for neglecting the Russians to pursue the Saxons; but at the beginning of the 18th century his decision was natural enough. The real question was, which of the two foes was the more dangerous, and Charles had many reasons to think the civilized and martial Saxons far more formidable than the imbecile Muscovites. Charles also rightly felt that he could never trust the treacherous Augustus to remain quiet, even if he made peace with him. To leave such a foe in his rear, while he plunged into the heart of Russia would have been hazardous indeed. From this point of view Charles's whole Polish policy, which has been blamed so long and so loudly—the policy of placing a nominee of his own on the Polish throne—takes quite another complexion: it was a policy not of overvaulting ambition, but of prudential self-defence.

First, however, Charles cleared Livonia of the invader (July 1701), subsequently occupying the duchy of Courland and converting it into a Swedish governor-generalship. In Jan. 1702 Charles established himself at Bielowice in Lithuania, and, after issuing a proclamation declaring that "the elector of Saxony" had forfeited the Polish crown, set out for Warsaw, which he reached on May 14. The cardinal-primate was then sent for and commanded to summon a diet, for the purpose of deposing Augustus. A fortnight later Charles quitted Warsaw, to seek the elector; on July 2 routed the combined Poles and Saxons at Klissow; and three weeks later, captured the fortress of Cracow by an act of almost fabulous audacity. Thus, within four months of the opening of the campaign, the Polish capital and the coronation city were both in the possession of the Swedes. After Klissow, Augustus made every effort to put an end to the war, but Charles would not even consider his offers. By this time, too, he had conceived a passion for the perils and adventures of warfare. His character was hardening, and he deliberately adopted the most barbarous expedients for converting the Augustan Poles to his views.

The campaign of 1703 was remarkable for Charles's victory at Pultusk (April 21) and the long siege of Thorn, which occupied him eight months but cost him only 50 men. On July 2, 1704, with the assistance of a bribing fund, Charles's ambassador at Warsaw, Count Arvid Bernhard Horn, succeeded in forcing through the election of Charles's candidate to the Polish throne, Stanislaus Leszczynski, who could not be crowned however till Sept. 24, 1705, by which time the Saxons had again been defeated at Punitz. From the autumn of 1705 to the spring of 1706, Charles was occupied in pursuing the Russian auxiliary army under Ogilvie through the forests of Lithuania. On Aug. 5, he recrossed the Vistula and established himself in Saxony, where his presence in the heart of Europe at the very crisis of the war of the Spanish Succession, fluttered all the western diplomats. The allies, in particular, at once suspected that Louis XIV. had bought the Swedes. Marlborough was forthwith sent from the Hague to the castle of Altranstädt near Leipzig, where Charles had fixed his headquarters, "to endeavour to penetrate the designs" of the king of Sweden. He soon convinced himself that western Europe had nothing to fear from Charles, and that no bribes were necessary to turn the Swedish arms from Germany to Russia. Five months later (Sept. 1707) Augustus was forced to sign the peace of Altranstädt, whereby he resigned the Polish throne and renounced every anti-Swedish alliance. Charles's departure from Saxony was delayed for twelve months by a quarrel with the emperor. The court of Vienna had treated the Silesian Protestants with tyrannical severity, in direct contravention of the treaty of Osnabrück, of which Sweden was one of the guarantors; and Charles demanded summary and complete restitution so dictatorially that the emperor prepared for war. But the allies interfered in Charles's favour, lest he might be tempted to aid France, and induced the emperor to satisfy all the Swedish king's demands, the maritime Powers at the same time agreeing to guarantee the provisions of the peace of Altranstädt.

Nothing now prevented Charles from turning his victorious arms against the tsar; and on Aug. 13, 1707, he evacuated Saxony at the head of the largest host he ever commanded, consisting of 24,000 horse and 20,000 foot. Delayed during the autumn months in Poland by the tardy arrival of reinforcements from Pomerania, it was not till Nov. 1707 that Charles was able to take the field. On New Year's Day 1708 he crossed the Vistula, though the ice was in a dangerous condition. On July 4, 1708 he cut in two the line of the Russian army, 6m. long, which barred his progress on the Wabis, near Holowczyn, and compelled it to retreat. The victory of Holowczyn, memorable besides as the last pitched battle won by Charles XII., opened up the way to the Dnieper. The Swedish army now began to suffer severely, bread and fodder running short. The Russians slowly retired before the invader, burning and destroying everything in his path. On Dec. 20 it was plain to Charles himself that Moscow was inaccessible. But the idea of a retreat was intolerable to him, so he determined to march southwards instead of northwards as suggested by his generals, and join his forces with those of the hetman of the Dnieperian Cossacks, Ivan Mazepa, who had 100,000 horsemen and a fresh and fruitful land at his disposal. Short of falling back upon Livonia, it was the best plan adoptable in the circumstances, but it was rendered abortive by Peter's destruction of Mazepa's capital Baturin, so that when Mazepa joined Charles at Horki, on Nov. 8, 1708, it was as a ruined man with little more than 1,300 personal attendants (*see* MAZEPA-KOLEDINSKY, IVAN STEPANOVICH). More serious was the destruction of the relief army which Levenhaupt was bringing to Charles from Livonia, and which, hampered by hundreds of loaded wagons, was overtaken and almost destroyed at Lyesna after a two days'

battle against fourfold odds (October). The very elements now began to fight against the perishing but still unconquered host. The winter of 1708 was the severest that Europe had known for a century. By Nov. 1 firewood would not ignite in the open air, and the soldiers warmed themselves over big bonfires of straw. By the time the army reached the little Ukranian fortress of Hadjacz in January 1709, wine and spirits froze into solid masses of ice; birds on the wing fell dead.

Never had Charles XII. seemed so superhuman as during these awful days. It is not too much to say that his imperturbable equanimity, his serene *bonhomie* kept the host together. The frost broke at the end of Feb. 1709, and then the spring floods put an end to all active operations till May, when Charles began the siege of the fortress of Poltava, which he wished to make a base for subsequent operations while awaiting reinforcements from Sweden and Poland. On June 7 a bullet wound put Charles *hors de combat*, whereupon Peter threw the greater part of his forces over the river Vorskla, which separated the two armies (June 19–25). On June 26 Charles held a council of war, at which it was resolved to attack the Russians in their entrenchments on the following day. The Swedes joyfully accepted the chances of battle and, advancing with irresistible *élan*, were, at first, successful on both wings. Then one or two tactical blunders were committed; and the tsar, taking courage, enveloped the little band in a vast semicircle bristling with the most modern guns, which fired five times to the Swedes' once, and swept away the guards before they could draw their swords. The Swedish infantry was well nigh annihilated, while the 14,000 cavalry, exhausted and demoralized, surrendered two days later at Perevolochna on Dnieper. Charles himself with 1,500 horsemen took refuge in Turkish territory.

For the first time in his life Charles was now obliged to have recourse to diplomacy; and his pen proved almost as formidable as his sword. He procured the dismissal of four Russophil grand-viziers in succession, and between 1710 and 1712 induced the Porte to declare war against the tsar three times. But after Nov. 1712 the Porte had no more money to spare; and, the tsar making a show of submission, the sultan began to regard Charles as a troublesome guest. On Feb. 1, 1713 he was attacked by the Turks in his camp at Bender, and made prisoner. Charles lingered on in Turkey 15 months longer, in the hope of obtaining a cavalry escort sufficiently strong to enable him to restore his credit in Poland. Disappointed of this last hope, and moved by the despairing appeals of his sister Ulrica and the senate to return to Sweden while there was still a Sweden to return to, he quitted Demotika on Sept. 20, 1714, and attended by a single squire arrived unexpectedly at midnight, on Nov. 11, at Stralsund.

For the historical events of the following years *see* SWEDEN: *History*. Here it need only be said that Sweden, during the course of the Great Northern War, had innumerable opportunities of obtaining an honourable and even advantageous peace, but they all foundered on the dogged refusal of Charles to consent to the smallest concession to his despoilers. Even now he would listen to no offers of compromise, and after defending Stralsund with desperate courage till it was a mere rubbish heap, returned to Sweden after an absence of 14 years. Here he collected another army of 20,000 men, with which he so strongly entrenched himself on the Scanian coast in 1716 that his combined enemies shrank from attacking him, whereupon he assumed the offensive by attacking Norway in 1717, and again in 1718, in order to conquer sufficient territory to enable him to extort better terms from his enemies. It was during this second adventure that he met his death. On Dec. 11, when the Swedish approaches had come within 280 paces of the fortress of Fredriksten, which the Swedes were closely besieging, Charles looked over the parapet of the foremost trench, and was shot through the head.

CHARLES XIII. (1748–1818), king of Sweden and Norway, the second son of Adolphus Frederick, king of Sweden, and Louisa Ulrica, sister of Frederick the Great, was born at Stockholm on Oct. 7, 1748. In 1772 he co-operated in the revolutionary plans of his brother Gustavus III. (*q.v.*). During the Russo-Swedish War of 1788 he served as admiral of the fleet at the battles of Hogland (June 17, 1788) and Öland (July 26, 1789). On the death of Gustavus III., Charles, now duke of Sudermania, acted as regent of Sweden till 1796; but the real ruler of the country was Gustaf Adolf Reuterholm (*q.v.*). These four years may be briefly described as alternations of fantastic Jacobinism and ruthless despotism. On the accession of Gustavus IV. (Nov. 1796), the duke became a mere cipher in politics till March 13, 1809, when those who had dethroned Gustavus IV. appointed him regent, and finally elected him king. But by this time he was prematurely decrepit, and Bernadotte (*see* CHARLES XIV JOHN) took over the government as soon as he landed in Sweden (1810). By the union of 1814 Charles became the first king of Sweden and Norway. He married his cousin Hedwig Elizabeth Charlotte of Holstein-Gottorp (1759–1818), but their only child died in infancy (1798). Charles XIII., who for eight years had been king only in title, died on Feb. 5, 1818.

CHARLES XIV JOHN (CARL JOHAN; BERNADOTTE) (1763–1844), king of Sweden and Norway, born at Pau in the French province of Béarn, Jan. 26, 1763, was the son of Henri Bernadotte (1711–1780), an *avocat*, and Jeanne St. Jean (1725–1809). Several of the ancestors on each side had been weavers. The family name of Deu Pouey had been changed to Bernadotte in the early 17th century (after the name of a house taken over from the distaff side). He was baptized Jean, known as Jean Baptiste, and later added the name Jules; his regular signature was merely "J. Bernadotte." Of his childhood and youth it is known only that he was repeatedly ill, and that he probably attended a Benedictine school in Pau for at least a short period.

In 1780, five months after his father's death, Bernadotte enlisted in the army of Louis XVI, in the Royal-la-Marine regiment. In varied service he became successively grenadier, corporal, sergeant, quartermaster, sergeant major, and early in 1790 adjutant, the highest rank among noncommissioned officers. The Revolution created difficulties within the army and between army and citizenry, but Bernadotte stood staunchly for maintenance of authority and judicial processes—once leading a group of under-officers in defense of their colonel in a disagreement with revolutionary civil authorities. Soon legislation opened the way for non-nobles to become officers, and early in 1792 Bernadotte was elected a lieutenant (the commission was dated as of Nov. 6, 1791). He was attached to the 36th regiment and went into action along the Rhine with Adam Custine. In the defeat of May 17, 1793, a panic was begun when a group of volunteers fired on their own cavalry; Bernadotte sprang into the midst of the chaos, and with a fiery speech restored order and reorganized the battalion for the fight. Here he was at his best, in one of those fine gestures of self-forgetfulness to be repeated again and again in the crises of campaigns to come. He went through all the ranks, becoming captain in 1793, and in 1794 passing from lieutenant colonel to colonel, on to brigadier general and general of division (Oct. 22). He served in the army of the Sambre and Meuse with General Jean Baptiste Kléber (1794–95), and distinguished himself for his ability to inspire troops in desperate situations. In 1796 he campaigned in north Germany. Here, as in the Low Countries, he was marked as one of the disciplinarians of the

army, trying to save the population from plundering by soldiery and winning an unusual degree of respect from the inhabitants.

In 1797 came the first meeting between Bernadotte and Napoleon, when the general from the army of the Rhine led 20,000 troops to reinforce General Bonaparte in Italy. Both were proud and ambitious, but the Corsican was cool, unscrupulous, eager only for power; Bernadotte showed the characteristics of his Gascon forebears—vain, emotional, loyal, eager chiefly for glory. The two spectacular leaders seemed to sense rivalry and cross-purposes from the first, and the soldiers in their armies were none too friendly; the "citizens' army" of Bonaparte nicknamed the newcomers the "gentlemen" because of their superior smartness and discipline. Nevertheless, at the passage of the Tagliamento and the taking of Gradisca, Bernadotte and his proud division from the Rhine distinguished themselves for valour. After the campaign Bernadotte began a serious reading program, probably roused to do so by Bonaparte's superior knowledge of military science and history.

Though he was next slated to succeed Bonaparte in command of the army of Italy, both Bernadotte and the Austrians were shocked when he was named ambassador to Vienna. He was hardly a proper symbol of diplomatic reconciliation and he had no experience to fit him for the post. From January to April 1798 he did his soldier's best, but the mission ended on April 14 after a Viennese mob rioted against the embassy because of the hanging out of the tricolour.

Back in Paris the general and ambassador was free to enjoy for a time the delights of the salons of Mme. de Staël and Mme. Récamier, where he met the leading political and literary figures of the day. He also renewed acquaintance with the "pretty girl from Marseilles with the gay smile"—Désirée Clary—former fiancée of Joseph Bonaparte, of Napoleon and of Leonard Duphot. Her sister Julie had married Joseph Bonaparte, so that when Bernadotte married Désirée, Aug. 17, 1798, he came into the fringes of the Bonaparte clan.

In the fall of 1798 Bernadotte commanded the army of Mayence and arranged peace with Hesse-Darmstadt. He rejected the offer of command over the army of Italy because he considered the troops insufficient—as events proved them to be. He likewise refused the offer from Paul Barras to lead a *coup d'état* to force reconstitution of the Directory. In July 1799 the directors made him minister of war at a critical point in the fortunes of France. For ten weeks he applied his restless energy to problems of organization, recruiting and supply, but his growing fame and his constitutional scruples irritated Emmanuel-Joseph Sieyès, who engineered his removal. Bernadotte was thus out of office when Bonaparte returned from Egypt. Bonaparte asked his old colleague to join in his coup, but Bernadotte refused, promising only that he would take no initiative in opposition. On the success of the coup d'état of the 18th Brumaire, Bernadotte and Désirée went into brief hiding. He had been the most probable leader of the forces wishing to defend the Directory, but had passed up the chance to act by refusing to assume responsibility. Bernadotte was soon reconciled to the new regime, and from 1800 to 1810 was closely associated with the empire building of Napoleon, active in campaigns and administration, but repeatedly suspect because of his independent attitude and his connections with the opponents of the emperor. Bonaparte "absorbed" the Gascon general, as he did many of the potential opposition, by giving him position and prestige in the new regime.

Bernadotte became a councillor of state, and commander of the army of the west. He expected to defend Brittany from an attack by England, but found his job to be largely suppression of rebellion. Upon returning to Paris in the winter of 1801 he retired to Plombières because of suspicion directed against him on account of the Rennes plot. He was one of two or three generals most likely to be raised to high power if anything happened to Bonaparte; his unwillingness to co-operate in the Brumaire coup was well known; inevitably his name was discussed in connection with each successive plot against first consul or emperor. No evidence has been found to link him with any real plot, though it is clear that he would have favoured constitutional legislative action to limit the power of the first consul or even to overthrow him. Bonaparte was angry and suspicious and in Jan. 1803, in order to get Bernadotte out of the country, appointed him minister to the United States. While waiting to sail Bernadotte got wind of approaching war between France and England, so returned to Paris for an active military post. War was delayed and Bernadotte remained inactive in Paris for a year. Then Napoleon made himself emperor and Bernadotte declared full loyalty to him, having decided that nothing else was possible. He was named one of the 18 marshals of France (May 19, 1804) and early in June left for his new post as governor of Hanover. Here he was both military commander and civil administrative officer; in the combined capacity he showed executive skill and an ability to win the affection and respect of the citizenry. He showered privileges on the University of Göttingen and attempted in tax policy to ease the load of the poor and transfer the burden to the wealthy, including nobility and church. Here he began also to accumulate his small fortune, with "gifts" of 300,000 francs from Hanover and 200,000 francs from Bremen.

In 1805 the war with Austria became active and Bernadotte was ordered in August to lead his forces to Würzburg. He was given command of the I corps, including the Bavarian army. Difficulties with roads and boats and the inefficiency of the Bavarian forces delayed his march toward Vienna and brought reproaches from the emperor. Extraordinary marches brought the I corps to Austerlitz, where it occupied the centre. It played a relatively small role in the battle, partly because its cavalry had been transferred to Murat just before the battle. Bernadotte was annoyed, but Napoleon seemed pleased with him on this occasion. The next task given him (Feb. 19, 1806) was the occupation of Ansbach.

In accord with the imperial policy of naming outstanding generals to the new nobility, Bernadotte was made prince of Ponte Corvo, June 5, 1806. Ponte Corvo was an enclave of 5,600 inhabitants within the territory of the kingdom of Naples.

In October 1806 Bernadotte commanded a strengthened I corps of 15,000 to 21,000 men, including a French division under Pierre Dupont de L'Étang. Bernadotte did not participate actively in the conflicts at Jena or Auerstadt, and was blamed by Napoleon for not being where he should have been. Real responsibility for his absence rests upon Napoleon's unawareness of the Prussian position and upon the vagueness and indirectness of the orders of Marshal Louis Berthier, chief of staff. This in turn may have been caused by Berthier's personal antagonism to Bernadotte. After the battle Napoleon needed a scapegoat and used Bernadotte for the purpose. That he had no fundamental complaint is evidenced by the enlarged responsibility given to Bernadotte two months later—command over three corps which made up the left wing in the Polish campaign. In the meantime Bernadotte showed unusual energy and skill in the pursuit of the Prussians, especially at Halle and in the attack on Lübeck (where some 1,000 Swedish prisoners were taken, and tactful handling of whom was to pay dividends later). By tactics of speed and daring Bernadotte led his troops to a victory over the Russians at Mohrungen (Jan. 25, 1807), but missed the action at Eylau because of the capture of his orders. On June 5 he was wounded by a shot in the neck, and this kept him from the battle of Friedland.

On July 14, 1807, Bernadotte was named governor of the occupied Hanseatic cities. Again he was both administrator and commander, and asssumed the position of a viceroy. Soon he was scheduled to lead a combination of German, French and Spanish troops in an attack on Sweden. The emperor, who may not have intended the threat seriously, required a peculiar distribution of the troops. The total result was that the Spanish contingent deserted en masse and was carried off by English ships (Aug. 1808). The expedition against Sweden was abandoned, and French military power was once more directed against Austria. Bernadotte was ill at the beginning of the campaign with his recurrent blood-spitting. Further difficulties with Chief of Staff Louis Alexandre Berthier, and the inclusion in his IX corps of the ill-prepared Saxon allies combined with his illness to make him beg for release from service. Napoleon disregarded these appeals and Bernadotte organized his forces and proceeded with the campaign, commanding mostly allied troops, with few French. In the decisive battle at Wagram, Dupas' division was withdrawn without Bernadotte's knowledge and the marshal found himself with

depleted strength at the centre of the Austrian attack; in killed, wounded and missing he lost one-third of his soldiers and was forced to retire from the town of Wagram. As compensation for his bitterness and disappointment he issued on July 8, 1809, a bombastic order of the day exaggeratedly praising the skill and courage of the Saxon forces. Shortly before the battle he had stretched his authority to accede to an armistice for the Swedes. On July 10, perhaps partly as a penalty for these acts, the IX corps was dissolved, and Bernadotte was allowed to return to Paris "for reasons of health" but obviously in deep disfavour.

Bernadotte was therefore in Paris when word arrived (July 29, 1809) of the threatening British invasion at Walcheren. He offered his services, but the ministers, not clear as to his status, hesitated to put him in command. A despatch from Napoleon then ordered them to send Bernadotte if he was at hand. It is clear evidence of the emperor's confidence in the ability of the marshal despite their recent differences. Bernadotte went north immediately and ably organized the defense, though disease rather than force of arms proved the undoing of the British expedition. When the danger had disappeared and Bernadotte returned to Paris late in September political suspicions still surrounded him, and the minister of war tried to force him to go at once to a health resort—or presumably anywhere far from Paris. Bernadotte insisted on his right to live where he pleased, but yielded to an order to go to the emperor's headquarters in Vienna, where he remained Oct. 9–21, 1809. He then returned to Paris.

In the midst of this shadow and uncertainty came the dramatic call to a new life as crown prince and heir to the throne of Sweden. In 1809 Sweden had lost Finland to Russia; a palace revolution had overthrown King Gustav IV Adolf, and put on the throne the aged, childless Charles XIII, with the Danish Christian August as elected crown prince. In June 1810 the prince suddenly died, and Sweden, at the nadir of her fortunes, was forced again to seek a man to pilot the state and to be ready to succeed the ruler. It was natural to seek at least the advice of the master of Europe, then at the pinnacle of his power. Hence a delegation was despatched to Napoleon, but the emperor's peculiar reluctance to exert influence in this affair soon placed the initiative in the wholly unauthorized hands of baron Otto Mörner. Mörner was a young Swedish patriot who knew of Bernadotte's military career, his administration of Hanover and the Hansa towns, and his charitable treatment of Swedish prisoners. He contacted the marshal-prince and aroused his interest, then gained support from a few other Swedes in Paris. On his return to Sweden the government arrested him, but the fire had been lighted. The delegates to the special *Riksdag* in Örebro were influenced by the prince's military reputation and by the knowledge that his fortune would bolster the feeble Swedish *Riksbank*. Previous candidates were abandoned at the eleventh hour, and on Aug. 21, 1810, Bernadotte was elected crown prince. On Oct. 20 he accepted the Lutheran faith and landed in Sweden, there to establish the only enduring dynasty of the Napoleonic regime. Continuity in Sweden was maintained by his adoption as son by Charles XIII, and both king and queen were quickly charmed by the new heir, who took the name of Carl Johan (Charles John). The crown prince at once assumed actual leadership of the government and acted officially as regent during the prolonged illness of the king.

Foreign policy was of necessity the chief concern of Bernadotte's first years in Sweden. The majority of the people hoped for the reconquest of Finland and expected this to come by alliance with France. But a small group in the government looked instead to an annexation of Norway. Bernadotte himself, with vision undistorted by hereditary hatred of Russia, felt that any attempt to wrest Finland from the vast empire to the east would but perpetuate war and lead to the complete ruin of Sweden. Norway seemed to him a natural geographic and cultural unit with Sweden; he therefore bent every energy to make the Swedes forget Finland and build a peninsular Scandinavian state. He was guided also by three convictions: a belief in the inevitability of Napoleon's collapse; the idea that Sweden's economy demanded close ties with Great Britain and the smashing of the continental system; his personal need to achieve something for Sweden which would establish him and his family in power. Napoleon failed to deprive his ex-marshal of any opportunity to reorient Swedish policy, and on the heels of Bernadotte's departure sent a demand that Sweden declare war on Britain; Swedish Pomerania must cease to serve as a leak in the "continental system." In Nov. 1810 Sweden had no choice, but she declared war with her fingers crossed and fought it with her hands folded, in a tacit understanding with the English that there would be no shooting. Napoleonic annoyance at this state of affairs led at last to the sudden French occupation of Swedish Pomerania in Jan. 1812.

This attack on Swedish territory was all that was needed to dissipate the Francophile Swedes and win approval for Bernadotte's policy. Immediately negotiations began with Alexander of Russia for an alliance against Napoleon. This was concluded in April 1812, and in August Bernadotte and Alexander met in cordial conference at Åbo (Turku), Finland. Alexander pledged to send 35,000 men to help Bernadotte conquer Norway from Denmark, and Bernadotte pledged that as soon as this aim was accomplished he would lead an army to the continent to aid Russia against Napoleon. Russia at the cost won the friendship of its age-old enemy at a critical moment, and Sweden won the first ally for her major political shift. Through the coming months, while the French were staggering back from the disaster of the Moscow campaign, Bernadotte tried to gain other allies. His services were so eagerly desired that Britain (March 1813) and Prussia (April 1813) signed the clauses hateful to them guaranteeing Sweden possession of Norway, and Britain granted a generous subsidy. Austria held aloof. The allies then brought combined pressure on Bernadotte to forego his right to get Norway at once and aid in the great campaign against Napoleon. Bernadotte agreed, and an extra war with Denmark was thus postponed. But the crown prince came to distrust the good faith of his allies, and antagonisms grew.

Bernadotte landed 30,000 men at Stralsund in May 1813, but withheld them from action because the promised Russian and Prussian troops had not yet been sent him. Russia and Prussia made a ten weeks' armistice with Napoleon on June 4 and all action was delayed. In the interim misunderstandings were alleviated, and at the general conference at Trachenberg in July Bernadotte mapped out what came to be the basic plan of campaign which led to Leipzig. The foreign contingents were given to Carl Johan, who became commander of all the forces in north Germany, the right wing of the sweeping semicircular offensive. Fighting was resumed on Aug. 17, 1813, and on Aug. 23 he disposed his forces for the defeat of Oudinot at Grossbeeren, Germany. The Prussians bore the brunt of battle and blamed Bernadotte for sparing his Swedes—which he frankly did. He considered the war in north Germany a primarily Prussian concern; he did not share the desire of the Germans to exterminate all Frenchmen; and he felt the need to save his Swedes for the war with Denmark—he therefore would not waste them. Hence at the battle of Dennewitz, Sept. 6, there was the same skilful and successful disposition of troops, and the Prussians again did the lion's share of fighting.

Gradually now the armies converged toward Leipzig, where on Oct. 16–19 was fought the decisive Battle of the Nations. Here again, though his preliminary movements were above reproach, he showed a reluctance to come to direct grips with the French. Obviously he could not afford to risk an allied defeat, yet he hoped that the other armies could accomplish the common object. Though he was not present the first day of the battle, his artillery took a prominent part on the second day (the 18th) and the Swedish infantry joined battle on the 19th.

After the battle at Leipzig Bernadotte decided that French defeat was assured and that he had better collect on the unrealized promises of his allies. On Oct. 29 he turned his armies north and in a rapid but unspectacular campaign forced Denmark to sue for peace. In the treaty of Kiel (Jan. 14, 1814) King Frederick VI of Denmark signed over Norway to the Swedish crown (the transfer did not include the overseas possessions). Swedish control was far from being established in Norway, but the insistence and threats of the allies could be no longer disregarded—Bernadotte had to move toward France.

Nevertheless, the army of the north got only to the Netherlands, and Bernadotte's headquarters were long in Liége. He seemed to move with leaden feet while the Austrians, the Russians and the eager Prussians battered Napoleon into abdication. Natural hesitancy to invade his homeland was heightened in Bernadotte's case by an irresistible ambition: to become king or "protector" in France on the overthrow of the emperor. The tsar encouraged the idea and friends such as Mme. de Staël and Benjamin Constant urged it; ten years earlier he had been a logical choice for leadership by the opposition—why not now? He failed to realize how completely he was alienated from the French people. He failed to appreciate also that the victorious allies would not tolerate another military man at the head of the French state. Furthermore, he would not risk his comfortable position in Sweden by a bold stroke which might leave him with nothing. Hence his dream faded into thin air, and his brief visit to Paris after the armistice was far from glorious.

Difficulties in the north recalled him to duty. The Norwegians refused to recognize the treaty of Kiel: the king of Denmark was also king of Norway, but he had no right to transfer sovereignty. Some Norwegians desired union with Sweden, but most preferred to attempt independence. An assembly drew up the constitution of Eidsvold (May 17, 1814) and chose the Danish *Statholder* Christian Frederick as king. Bernadotte blamed Danish intrigue for the Norwegian opposition but hastened north determined to conquer the country directly.

With the reluctant but unwavering support of his allies he conducted an efficient and almost bloodless campaign. On Aug. 14 the Norwegians signed the convention of Moss and within the next few weeks arrangements were worked out which preserved the essential liberal principles of the Eidsvold constitution, the only real change being that which required that the king be the king of Sweden. At a time when military force could have established, temporarily at least, any regime it wished, it is significant that Bernadotte insisted on a humane and decidedly democratic settlement. Future conflicts of authority and opinion between parliament and king and between Norway and Sweden were often severe, but obviously 1814 definitely set Norway on the road to the complete independence which it realized in 1905. From the standpoint of Bernadotte and the Swedes much had been accomplished: retirement from Pomerania and from Finland took Sweden out of two areas of conflict; the connection with Norway prevented that land from being used again by Denmark as a place

from which to attack Sweden in the back. The long era of peace in the north from 1814 to 1940 is in itself evidence of the farsightedness of Bernadotte's "policy of 1812."

The 30 years following 1814 were fruitful ones for Bernadotte and for the kingdoms of Sweden and Norway, though they brought the inevitable tensions of a changing social, economic and political life. Bernadotte's ties with his old homeland were gradually cut. Prince Oscar, Bernadotte's only child (born 1799), had come to Sweden with his mother in 1811 (January) and was reared as a Swede. Désirée, however, had returned to Paris and did not come to Sweden to stay until 1823, on the occasion of Prince Oscar's betrothal and marriage (to Princess Josephine, daughter of Eugene de Beauharnais, granddaughter of the king of Bavaria). Through this marriage and its issue the Bernadotte dynasty was destined to continue in Sweden, long-lived and prolific. Though actually the most influential figure in the state from 1810 on, Bernadotte did not acquire the royal title until Feb. 5, 1818, upon the death of Charles XIII.

Having achieved the great goal of his foreign policy, the aim of Bernadotte after 1814 was to retain his position. During the period of the Congress of Vienna there were those who thought that the parvenu prince should be sacrificed to the principle of legitimacy. Prince Clemens W. N. Lothar von Metternich, Louis XVIII, and later Charles X of France were hostile, and the sons of the deposed Gustav IV Adolf were potential troublemakers. But the friendship of Tsars Alexander and Nicholas, and the support of the British government, both based upon recognition of Bernadotte's services and the legality of his position, left his status undisturbed. During the "Hundred Days" of 1815 Bernadotte watched events with keen interest, but avoided involvement.

The dispute with Denmark over the debt settlement and the conflict with Russia over the Norwegian-Russian frontier were arranged by compromise, and relations with Russia were maintained on a basis of mutual respect—plus watchfulness. Toward Britain the former French marshal changed his attitude when he changed his responsibilities, for he recognized the vital importance to Sweden and Norway of British trade and of the British navy.

A man trained for the battlefield and habituated to command inevitably had some difficulties adjusting himself to the procedure of councils and parliaments. His republican ideals and his common sense had many times to check his autocratic tendencies and his feeling that he alone was right. His failure to learn Swedish made his work more difficult and his mind more suspicious. He wanted to control things himself. Hence he tried to strengthen the merely suspensive veto he had over the legislation of the Norwegian *Storting*, and he exercised a conservative influence in Sweden. Yet when the opposition was really strong he knew how to yield or to compromise. His experience, his knowledge and his magnetic personal charm gave him a power in the state far outweighing that of any of the statesmen of the north in his day; his conscientious attention to the duties of kingship gave him a real mastery over the affairs of state, and won him the admiration and love of the common people.

Norway resented the method by which union had been achieved, and bitter internal controversies arose over questions like payment of the national debt, the celebration of May 17 (the Eidsvold constitution) and the abolition of the nobility. On Norway's responsibility to pay the agreed share of the Danish debt Bernadotte was adamant and even threatened the use of the military to force submission. On the questions of May 17 and the abolition of the nobility he yielded with fear and ill grace to the will of the Norwegian people. Again and again in such cases he would defy and threaten, then adapt himself to necessity. His impulsive gasconades led many both then and since to think of him as emotionally unstable. But always, though bold in talk, he was cautious and farsighted in action. Through royal yielding to pressures which were really strong the democratic processes and forces steadily matured.

Bernadotte was keenly interested in the welfare of the people as a whole and provided a stimulating though paternalistic leadership. He encouraged the founding of the Academy of Agriculture in 1811, was largely responsible for the rebuilding of the great library at the University of Uppsala, and for the spread of popular education. When he first went north he feared that "cognac would be the ruin of the Swedish people" and in the 1830s was able to give strong support to Per Wieselgren and the temperance movement. He likewise promoted medical education and the physical education program of P. H. Ling. National finance was one of his primary interests and he vigorously supported such projects as Platen's famous Göta canal.

Opposition to the king's autocratic methods and dominating position in Swedish life led to demands for his abdication in the late 1830s, and to some republican agitation. But he rode out the storm in Sweden as he had already done in Norway, and at the jubilee in 1843 his peoples were united in sincere expressions of admiration and gratitude to the "grand old man" of the north. When he died, aged 81, March 8, 1844, he left two kingdoms vastly stronger, more prosperous and more populous than in 1810, and a new dynasty firmly entrenched.

CHARLES XV. (1826–1872), king of Sweden and Norway, eldest son of Oscar I., king of Sweden and Norway, and Josephine Beauharnais of Leuchtenberg, was born on May 3, 1826. On June 19, 1850, he married Louisa, daughter of Prince Frederick of the Netherlands. He became regent on Sept. 25, 1857, and king on the death of his father (July 8, 1859). His reign was remarkable for its manifold and far-reaching reforms. Sweden's existing communal law (1862), ecclesiastical law (1863) and criminal law (1864) were enacted. Charles XV. also materially assisted D. Geer (*q.v.*) to carry through his memorable reform of the diet in 1865. Charles was a warm advocate of "pan-Scandinavianism" and the political solidarity of the three northern kingdoms, and his enthusiasm led him to give half promises of help to Denmark on the eve of the war of 1864. In view, however, of the unpreparedness of the Swedish army and the absence of support from any of the powers, Charles was forced to observe a strict neutrality. He died at Malmö on Sept. 18, 1872. Charles XV. enjoyed an unusual degree of popularity in both his kingdoms. He was a amateur painter and his *Dikter* show him to have been a true poet. He left one child, a daughter, Louisa Josephina Eugenia, who in 1869 married the crown prince Frederick of Denmark.

CHARLES (KARL ALEXANDER) (1712–1780), prince of Lorraine, the youngest son of Leopold, duke of Lorraine, and grandson of Charles V., duke of Lorraine (*see* p. 289), was born at Lunéville on Dec. 12, 1712. After his elder brother Francis, the duke, had exchanged Lorraine for Tuscany and married Maria Theresa, Charles became an Austrian officer, and he served in the campaigns of 1737 and 1738 against the Turks. At the outbreak of the Silesian wars in 1740 (*see* AUSTRIAN SUCCESSION, WAR OF THE) the queen made her brother-in-law a field marshal, and in 1742 Charles encountered Frederick the Great for the first time at the battle of Chotusitz (May 17). He conducted the successful campaign of 1743 against the French and Bavarians. He married, Jan. 1744, Marianne of Austria (died in 1744), sister of Maria Theresa, who made them jointly governors-general of the Austrian Netherlands. When the war broke out afresh, Charles, at the head of the Austrian army on the Rhine, crossed that river, but on Frederick's resumption of the Silesian war he hurried to Bohemia, whence, aided by the advice of the veteran field marshal Traun, he quickly expelled the Prussians. He took the field again in 1745 in Silesia, but this time without the advice of Traun, and he was twice severely defeated by Frederick, at Hohenfriedberg and at Soor. Subsequently, as commander-in-chief in the Low Countries he received, at Roucoux, a heavy defeat at the hands of Marshal Saxe. His government of the Austrian Netherlands during the peace of 1749–56 was marked by many reforms. After the first reverses of the Seven Years' War (*q.v.*), Maria Theresa called Charles again to the supreme command in the field. The campaign of 1757 opened with Frederick's great victory of Prague, and Prince Charles was shut up with his army in that fortress. In the victory of the relieving army under Daun at Kolin Charles had no part, but he won the battle of Breslau, and great enthusiasm was displayed in Austria over the victory, which seemed to be the final blow to Frederick. But soon afterwards the king of Prussia routed the French at Rossbach, and, swiftly returning to Silesia, he inflicted on Charles the complete and crushing defeat of Leuthen (Dec. 5, 1757). A mere remnant of the Austrian army reassembled after the pursuit, and Charles was relieved of his command. For a year thereafter Prince Charles acted as a military adviser

Vienna, he then returned to Brussels, where he continued to govern till his death on July 4, 1780, at the castle of Tervueren.

See L. Percy, *Charles de Lorraine et la cour de Bruxelles sous le règne de Marie Thérèse* (1903).

CHARLES (1421–1461), prince of Viana, sometimes called Charles IV., king of Navarre, was the son of John, afterwards John II., king of Aragon, by his marriage with Blanche, daughter of Charles III. of Navarre. Both his grandfather Charles and his mother, who ruled over Navarre, had bequeathed this kingdom to Charles, whose right had also been recognized by the Cortes; but when Blanche died in 1441 her husband John seized the government. The ill-feeling between father and son was increased when in 1447 John took for his second wife Joanna Henriquez, a Castilian princess, who bore him a son, afterwards Ferdinand I., king of Spain. When Joanna began to interfere in the internal affairs of Navarre civil war broke out; and in 1452 Charles, although aided by John II., king of Castile, was taken prisoner. Released upon promising not to take the kingly title until after his father's death, the prince, again unsuccessful in an appeal to arms, took refuge in Italy with Alphonso V., king of Aragon, Naples and Sicily. In 1458 Alphonso died and John became king of Aragon, while Charles was offered Naples and Sicily. He declined these proposals, and having been reconciled with his father returned to Navarre in 1459. Aspiring to marry a Castilian princess, he was thrown into prison by his father; the Catalans rose in his favour, and John was obliged to yield. Charles was recognized as perpetual governor of Catalonia and heir to the kingdom, but he died on Sept. 23, 1461. Charles was a cultured prince; he translated the *Ethics* of Aristotle into Spanish (Saragossa, 1509) and wrote a chronicle of the kings of Navarre, *Crónica de los reyes de Navarra*, an edition of which, edited by J. Yangues y Miranda, was published at Pampeluna (1843).

CHARLES [KARL LUDWIG] (1771–1847), archduke of Austria and duke of Teschen, third son of the emperor Leopold II., was born at Florence (his father being then grand-duke of Tuscany) on Sept. 5, 1771. His youth was spent in Tuscany, at Vienna and in the Austrian Netherlands, where he began his career of military service in the war of the French Revolution. He commanded a brigade at Jemappes, and in the campaign of 1793 distinguished himself at the action of Aldenhoven and the battle of Neerwinden. In this year he became *Statthalter* in Belgium and received the army rank of lieutenant field marshal, which promotion was soon followed by that to *Feldzeugmeister* (master of ordnance). In the remainder of the war in the Low Countries he held high commands, and he was present at Fleurus. In 1795 he served on the Rhine, and in the following year was entrusted with the chief control of all the Austrian forces on that river. His conduct of the operations against Jourdan and Moreau in 1796 marked him out at once as one of the greatest generals in Europe. At first falling back carefully and avoiding a decision, he finally marched away, leaving a mere screen in front of Moreau; falling upon Jourdan he beat him in the battles of Amberg and Würzburg, and drove him over the Rhine with great loss. He then turned upon Moreau's army, which he defeated and forced out of Germany. For this campaign, one of the most brilliant in modern history, *see* FRENCH REVOLUTIONARY WARS. In 1797 he was sent to arrest the victorious march of Gen. Bonaparte in Italy, and he conducted the retreat of the over-matched Austrians with the highest skill. In the campaign of 1799 he was once more opposed to Jourdan, whom he defeated in the battles of Osterach and Stokach, following up his success by invading Switzerland and defeating Masséna in the (first) battle of Zürich, after which he re-entered Germany and drove the French once more over the Rhine. Ill-health, however, forced him to retire to Bohemia, hence he was soon recalled to undertake the task of checking Moreau's advance on Vienna. The result of the battle of Hohenlinden had, however, foredoomed the attempt, and the archduke had to make the armistice of Steyer. His popularity was now such that the diet of Ratisbon, which met in 1802, resolved to erect a statue in his honour and to give him the title of saviour of his country; but Charles refused both distinctions.

In the short and disastrous war of 1805 the archduke Charles commanded what was intended to be the main army, in Italy, but events made Germany the decisive theatre of operations, and the defeats sustained on the Danube neutralized the success obtained by the archduke over Masséna in the desperately fought battle of Caldiero. With the conclusion of peace began his active work of army reorganization, which was first tested on the field in 1809. As generalissimo of the army he had been made field marshal some years before. As president of the Council of War, and supported by the prestige of being the only general who had proved capable of defeating the French, he promptly initiated a far-reaching scheme of reform, which replaced the obsolete methods of the 18th century, the chief characteristics of the new order being the adoption of the "nation in arms" principle and of the French war organization and tactics. The new army was surprised in the process of transition by the war of 1809, of which Charles was commander in chief; yet even so it proved a far more formidable opponent than the old, and, against the now heterogeneous army which Napoleon controlled (*see* NAPOLEONIC CAMPAIGNS) it succumbed only after a desperate struggle. Its initial successes were neutralized by the reverses of Abensberg, Landshut and Eckmühl; but, after the evacuation of Vienna, the archduke won the great battle of Aspern-Essling (*q.v.*) and soon afterwards fought the still more desperate battle of Wagram (*q.v.*), at the close of which the Austrians were defeated but not routed; they had inflicted upon Napoleon a loss of over 50,000 men in the two battles. At the end of the campaign the archduke gave up all his military offices, and spent the rest of his life in retirement, except a short time in 1815, when he was governor of Mainz. In 1822 he succeeded to the duchy of Saxe-Teschen. The archduke Charles married, in 1815, Princess Henrietta of Nassau-Weilburg (d. 1829). He had four sons, the eldest of whom, the archduke Albert (*q.v.*) became one of the most celebrated generals in Europe, and two daughters, the elder of whom became queen of Naples. He died at Vienna on April 30, 1847.

The caution which the archduke preached so earnestly in his strategical works, he displayed in practice only when the situation seemed to demand it, though his education certainly prejudiced him in favour of the defensive at all costs. He was at the same time capable of forming and executing the most daring offensive strategy, and his tactical skill in the handling of troops, whether in wide turning movements, as at Würzburg and Zürich, or in masses, as at Aspern and Wagram, was certainly equal to that of any leader of his time, Napoleon only excepted. The campaign of 1796 is considered almost faultless. That he sustained defeat in 1809 was due in part to the great numerical superiority of the French and their allies, and in part to the condition of his newly reorganized troops. His six weeks' inaction after the victory of Aspern is, however, open to unfavourable criticism. As a military writer, his position in the evolution of the art of war is very important, and his doctrines had naturally the greatest weight. Nevertheless they cannot but be considered as antiquated even in 1806. Caution and the importance of "strategic points" are the chief features of his system. The rigidity of his geographical strategy may be gathered from the direction that "this principle is *never* to be departed from." Again and again he repeats the advice that nothing should be hazarded unless one's army is *completely* secure, a rule which he himself neglected with such brilliant results in 1796. In his tactical writings the same spirit is conspicuous. His reserve in battle is designed to "cover a retreat." The baneful influence of these principles was shown in the maintenance of Königgrätz-Josefstadt in 1866 as a "strategic point," which was preferred to the defeat of the separated Prussian armies; in the strange plans produced in Vienna for the campaign of 1859, and in the "almost unintelligible" battle of Montebello in the same year. The theory and the practice of the archduke Charles form one of the most curious contrasts in military history. In the one he is often unreal, in the other he displayed, besides great skill, a vivid activity which made him for long the most formidable opponent of Napoleon.

His writings were edited by the archduke Albert and his brother

the archduke William in the *Ausgewählte Schriften seiner Kgl. Hoheit Erzh. Karl v. Österreich* (1862; reprinted 1893, Vienna and Leipzig), which includes the *Grundsätze der Kriegskunst für die Generäle* (1806), *Grundsätze der Strategie erläutert durch die Darstellung des Feldzugs 1796* (1814), *Gesch. des Feldzugs von 1799* (1819)—the two latter invaluable contributions to the history of the war, and papers "on the higher art of war," etc. *See*, besides the histories of the period, F. J. A. Schneidawind, *Karl, Erzherzog v. Österr. und die österr. Armee* (Vienna, 1840) and *Das Buch vom Erzh. Karl* (1848); Ed. Duller, *Erzh. Karl von Österr.* (1845–47); H. von Zeissberg, *Erzh. CHARLES (*c.* 1319–1364), duke of Brittany, known as CHARLES OF BLOIS and CHARLES OF CHÂTILLON, was the son of Guy of Châtillon, count of Blois (d. 1342), and of Margaret of Valois, sister of Philip VI of France. In 1337 Charles married Joan the Lame of Penthièvre (d. 1384), daughter of Guy of Brittany, count of Penthièvre (d. 1331), and thus acquired a right to the succession of the duchy of Brittany. On the death of John III, duke of Brittany, in April 1341, his brother John, count of Montfort l'Amaury, and his niece Joan, wife of Charles of Blois, disputed the succession. Charles of Blois, sustained by Philip VI, captured John of Montfort, who was supported by King Edward III, at Nantes, besieged his wife Joan of Flanders at Hennebont and took Quimper and Guérande (1344). But next year his partisans were defeated at Cadoret, and in June 1347 Charles was himself wounded and taken prisoner at La Roche-Derrien. He was not liberated until 1356, when he continued the war against the young John of Montfort and perished in the battle of Auray, on Sept. 29, 1364. In his lifetime he had been held a saint and a thaumaturge by the people; and his grave and relics were venerated, and his cult developed. In 1904 his beatification was proclaimed by the Holy See.

See Monuments du procès de canonisation du bienheureux Charles de Blois, duc de Bretagne, 1320–64 (Saint-Brieux, 1921).

CHARLES, called THE BOLD or LE TÉMÉRAIRE (1433–1477), duke of Burgundy, succeeded his father, Philip the Good, in 1467, after taking his place during his last illness (April 12, 1465, to June 15, 1467); before this, his title was count of Charolais. Born at Dijon, French by his paternal ancestry, brought up in the French manner as a friend of the dauphin (afterward Louis XI of France) and married successively to his French cousins Catherine (d. 1446), daughter of Charles VII of France, and Isabella (d. 1465), daughter of Charles I of Bourbon, Charles did not become hostile to the French crown until he took over the government of his duchy. Then it pleased him to remember the foreign origins of Isabella of Portugal, his mother, who was John of Gaunt's granddaughter, and of his third wife, whom he was to marry in 1468, Margaret of York, a sister of Edward IV of England. Throughout his reign, Charles aimed at making the Burgundian territories independent of France.

Charles was almost entirely successful until 1474. He succeeded in extending his possessions, in organizing them as a state and in freeing them from the French crown. Much annoyed by Louis XI's repurchase of the towns on the Somme which had been temporarily ceded to Philip the Good by the treaty of Arras (1435), he entered upon his lifelong struggle against Louis and became one of the principal leaders of the League of the Public Weal. After the battle of Montlhéry (July 16, 1465), he forced Louis to restore to him the towns on the Somme and to promise him the hand of his daughter Catherine of France, as his third wife, with Champagne as dowry. But when Louis encouraged Dinant in its revolt against Burgundy, Charles sacked it (1466); and the Liégeois, whom the French were continually inciting to revolt, were defeated in battle and deprived of their liberties after the death of Philip the Good (1467). Louis now tried negotiations with Charles at Péronne (Oct. 1468). There, in the course of the discussions, Charles was informed of a fresh revolt of the Liégeois, secretly fomented by Louis. Looking on Louis as a traitor, Charles nevertheless treated with him but at the same time forced him to assist in quelling the revolt; the town was destroyed and the inhabitants were massacred. The truce was not lasting. Louis cited Charles to appear before the *parlement* of Paris and seized some of the towns on the Somme. The duke retaliated by invading Normandy and the Île-de-France, ravaged the country as far as Rouen, but failed in an attack on Beauvais (1471–72). He decided to wait, before renewing his attempt, for the conclusion of an alliance with Edward IV and for the solution of the problem relative to the eastern border of his states.

Charles wished to extend his territories as far as the Rhine and to make them into a single unit by acquiring the lands between Burgundy, Luxembourg and the Netherlands. He lost no opportunity: he purchased the county of Ferrette, the landgraviate of Alsace and some other towns from the archduke Sigismund of Austria in 1469; he compelled the old duke Arnold of Gelderland to transfer his estates to him in 1473; and he set nominees of his own in certain other places and wished to do the same at Cologne, where he intended to install a garrison as it was both an important centre of trade and an imperial electorate (1469–74). To achieve his territorial aims, it only remained for him to subdue the Swiss cantons and to get Lorraine from René II (René of Vaudémont).

Meanwhile Charles had been reorganizing his army and the administration of his territories. Statutes promulgated at Thionville (1473) instituted companies of four squadrons, at his expense, and made rules for discipline and tactics; Charles also had many excellent guns cast. He hired mercenaries and took many Italian *condottieri* into his service. Intending to centralize the government, he created by statute a single *chambre des comptes*, a *chambre du trésor* to survey the administration of the domain and a *chambre des généraux* to control the collection of taxes. He exacted very heavy taxes indeed from the *états-généraux*, which became a regular institution in his territories. Moreover, he established the *grand conseil* at Malines, with jurisdiction to supersede that of the *parlement* of Paris, which he no longer recognized.

It remained for Charles to acquire a royal title. For a short time he entertained designs on the imperial crown; but this he renounced. On the other hand, he believed that he had persuaded the emperor Frederick III, in the course of conversations at Trèves (Trier), to agree to crown him king. The royal insignia were ready and the ceremony arranged, when Frederick precipitately fled by night (Sept. 1473). He probably was suspicious of the ambitious Charles.

In less than three years, Charles's dream vanished. The crown had slipped through his fingers. He was obliged to give up his plan of taking the little town of Neuss, which he had unsuccessfully besieged for ten months (July 1474 to June 1475), from the citizens of Cologne. Moreover, the treaty of Picquigny (Aug. 29, 1475) concluded by Edward IV and Louis XI made certain the defection of his English ally. Attacked by René of Lorraine and his allies, Charles took Nancy in Nov. 1475; but in March and in June 1476, he was defeated by the Swiss, at Grandson and at Morat (*see* SWITZERLAND: *History*). Next October he lost Nancy. Then, on Jan. 5, 1477, a further battle was fought outside Nancy, and Charles himself was killed; his mutilated body was discovered some days later.

The fragility of his achievement is proved by its rapid disintegration during the minority of Mary, his daughter by Isabella of Bourbon. Yet Charles the Bold was not merely a belated representative of the chivalrous spirit; he was a man of wide knowledge and culture, already a prince of the Renaissance. His haste, his lack of adaptability and his obstinacy lost him much more than did his visionary approach and his boldness.

(MI. M.)

CHARLES (953–*c.* 992), duke of Lower Lorraine, was a younger son of the Frankish king Louis IV and thus a member of the Carolingian family. He received the duchy of Lower Lorraine from the emperor Otto II in 977; and he aided Otto in his struggle with King Lothair, with whom however he became reconciled after Otto's death. On the death of his nephew Louis V (987), Charles made an effort to secure the Frankish crown. Hugh Capet, however, was the successful candidate, and war broke out. Charles had gained some successes and had captured Reims (989), when in 991 he was treacherously seized by Adalberon (*q.v.*), bishop of Laon, and handed over to Hugh. Imprisoned with his wife and his younger children at Orléans, Charles did not long survive his humiliation. His eldest son Otto, duke of Lower Lorraine, died *c.* 1012.

See F. Lot, *Les derniers Carolingiens* (Paris, 1891).

CHARLES II (d. 1431), duke of Lorraine, called THE BOLD is sometimes referred to as Charles I. A son of Duke John I he succeeded his father in 1390; but he neglected his duchy and passed his life in warfare. He died on Jan. 25, 1431, leaving two daughters, one of whom, Isabella (d. 1453) married René I of Anjou (1409–80), king of Naples, who succeeded his father-in-law as duke of Lorraine.

CHARLES III (1543–1608), called THE GREAT, duke of Lorraine was a son of Duke Francis I (d. 1545) and a descendant of René of Anjou. Born at Nancy on Feb. 18, 1543, he was brought up at the court of Henry II of France, marrying Henry's daughter Claude in 1559. He took part in the wars of religion in France and was a member of the Holy league. The duke, who was an excellent ruler of Lorraine, died at Nancy on May 14, 1608. He had three sons: Henry (d. 1624) and Francis (d. 1632), who became in turn dukes of Lorraine, and Charles (d. 1607), bishop of Metz and Strasbourg.

CHARLES IV (1604–1675), duke of Lorraine and Bar, born at Nancy on April 5, 1604, became duke in 1624 by right of his wife Nicole, his uncle Henry II's daughter and heiress, whom he had married in 1621. As, however, both he and his father, Francis of Vaudémont, wished to abolish the female right of succession to the duchy, Francis was proclaimed to be Henry's rightful successor in Nov. 1625; then he abdicated in Charles's favour after a few days' reign. To counter French interventions in the affairs of Lorraine, Charles in 1627 began negotiations with England against France, while at the same time supporting the Holy Roman emperor against the Swedes (*see* THIRTY YEARS' WAR), and from 1629 he took up the cause of Gaston of Orléans against Louis XIII. Subdued by the French in 1632 (treaty of Liverdun, June 26) and again in 1633 (when he had to cede Nancy), Charles abdicated on Jan. 19, 1634, in favour of his brother, Cardinal Nicolas Francis (who left the church and married Nicole's sister Claude), and entered the imperial service; Charles was banished from the kingdom of France. He took part in the battle of Nordlingen and in successive campaigns along the French eastern frontier. The treaty of Saint Germain (March 29, 1641) restored Lorraine and Bar to him, shorn of several towns and fortresses; but as he proved treacherous again, the duchies were again occupied and declared neutral (June 1644). Returning then to the imperial service, Charles transferred himself to the Spanish after the peace of Westphalia, from which he was excluded. In 1652 he made two incursions into France on behalf of the Fronde (*q.v.*), but in 1654 the Spaniards arrested him for intriguing with Cardinal Mazarin. Imprisoned at Antwerp and Toledo till the treaty of the Pyrenees (1659), he recovered his duchies by the treaty of Vincennes (Feb. 28, 1661) and then arranged to sell them to Louis XIV by the treaty of Montmartre (Feb. 6, 1662), which was however annulled by the treaty of Vincennes (Aug. 31, 1663). French troops overran Lorraine yet again in 1670, and Charles was severely defeated by Marshal Turenne at Sinzheim in 1674. In 1675, however, he defeated François de Créquy at Konzer Brücke (Aug. 11) and captured him at Trier (Sept. 6); but on Sept. 18 he died in a village near Birkenfeld. Charles Henry of Vaudémont (1649–1723) was his illegitimate son by Béatrix de Cusance.

A brave and skilful soldier, Charles was an impolitic statesman, missing good opportunities and paying always a heavy price to redeem his acts of rashness.

BIBLIOGRAPHY.—R. Parisot, *Histoire de Lorraine*, vol. ii (Paris, 1922); F. des Robert, *Campagnes de Charles IV . . . 1638–48*, 2 vol. (Paris, 1883–88), *Charles IV et Mazarin* (Nancy, 1899).

CHARLES V (1643–1690), duke of Lorraine and Bar, was born in Vienna on April 3, 1643, the son of Charles IV's brother Nicolas Francis. Emperor Leopold I gave him a regiment in 1664, and he distinguished himself at the battle of Saint Gotthard. He was a candidate for the Polish crown in 1668–69 and again, when the French were occupying Lorraine, in 1674. Recognized by all save France as his uncle's heir in 1675, he was never to possess his duchies. Promoted field marshal by the emperor in 1675, he took Philippsburg in 1676. He married Eleonora Maria, dowager queen of Poland and the emperor's sister, in 1678. The peace of Nijmegen offered him his duchies under conditions that he rejected. In 1683, with a weak imperial army, he opposed the Turkish advance on Vienna. Two months after the Turks had invested the city, John Sobieski's Poles and the Bavarian and Saxon contingents arrived to reinforce Charles, and on Sept. 12 the Christians routed the enemy and raised the siege. Advancing into Hungary, Charles besieged Buda (1684), stormed Neuhäusel (1685), finally took Buda (1686) and, in Aug. 1687, won the great victory of Mohács. Transferred to the Rhine for the War of the Grand Alliance, Charles took Mainz and Bonn in 1689 but died suddenly at Wels on April 18, 1690. As well as the military genius that made him one of Louis XIV's most respected adversaries, he had qualities of statesmanship; but these he could not exert for the benefit of his duchies. At the peace of Ryswick (1697) Lorraine and Bar were assigned to his son Leopold Joseph Charles (1679–1729).

CHARLES II (CHARLES LOUIS DE BOURBON) (1799–1883), duke of Parma, succeeded his mother, Maria Louisa in the duchy of Lucca in 1824. He introduced economy into the administration, increased the schools, and in 1832 became a Protestant. In 1842 he returned to the Catholic Church and made Thomas Ward, an English groom, his prime minister, a man not without ability and tact. In 1847 he declared himself hostile to the reforms introduced by Pius IX. The Lucchesi demanded the constitution of 1805, promised them by the treaty of Vienna, and a national guard, but the duke, in spite of the warnings of Ward, refused all concessions. A few weeks later he sold his life interest in the duchy to Tuscany. On Oct. 17 Maria Louisa of Austria, duchess of Parma, died, and Charles Louis succeeded to her throne by the terms of the Florence treaty, assuming the style of Charles II. His administration of Parma was characterized by ruinous finance, debts, disorder and increased taxation, and he concluded an offensive and defensive alliance with Austria. After the outbreak of the revolution in 1848, he abdicated in April and left Parma in the hands of a provisional government, whereupon the people voted for union with Piedmont. Later Charles II issued an edict from Weistropp annulling the acts of the provisional government.

In May 1849 Charles confirmed his abdication, and was succeeded by his son CHARLES III (1823–54), who, protected by Austrian troops, placed Parma under martial law, inflicted heavy penalties on the members of the late provisional government, closed the university and instituted a regular policy of persecution. A violent ruler, a drunkard and a libertine, he was assassinated on March 26, 1854. At his death his widow, Louisa (1819–64), sister of the comte de Chambord, became regent during the minority of his son Robert (1848–1907), who was dispossessed when the duchy was annexed to the kingdom of Sardinia in 1860.

CHARLES (1270–1325), count of Valois, of Anjou and of Maine, third son of Philip III, king of France, was born on March 12, 1270. He received in appanage the four lordships of Crépy, La Ferté-Milon, Pierrefonds and Béthisy, which together formed the countship of Valois. A handsome man, a brilliant and generous knight, but an ambitious and needy prince, he was a pretender to many crowns and had the strange destiny to be "son of a king, brother of a king, uncle of three kings, father of a king, but never a king." In 1284 Martin IV, having excommunicated Peter III, king of Aragon, offered his kingdom to Charles; but the

campaign in Catalonia, by which Philip III attempted to conquer it for his son, was a disaster, and Philip died on his return. In 1290 Charles married Margaret, daughter of Charles II of Naples, and renounced his pretensions to Aragon in return for the counties of Anjou and Maine; his brother, Philip IV, gave him Alençon and Perche. Asked by Boniface VIII for his aid against the Ghibellines, Charles went to Italy in 1301, entered Florence and helped Charles of Naples to reconquer Calabria and Apulia from the house of Aragon, but failed in Sicily. Having married (1301) Catherine de Courtenay, a granddaughter of the eastern emperor Baldwin II, he tried to assert his rights to Byzantium. In 1308, on the death of Albert of Austria, he was a candidate for the western empire, with Philip IV's support; but Pope Clement V quashed his candidature in favour of Henry of Luxemburg. Despite these failures, Charles was a loyal servant of the French kings, particularly in war; he commanded their armies in Guienne (1295 and 1324) and in Flanders (1297, 1299, 1300, 1303, 1314, 1315); in 1300 he took Douai, Béthune and Dam and received the submission of Guy of Dampierre; and in 1304 he helped Philip IV win the battle of Mons-en-Pévèle. Under Louis X he headed the party of feudal reaction and was the main instrument of Enguerrand de Marigny's ruin. In 1316, at Louis's death, he tried unsuccessfully to be made regent. He died at Le Perray (Seine-et-Oise) on Dec. 16, 1325. He had been married three times and had 14 children. His eldest son, Philip, became king of France in 1328, the first of the royal house of Valois.

See Joseph Petit, *Charles de Valois* (Paris, 1900).

CHARLES, ELIZABETH (1828–1896), English author, was born at Tavistock on Jan. 2 1828, the daughter of John Rundle, M.P., and died at Hampstead on March 28 1896. In 1851 she married Andrew Paton Charles. Her best known book, *The Chronicles of the Schönberg-Cotta Family*, was published in 1862, and was translated into most of the European languages, into Arabic, and into many Indian dialects. Mrs. Charles wrote in all some 50 books, the majority of a semi-religious character.

CHARLES, JACQUES ALEXANDRE CÉSAR (1746–1823), French mathematician and physicist, was born at Beaugency, Loiret, on Nov. 12, 1746. From being a clerk in the ministry of finance, he turned to scientific pursuits, and became one of the most acute of physical researchers and inventors. He was the first, in 1783, to employ hydrogen for the inflation of balloons (*see* BALLOON), and about 1787 he anticipated Gay Lussac's law of the dilatation of gases with heat, which on that account is sometimes known by his name. He improved the Gravesand heliostat and the aerometer of Fahrenheit and invented a "thermometric hydrometer," a "goniometer by reflection" and many other ingenious physical devices. In 1785 he was elected to the Academy of Sciences, and subsequently he became professor of physics at the Conservatoire des Arts et Métiers. He died in Paris on April 7, 1823. His published papers are chiefly concerned with mathematical topics.

CHARLES, THOMAS (1755–1814), Welsh Nonconformist divine, was born at Longmoor, Carmarthenshire, on Oct. 14, 1755, and educated at Jesus college, Oxford, for the Church. He was ordained priest in 1782, and held some curacies in Somersetshire, but he resigned these in 1783 and returned to Wales. He had fallen under the influence of the Welsh revivalists before he went to Oxford, and had Methodist connections. He found no pulpit open to him in the Church in Wales, and joined the Calvinistic Methodists in 1784.

He had already begun to provide classes for poor children in Bala; he now held the classes in the chapel, and gradually began the system of Welsh Circulating Schools, on the model devised by Griffith Jones (d. 1761). By 1794 he had 20 travelling masters at work. In 1785 he had become the agent of the Sunday School Society in Wales; he secured supplies of Welsh Bibles from the S.P.C.K. and in 1801 alone nearly 3,000 were distributed. In 1802 he went to London to place Welsh requirements before the Religious Tract Society, and put his case so well that his friends decided to found a society for the publication and distribution of the Scriptures. This was the origin of the British and Foreign Bible Society. He stimulated similar educational movements in Ireland and Scotland. In 1810 he led the movement for the establishing of a regular ordained ministry in the Calvinistic Methodist connection, and, this work accomplished, returned to his task of fostering auxiliary Bible societies. He died on Oct. 5, 1814. Charles compiled the *Geiriadur Ysgrythyrol*, a biblical dictionary (4 vols. 1805–08), which has passed through many editions; he drew up the first definite constitution of the Welsh Methodists, and wrote many Welsh tracts. The first Welsh biography of Charles appeared in 1816. *See* W. Hughes, *Life and Letters of Thomas Charles* (Rhyl 1881), in which some of Charles's minor writings are reprinted.

CHARLES ALBERT (CARLO ALBERTO) (1798–1849), king of Sardinia (Piedmont), son of Prince Charles of Savoy-Carignano and Princess Albertine of Saxe-Courland, was born on Oct. 12, 1798, a few days before the French occupied Piedmont and forced his cousin, King Charles Emmanuel, to take refuge in Sardinia. In 1802 King Charles Emmanuel abdicated in favour of his brother, Victor Emmanuel I. On the fall of Napoleon in 1814 the Piedmontese court returned to Turin, and the king was anxious to secure the succession for Charles Albert, knowing that Austria meditated excluding him from it in favour of an Austrian archduke. He was summoned to Turin, given tutors to instruct him in legitimist principles, and on Oct. 1, 1817, married the archduchess Maria Theresa of Tuscany, who, on March 14, 1820, gave birth to Victor Emmanuel, afterwards king of Italy.

The Piedmontese government at this time was most reactionary, and had made a clean sweep of all French institutions. But there were strong Italian nationalists and anti-Austrian tendencies among the younger nobles and army officers, and the Carbonari and other revolutionary societies had made much progress. Their hopes centred in the young Carignano, whose agreeable manners had endeared him to all, and who had many friends among the Liberals and Carbonari. Early in 1820 a revolutionary movement was set on foot. Charles Albert no doubt was aware of this, but he never actually became a Carbonaro, and was surprised and startled when after the outbreak of the Neapolitan revolution of 1820 some of the leading conspirators in the Piedmontese army informed him that a military rising was ready and that they counted on his help (March 2, 1821). He induced them to delay the outbreak and informed the king, requesting him, however, not to punish anyone. On the 10th the garrison of Alessandria mutinied, and two days later Turin was in the hands of the insurgents, the people demanding the Spanish constitution. The king at once abdicated and appointed Charles Albert regent. The latter, pressed by the revolutionists and abandoned by his ministers, granted the constitution and sent to inform Charles Felix, who was now king, of the occurrence. Charles Felix, who was then at Modena, repudiated the regent's acts, accepted Austrian military assistance, with which the rising was easily quelled, and exiled Charles Albert to Florence. The young prince found himself the most unpopular man in Italy, for while the Liberals looked on him as a traitor, to the king and the Conservatives he was a dangerous revolutionist. At the Congress of Verona (1822) the Austrian chancellor, Prince Metternich, tried to induce Charles Felix to set aside Charles Albert's rights of succession. But the king was piqued by Austria's interference, and as both the grand-duke of Tuscany and the duke of Wellington supported him, Charles Albert's claims were respected. But it was not until he had signed a secret undertaking binding himself, as soon as he ascended the throne, to place himself under the tutelage of a council composed of the higher clergy and the knights of the Annunziata, and to maintain the existing forms of the monarchy (D. Berti, *Cesare Alfieri*, xi. 77, Rome, 1871), that he was allowed to return to Turin and forgiven.

On the death of Charles Felix (April 27, 1831) Charles Albert succeeded; he inherited a kingdom without an army, with an empty treasury, a chaotic administration and mediaeval laws. His first task was to set his house in order; he reorganized the finances, created the army, and started Piedmont on a path which, if not liberalism, was at least progress. In 1833 a conspiracy of the *Giovane Italia* society, organized by Mazzini, was discovered, and a number of its members punished with ruthless severity. The election in 1846 of Pius IX., who appeared to be a Liberal a

Italian patriot to some extent, reconciled the king to the Liberal movement, for it accorded with his religious views. On Oct. 30 he issued a decree granting wide reforms, and when risings broke out in other parts of Italy early in 1848, and further liberties were demanded, he was at last induced to grant the constitution (Feb. 8).

When the news of the Milanese revolt against the Austrians reached Turin (March 19) public opinion demanded that the Piedmontese should succour their struggling brothers; and after some hesitation the king declared war. But much time had been wasted and many precious opportunities lost. With an army of 60,000 Piedmontese troops and 30,000 men from other parts of Italy the king took the field, and after defeating the Austrians at Pastrengo on April 30, and at Goito on May 30, where he was himself slightly wounded, more time was wasted in useless operations. Radetzky, the Austrian general, having received reinforcements, drove the centre of the extended Italian line back across the Mincio (July 23), and in the two days' fighting at Custozza (July 24–25) the Piedmontese were beaten, forced to retreat and to ask for an armistice. The revolutionary movement throughout Italy was breaking down, but Charles Albert felt that while he possessed an army he could not abandon the Lombards and Venetians, and determined to stake all on a last chance. On March 12, 1849, he denounced the armistice and took the field again with an army of 80,000 men. He gave the chief command to the Polish general Chrzanowski, but he was completely out-generalled and defeated at La Bicocca near Novara on the 23rd. The Piedmontese fought with great bravery, and the unhappy king sought death in vain. After the battle he asked terms of Radetzky, who demanded the occupation by Austria of a large part of Piedmont, and the heir to the throne as a hostage. Thereupon, feeling himself to be the obstacle to better conditions, Charles Albert abdicated in favour of his son Victor Emmanuel. That same night he departed alone and made his way to Oporto, where he retired into a monastery and died on July 28, 1849.

Charles Albert was not a man of first-rate ability; he was of a hopelessly vacillating character. Devout and mystical to an almost morbid degree, hating revolution and distrusting Liberalism, he was a confirmed pessimist, yet he had many noble qualities: he was brave to the verge of foolhardiness, devoted to his country, and ready to risk his crown to free Italy from the foreigner. To him the people of Italy owe a great debt, for if he failed in his object he at least materialized the idea of the Risorgimento in a practical shape, and the charges which the Republicans and demagogues brought against him were monstrously unjust.

Bibliography.—Besides the general works on modern Italy, *see* the Marquis Costa de Beauregard's interesting volumes *La Jeunesse du roi Charles Albert* (1899) and *Novare et Oporto* (1890), based on the king's letters and the journal of Sylvain Costa, his faithful equerry, though the author's views are those of an old-fashioned Savoyard who dislikes the idea of Italian unity; Ernesto Masi's *Il Segreto del Re Carlo Alberto* (Bologna, 1891) is a very illuminating essay; Domenico Perrero, *Gli Ultimi Reali di Savoia* (Turin, 1869), L. Cappelletti, *Storia di Carlo Alberto* (1891); Nicomede Bianchi, *Storia della diplomazia europea in Italia* (8 vols., Turin, 1865, etc.), a most important work of a general character, and the same author's *Scritti e lettere di Carlo Alberto* (1879) and his *Storia della monarchia piemontese* (Turin, 1877); Count S. della Margherita, *Memorandum storico-politico* (Turin, 1851); A. Luzio, *Carlo Alberto e Giuseppe Mazzini* (1923); he also edited *Le Lettere di Carlo Alberto al Cav. Luigi Bianco di Barbania* (Turin, 1924); A. di Saluzzo, *Carlo Alberto della restaurazione all' avvenimento al trono* (1926).

CHARLES AUGUSTUS (Karl August) (1757–1828), grand-duke of Saxe-Weimar, friend and patron of Goethe, was the son of Constantine, duke of Saxe-Weimar-Eisenach, and Anna Amalia of Brunswick. Educated under the regency of his mother—his father died in 1757—Charles Augustus assumed the reins of government in 1775, in which year he married Princess Louise of Hesse-Darmstadt. In the affairs of Germany and of Europe his character gave him an influence out of all proportion to his position as a sovereign prince. He had early faced the problem presented by the decay of the empire, and began to work for the unity of Germany. The plans of the emperor Joseph II., which threatened to absorb a great part of Germany into the heterogeneous Habsburg monarchy, threw him into the arms of Prussia, and he was the prime mover in the establishment of the league of princes (*Fürstenbund*) in 1785, by which, under the leadership of Frederick the Great, Joseph's intrigues were frustrated. He was, however, under no illusion as to the power of Austria, and he wisely refused the offer of the Hungarian crown, made to him in 1787 by Prussia at the instance of the Magyar malcontents, with the dry remark that he had no desire to be another "Winter King." In 1788 he took service in the Prussian army as major-general in active command of a regiment. As such he was present, with Goethe, at the cannonade of Valmy in 1792, and in 1794 at the siege of Mainz and the battles of Pirmasenz (Sept. 14) and Kaiserslautern (Oct. 28–30). After this, dissatisfied with the attitude of the Powers, he resigned; but rejoined on the accession of his friend King Frederick William III. to the Prussian throne. The disastrous campaign of Jena (1806) followed; on Oct. 14, the day after the battle, Weimar was sacked; and Charles Augustus, to prevent the confiscation of his territories, was forced to join the Confederation of the Rhine. From this time till after the Moscow campaign of 1812 his contingent fought under the French flag in all Napoleon's wars. In 1813, however, he joined the Grand Alliance, and at the beginning of 1814 took the command of a corps of 30,000 men operating in the Netherlands.

At the Congress of Vienna Charles Augustus was present in person and protested vainly against the narrow policy of the Powers in confining their debates to the "rights of the princes" to the exclusion of the "rights of the people." His services in the war of liberation were rewarded with an extension of territory and the title of grand-duke. He was the first of the German princes to grant a liberal constitution to his state under Article XIII. of the Act of Confederation (May 5, 1816); and his concession of full liberty to the press made Weimar for a while the focus of journalistic agitation against the existing order. Metternich dubbed him contemptuously "der grosse Bursche" for his patronage of the "revolutionary" Burschenschaften; and the celebrated "festival" held at the Wartburg by his permission in 1818 brought down upon him the wrath of the Great Powers. Charles Augustus was compelled to yield to the remonstrances of Prussia, Austria and Russia; the liberty of the press was again restricted in the grand-duchy, but, thanks to the good understanding between the grand-duke and his people, the régime of the Carlsbad Decrees pressed less heavily upon Weimar than upon other German States.

Charles Augustus died on June 14, 1828, and left two sons; Charles Frederick (d. 1853), by whom he was succeeded, and Bernhard, duke of Saxe-Weimar (1792–1862), who distinguished himself as commander of the Dutch troops in the Belgian campaign of 1830, and from 1847 to 1850 held the command of the forces in the Dutch East Indies. Bernhard's son, William Augustus Edward, known as Prince Edward of Saxe-Weimar (1823–1902), entered the British army, served with much distinction in the Crimean War, and became colonel of the 1st Life Guards and a field-marshal; in 1851 he contracted a morganatic marriage with Lady Augusta Gordon-Lennox (d. 1904), daughter of the 5th duke of Richmond and Gordon, who in Germany received the title of countess of Dornburg, but was granted the rank of princess in Great Britain by royal decree in 1866.

Bibliography.—Karl August's Correspondence with Goethe was published in 2 vols. at Weimar in 1863. *See* F. X. Wegele, *Karl August, Grossherzog von Sachsen-Weimar* (Leipzig, 1850); W. Wachsmuth, *Herzog Karl August und Goethe* (Leipzig, 1911); W. Bode, *Karl August von Weimar, Jugendjahre* (1913); H. von Egloffstein, *Karl August während des Krieges von 1813* (1913) and *Karl August auf dem Wiener Kongress* (Jena, 1915).

CHARLES D'ORLÉANS: *see* Orléans, Charles, Duke of.

CHARLES EDWARD (Charles Edward Louis Philip Casimir Stuart) (1720–1788), English prince, called the "Young Pretender" and also the "Young Chevalier," was born at Rome on Dec. 31, 1720. He was the grandson of King James II. of England and elder son of James, the "Old Pretender," by whom (as James III.) he was created at his birth prince of Wales, the title he bore

among the English Jacobites during his father's lifetime. The young prince was educated at his father's miniature court in Rome, with James Murray, Jacobite earl of Dunbar, for his governor, and under various tutors, amongst whom were the learned Chevalier Ramsay, Sir Thomas Sheridan and the abbé Légoux. He learned the English, French and Italian languages, but his extant letters in English are singularly ill-spelt and illiterate. In 1734 he accompanied his cousin, the duke of Liria, afterwards duke of Berwick, on his expedition in aid of Don Carlos, and the boy of 13 shared with credit the dangers of the successful siege of Gaeta.

The Old Pretender calculated upon foreign aid in his attempts to restore the monarchy of the Stuarts; and the idea of rebellion unassisted by invasion or by support of any kind from abroad, was Charles Edward's own. Jacobite hopes mainly rested in France, and the warm sympathy which Cardinal Tencin, who had succeeded Fleury as French minister, felt for the Old Pretender resulted in a definite scheme for an invasion of England to be timed simultaneously with a prearranged Scottish rebellion. Charles was secretly despatched to Paris in January, 1744. A squadron under Admiral Roquefeuil sailed (Feb. 6) from Brest. Transports for 7,000 troops, to be led by Marshal Saxe, accompanied by the young prince, were in readiness to set sail for England. Meanwhile a strong English fleet appeared in the Downs, and a series of storms provided a probably welcome excuse to the French government for the cancellation of Marshal Saxe's orders. Louis declined to surrender Charles, but no official hospitality was offered him, and he lived in retirement. Charles Edward had made at Rome the acquaintance of Lord Elcho and of John Murray of Broughton; Murray visited him in Paris, and was told that he would come to Scotland in the summer of 1745, even though he came alone. His friends in Scotland saw no chance of success, and messengers, who do not seem to have reached him, were sent expressly to inform him. On July 13, 1745, he sailed from Nantes for Scotland on board the small brig "La Doutelle," which was accompanied by a war frigate, the "Elisabeth," provided by an Irishman at Dunkirk and laden with arms and ammunition. The latter fell in (July 20) with an English man-of-war, the "Lion," and had to return to France; Charles escaped during the engagement, and arrived on Aug. 3 off Erisca, a little island of the Hebrides. Receiving, however, but a cool reception from Macdonald of Boisdale, he set sail again and arrived at the Bay of Loch-na-nuagh on the west coast of Inverness-shire.

The Macdonalds of Clanranald and Kinloch Moidart, along with other chieftains, attempted in vain to dissuade him from the rashness of an unaided rising, but Lochiel and other chieftains, although they had sought to dissuade Charles from coming at all, now called out the clans. On Aug. 19, in the valley of Glenfinnan, the standard of James III. and VIII. was raised. Within a week about 2,000 men, mainly from the Macdonald clan, had joined him. Sir John Cope left Stirling for Inverness on Aug. 20 with 25 companies of foot, leaving the road to the south open to Charles. In the beginning of September the Jacobite army, reinforced by some accessions, notably by Lord George Murray, entered Perth. Crossing the Forth unopposed at the Fords of Frew and passing through Stirling and Linlithgow, he arrived within a few miles of Edinburgh, and on Sept. 16 a body of his skirmishers defeated the dragoons of Colonel Gardiner in what was known as the "Canter of Coltbrig." A few of Cameron's Highlanders having on the following morning, by a happy ruse, forced their way through the Canongate, Charles entered the city at noon. On the 18th he publicly proclaimed James VIII. of Scotland at the Market Cross and occupied Holyrood.

Cope had by this time brought his disappointed forces by sea to Dunbar. On the 20th Charles met and defeated him at Prestonpans, and returned to prosecute the siege of Edinburgh Castle, which, however, he raised on Gen. Guest's threatening to lay the city in ruins. He still hoped for French assistance definitely promised on Oct. 24 by secret treaty. In the beginning of November Charles left Edinburgh to invade England. He was at the head of at least 5,000 men; but the ranks were gradually thinned by the desertion of Highlanders, whose tradition had led them to consider war merely as a raid. Having passed through Kelso, on Nov. 9 he laid siege to Carlisle which capitulated in a week. Manchester provided the prince with 150 recruits under Francis Towneley. On Dec. 4 he had reached Derby. Charles's officers were under no illusions about the strength of English resistance, but hoped that the advance might lead to intervention from France. When they found that the English counties did not rise they advised retreat. Two armies under English leadership were now in the field against Charles, one under Marshal Wade, whom he had evaded by entering England by the west, and the other under William, duke of Cumberland, who had returned from the Continent. On Dec. 6 Charles began his retreat northward. Closely pursued by Cumberland, he marched by way of Carlisle across the border, and at last stopped to invest Stirling Castle. At Falkirk, on Jan. 17, 1746, he defeated Gen. Hawley, who had marched from Edinburgh to intercept his retreat. The Jacobite army had been strengthened by Gordons, Mackintoshes and others, but the accessions were counter-balanced by desertions. A fortnight later, however, Charles raised the siege of Stirling, and after a weary march rested his troops at Inverness. Having taken Forts George and Augustus, and after varying success against the supporters of the government in the north, he at last prepared to face the duke of Cumberland, who had passed the early spring at Aberdeen. On April 8 the duke marched thence to meet Charles, whose little army, exhausted with a futile night march, half-starving, and broken by desertion, was completely worsted at Culloden on April 16, 1746.

This decisive defeat sealed the fate of Charles Edward and the house of Stuart. Hunted hither and thither Charles, upon whose head a reward of £30,000 had a year before been set, was for over five months relentlessly pursued by the troops and spies of the government. Disguised in female attire and aided by a passport obtained by the devoted Flora MacDonald, he passed through Skye, and towards the end of July took refuge in the cave of Coiraghoth in the Braes of Glenmoriston. In August he joined Lochiel and Cluny Macpherson, with whom he remained in hiding until the arrival of two French ships at Loch-na-nuagh, enabled him to sail for France. He reached Roscoff, near Morlaix, on Sept. 29, 1746. He remained in France for two years, but the Treaty of Aix-la-Chapelle entailed his expulsion from France. After his brother Henry's acceptance of a cardinal's hat in July 1747, he broke off communication with his father in Rome (who had approved the step), nor did he ever see him again. The enmity of the British government to Charles Edward made peace with France an impossibility so long as she continued to harbour the young prince. A condition of the Treaty of Aix-la-Chapelle, concluded in October 1748, was that every member of the house of Stuart should be expelled from the French dominions. Charles declared, he would not be bound by its provisions. But his indignation and persistent refusal to leave France were met at last with force; he was apprehended, imprisoned for a week at Vincennes, and on Dec. 17 conducted to the French border. He lingered at Avignon; but Pope Benedict XIV., alarmed by the threat of a bombardment of Civita Vecchia, advised the prince to withdraw. Charles quietly disappeared. For years Europe watched for him in vain. It is now established, almost with certainty, that he returned to the neighbourhood of Paris. In 1750 and again, it is thought, in 1754, he was in London, hatching futile plots and risking his safety for his hopeless cause, and even abjuring the Roman Catholic faith in order to further his political interests.

During the next ten years of his life Charles Edward's illicit connection with Miss Clementina Walkinshaw (d. 1802), whom he had first met at Bannockburn House while conducting the siege of Stirling, his imperious fretful temper, his drunken habits and debauched life, could no longer be concealed. He wandered over Europe in disguise, alienating his friends and crushing the hopes of his party; and in 1766, on returning to Rome at the death of his father, he was treated by Pope Clement XIII. with coldness, and his title as heir to the British throne was openly repudiated by all the great Catholic powers. It was probably through the influence of the French court, still intriguing against England, that the marriage between Charles (now self-styled count of Albany) and Princess Louise of Stolberg was arranged in 1772. The union proved childless and unhappy, and in 1780 the countess fled for

refuge from her husband's drunken violence to a convent in Florence. Later, the countess of Albany (*q.v.*) threw herself on the protection of her brother-in-law Henry, Cardinal York, at Rome, and a formal separation was arranged in 1784. Charles, lonely, ill, and evidently near death, now summoned to Florence his natural daughter, Charlotte Stuart, the child of Clementina Walkinshaw, born at Liége in October 1753 and hitherto neglected by the prince. Charlotte Stuart, who was declared legitimate and created duchess of Albany, tended her father for the remaining years of his life. She contrived to reconcile the two Stuart brothers, so that in 1785 Charles returned to Rome, where he died in the old Palazzo Muti on Jan. 30, 1788. He was buried in his brother's cathedral church at Frascati, but in 1807 his remains were removed to the *Grotte Vaticane* of St. Peter's. His daughter Charlotte died unmarried at Bologna in November, 1789.

CHARLES EMMANUEL I. (CARLO EMANUELE) (1562–1630), duke of Savoy, succeeded his father, Emmanuel Philibert, in 1580. His three chief objects were the conquest of Geneva, of Saluzzo and of Monferrato. Saluzzo he succeeded in wresting from France in 1588. In 1590 he sent an expedition to Provence in the interests of the Catholic League, and followed it himself later, but the peace of 1593, by which Henry of Navarre was recognized as king of France, put an end to his ambitions. In the war between France and Spain Charles sided with the latter, with varying success. Finally, by the Peace of Lyons (1601), he gave up all territories beyond the Rhône, but his possession of Saluzzo was confirmed. His attempt to capture Geneva by treachery and with the help of Spain (the famous *escalade*) in 1602 failed completely. On the death in 1612 of Duke Francesco Gonzaga of Mantua, who was lord of Monferrato, Charles Emmanuel made a successful *coup de main* on that district. This arrayed the Venetians, Tuscany, the Empire and Spain against him, and he was obliged to relinquish his conquest. The terms of the peace of 1618 left him more or less in the *status quo ante*. In 1628 he was in alliance with Spain in the war against France and the French invaded the duchy. The duke fought desperately, but was taken ill at Savigliano and died in 1630. He was succeeded by his son Victor Amedeo I., while his third son Tommaso founded the line of Savoy-Carignano from which the present royal house of Italy is descended.

See E. Ricotti, *Storia della monarchia piemontese*, vols. iii. and iv. (Florence, 1865); T. Raulich, *Storia di Carlo Emanuele I.* (Milan, 1896–1902); G. Curti, *Carlo Emanuele I. secondo; più recenti studii* (Milan, 1894).

CHARLES MARTEL, "The Hammer," (*c.* 688–741), Frankish ruler, son of Pippin II., mayor of the palace, and Chalpaïda. Charles was baptized by St. Rigobert, bishop of Reims. At the death of his father in 714, Pippin's widow Plectrude claimed the government in Austrasia and Neustria in the name of her grandchildren, and had Charles thrown into prison. But the Neustrians threw off the Austrasian yoke and entered into an offensive alliance with the Frisians and Saxons. In the general anarchy Charles succeeded in escaping, defeated the Neustrians at Amblève, south of Liége, in 716, and at Vincy, near Cambrai, in 717, and forced them to come to terms. In Austrasia he wrested the power from Plectrude, and took the title of mayor of the palace, thus prejudicing the interests of his nephews. According to the Frankish custom he proclaimed a king in Austrasia in the person of the young Clotaire IV., but in reality Charles was the sole master—the entry in the annals for the year 717 being "Carolus regnare coepit." Once in possession of Austrasia, Charles sought to extend his dominion over Neustria also. In 719 he defeated Ragenfrid, the Neustrian mayor of the palace, at Soissons, and forced him to retreat to Angers. Ragenfrid died in 731, and from that time Charles had no competitor in the western kingdom. He obliged the inhabitants of Burgundy to submit, and disposed of the Burgundian bishoprics and countships to his *leudes*. In Aquitaine Duke Odo (Eudes) exercised independent authority, but in 719 Charles forced him to recognize the suzerainty of northern France, at least nominally. After the alliance between Charles and Odo on the field of Poitiers, the mayor of the palace left Aquitaine to Odo's son Hunald, who paid homage to him. Besides establishing a certain unity in Gaul, Charles saved it from a very great peril. In 711 the Arabs had conquered Spain. In 720 they crossed the Pyrenees, seized Narbonensis, a dependency of the kingdom of the Visigoths, and advanced on Gaul. By his able policy Odo succeeded in arresting their progress for some years; but a new vali, 'Abd-ar-Rahmān, a member of an extremely fanatical sect, resumed the attack, reached Poitiers, and advanced on Tours, the holy town of Gaul. In Oct. 732 (just 100 years after the death of Mohammed) Charles gained a brilliant victory over 'Abd-ar-Rahmān, who was called back to Africa by the revolts of the Berbers and had to give up the struggle. This was the last of the great Arab invasions of Europe. After his victory Charles took the offensive, and endeavoured to wrest Narbonensis from the Muslims. Although he was not successful in his attempt to recover Narbonne (737), he destroyed the fortresses of Agde, Béziers and Maguelonne, and set fire to the amphitheatre at Nîmes. He subdued also the Germanic tribes; annexed Frisia, where Christianity was beginning to make progress; put an end to the duchy of Alemannia; intervened in the internal affairs of the dukes of Bavaria; made expeditions into Saxony; and in 738 compelled some of the Saxon tribes to pay him tribute. He also gave St. Boniface a safe conduct for his missions in Thuringia, Alemannia and Bavaria.

During the government of Charles Martel important changes appear to have been made in the internal administration. Under him began the great assemblies of nobles known as the *champs de Mars*. To attach his *leudes* Charles had to give them church lands as *precarium*, and this had a very great influence in the development of the feudal system. It was from the *precarium*, or ecclesiastical benefice, that the feudal fief originated. Vassalage, too, acquired a greater consistency at this period, and its rules began to crystallize. Under Charles occurred the first attempt at reconciliation between the papacy and the Franks. Pope Gregory III., menaced by the Lombards, invoked the aid of Charles (739), sent him a deputation with the keys of the Holy Sepulchre and the chains of St. Peter, and offered to break with the emperor and Constantinople, and to give Charles the Roman consulate (*ut a partibus imperatoris recederet et Romanum consulatum Carolo sanciret*). This proposal, though unsuccessful, was the starting point of a new papal policy. Since the death of Theuderich IV. in 737 there had been no king of the Franks. In 741 Charles divided the kingdom between his two sons, as though he were himself master of the realm. To the elder, Carloman, he gave Austrasia, Alemannia and Thuringia, with suzerainty over Bavaria; the younger, Pippin, received Neustria, Burgundy and Provence. Shortly after this division of the kingdom Charles died at Quierzy on Oct. 22, 741, and was buried at St. Denis. The characters of Charles Martel and his grandson Charlemagne offer many striking points of resemblance. Both were men of courage and activity, and the two men are often confused in the *chansons de geste*.

CHARLES CITY, a city of northern Iowa, U.S.A., on Cedar river; the county seat of Floyd county. It is on federal highways 18 and 218 and served by the Chicago, Milwaukee, St. Paul and Pacific, Illinois Central, and Charles City Western railways. The population in 1930 federal census was 8,039; in 1940, 8,681; in 1950, 10,277.

It is in a rich agricultural region; has abundant water power; manufactures tractors, office equipment and other articles; and has extensive nurseries, specializing in evergreens and roses.

The city was founded in 1850 and incorporated in 1860.

CHARLESTON, a city of eastern Illinois, U.S., on the Nickel Plate and the Big Four railways, 45 mi. W. of Terre Haute, Ind.; the county seat of Coles county. Pop. (1950) 9,146; (1940) 8,197. It has broom and shoe factories and railroad shops. The Eastern Illinois State Teachers college, established in 1895, has an enrolment of about 1,500. In the vicinity are the Lincoln Log Cabin State park and the Fox Ridge State park. Charleston was made the county seat in 1831 and was incorporated in 1839. One of the Lincoln-Douglas debates was held there in 1858.

CHARLESTON, oldest city of South Carolina, U.S., is an important South Atlantic seaport, an industrial area and an all-year resort, on a narrow peninsula between the Cooper and Ashley rivers, at the head of the bay (Charleston harbour) formed by their confluence, 7½ mi. from the ocean bar. It is the county seat of Charleston county, headquarters of the customs district of South Carolina, headquarters of the 6th naval district, official state port and headquarters of the South Carolina Ports authority. Charleston is on federal highways 17, 701, 52, 176 and 78; and is served by the Atlantic Coast Line, the Seaboard Air Line and the Southern railways, by Eastern, National, Delta and Southern air lines; also by a number of coastwise, intercoastal and foreign steamship lines.

The population in the 1950 federal census was 68,243 and that of Charleston county, constituting the Charleston metropolitan area, was 159,838. The city, whose city limits had not been extended in more than 100 years, has a total land area of only 5.12 sq.mi., of which 4.5 is usable; the highest elevation above datum plane is 16 ft.; the waterfront area within the city limits extends for nine miles.

On islands in the harbour are Fort Sumter and Castle Pinckney, both national monuments. At the southwest corner of the city, on the Ashley river, are the Atlantic fleet naval minecraft base headquarters. North of the city, on the west bank of the Cooper river, is the Charleston naval base and naval shipyard, with lengthy docks, ship repair facilities and destroyer building ways. Still farther north (10.4 mi. above the custom house) are the vast port terminals. Also in this vicinity is a U.S. ordnance depot.

The spacious harbour, almost landlocked, protected by two converging stone jetties (15,443 and 19,104 ft. long), accommodates vessels with a draught of 30 ft. Inbound traffic consists principally of petroleum products, Egyptian long-staple cotton, materials for fertilizer manufacture and sugar; outbound traffic, of cotton and cotton goods from the Carolinas and Georgia, coal from West Virginia and Virginia, crossties, treated and untreated lumber, petroleum products and peanuts. Trade with foreign countries in 1950 amounted to 953,047 tons. Customs revenues at the end of the fiscal year July 2, 1950, totalled $2,522,039. Charleston is an important centre for the distribution of oil and has several large fertilizer plants. Following World War II its industrial development and growth were substantial, with more than 50 new industries having been established by 1951, the majority at the northern end of the peninsula well outside the city limits. Among the leading manufactures are wood pulp and allied products, woven asbestos, pressure creosoted timber, cigars, men's shirts, optical products, furniture, steel products and ironwork. The city is a bunkering and repair station for both commercial and naval vessels; a market for the agricultural products (notably vegetables cotton and tobacco) and the pine and hardwoods of the state, and for the fresh and canned oysters, crabs, shrimp and fish caught off the coast.

Charleston has a unique charm and beauty. At the lower end of the peninsula is the Battery, or White Point gardens, planted with live oaks and palmettos. Beach resorts (Isle of Palms, Sullivan's Island and Folly beach) are developed on outlying islands which formerly (until 1718) were the haunts of pirates.

The Magnolia gardens, up the Ashley river, are a monument to the exquisite taste and poetic imagination of the Rev. John Grimké Drayton, who created them when in the 1840s his physician ordered him to lead an outdoor life. At Middleton Place, farther up the river, one wing of the great Tudor mansion still stands, and there are gardens which had renown in England in the 18th century. Other noted garden estates are Cypress Gardens, Runnymede, Pierates Cruze and Mateeba. Among the many educational institutions of the city are the College of Charleston, founded in 1770, chartered in 1785 and taken over by the city in 1837 (the first municipal college in the country); the Medical College of the State of South Carolina, a state institution founded in 1823; and the Citadel, The Military College of South Carolina, created by the legislature in 1842. The Charleston library was founded in 1748; the museum in 1773.

The first English settlement in South Carolina, named after the reigning king, was made at Albemarle point on the west bank of the Ashley in 1670; but in 1672 a new town was begun on the present site, and the seat of government was moved to it in 1680. It soon became the largest and wealthiest settlement south of Philadelphia, Pa.; the brilliant social and cultural centre of the province and later of the state; the home of the Pinckneys, the Rutledges, the Gadsdens, the Laurenses and many other notable families. Magnificent estates were developed in the surrounding country. The port shipped one specialty after another—rice, indigo, tobacco, lumber, cotton—before entering on its present phase as a more general cargo port. Charleston was the capital of the state until 1790. Until 1783 it was governed by ordinances passed by the legislature and enforced partly by provincial officials and partly by the churchwardens. The city charter of 1783, with many amendments, is still in force.

Charleston was attacked by a combined fleet of Spanish and French in 1706; withstood attacks from the British in 1776 and in 1779, but in 1780 was captured from the land side by Sir Henry Clinton and became the base of operations in the Carolinas, remaining under military rule until Dec. 14, 1782. It was the centre of the nullification movement of 1832–33. The bombardment and capture of Ft. Sumter (April 12–13, 1861) by the South Carolinians marked the beginning of the Civil War. From 1862 to 1865 Charleston was almost continually under siege by the Federal naval and military forces, and on Feb. 17, 1865, the Confederates evacuated the city, after burning large stores of cotton and other supplies to keep them from coming into possession of the enemy. Charleston was devastated by hurricanes in 1699, in 1752 and in 1854; by epidemic in 1699 and in 1854; by fire in 1740; and by an earthquake on Aug. 31, 1886, which damaged 90% of the buildings.

Courtenay, *Charleston, S.C.* (1884); Albert Simons and Samuel Lapham, Jr., *Charleston, South Carolina,* including sketches of many of the historic buildings (1927); Robert Molloy, *Charleston, a Gracious Heritage* (1947); William Oliver Stevens, *Charleston, Historic City of Gardens* (1939); S. G. Stoney, *Charleston, Azaleas and Old Bricks* (1939).

CHARLESTON, the capital of West Virginia, U.S., on the Kanawha river at the mouth of the Elk, southwest of the centre of the state; the county seat of Kanawha county. It is on U.S. highways 21, 35, 60, 119; and is served by the Baltimore and Ohio, Chesapeake and Ohio, New York Central and Virginian railways and by American, Eastern, Capital and Piedmont air lines. There is inland waterway transportation to the Gulf of Mexico. The population in 1950 was 73,501; in 1940 it was

area for the production of natural resources (coal, oil, natural gas, salt brines, limestone, lumber, clays) and manufacture of base chemicals (nylon basic salt, Vinylite and polyethylene resins, antifreezes), glass, farm implements, brick and tile and synthetic rubber. There is a U.S. naval ordnance plant for production of armour plate, naval guns and projectiles. Manufacturing and natural-resource-production investments were estimated in excess of $600,000,000 in 1950. Charleston's assessed valuation of property in 1950 was $161,784,100. An outstanding capitol was completed there in 1933 to replace the one built in 1880.

Charleston was settled soon after the American Revolution and was incorporated in 1794. It was on the route of migration to the Ohio valley and became a transfer and shipping centre. Daniel Boone and Simon Kenton, noted frontiersmen, operated in the Charleston area and Boone represented Charleston in the Virginia assembly, 1790–91. In 1870, when Charleston was chartered as a city, the population was only 3,162. Charleston remained the

capital of the state from 1870 excepting for the decade 1875–85, when the capital was Wheeling.

CHARLESTOWN, formerly a separate city of Middlesex county, Mass., U.S., but since 1874 a part of the city of Boston, with which it had long before been in many respects practically one. It is situated on a small peninsula on Boston harbour, between the mouths of the Mystic and Charles rivers; the first bridge across the Charles, built in 1786, connected Charlestown and Boston. A large and important United States navy yard (1800), and the Massachusetts state prison (1805) are there; the old burying ground contains the grave of John Harvard and that of Thomas Beecher, the first American member of the famous Beecher family; and there is a soldiers' and sailors' monument (1879), designed by Martin Milmore. Charlestown was founded in 1628 or 1629, being the oldest part of Boston, and soon rose into importance; it was organized as a township in 1630, and was chartered as a city in 1847. Within its limits was fought, on June 17, 1775, the battle of Bunker Hill (*q.v.*), when Charlestown was almost completely destroyed by the British. The Bunker Hill monument commemorates the battle. The original territory of the township was very large, and from parts of it were formed Woburn (1642), Malden (1649), Stoneham (1725) and Somerville (1842); other parts were annexed to Cambridge, to Medford and to Arlington. S. F. B. Morse, the inventor of the electric telegraph, was born there; and Charlestown was the home of Samuel Dexter (1761–1816), an eminent lawyer, secretary of war in the cabinet of Pres. John Adams, and of Oliver Holden (1765–1837), a composer of hymn tunes, including "Coronation."

BIBLIOGRAPHY.—R. Frothingham, *History of Charlestown* (1845), covering 1629–1775; J. F. Hunnewell, *A Century of Town Life . . . 1775–1887* (1888); Timothy T. Sawyer, *Old Charlestown* (1902); and H. H. Sprague, *The Founding of Charlestown by the Spragues* (1910).

CHARLET, NICOLAS TOUSSAINT (1792–1845), French designer and painter, more especially of military subjects, was born in Paris on Dec. 20, 1792, and died there on Oct. 30, 1845. The son of a dragoon in the Republican army, he was educated at the Lycée Napoléon, and served in the national guard in 1814. In 1816 Charlet entered the atelier of Antoine Gros, and soon began issuing the first of those lithographed designs of subjects drawn from the Napoleonic wars which eventually brought him renown. Lithographs (about 2,000 altogether), water colours, sepia drawings, numerous oil sketches and a few etchings followed one another rapidly, and he exhibited some large canvases. His best work was the "Episode in the Retreat from Russia," exhibited in the salon of 1836.

See De La Combe, *Charlet, sa vie, ses oeuvres* (1856).

CHARLEVILLE, a town of northeastern France, in the department of Ardennes, 50 mi. N.E. of Reims. Pop. (1946) 19,163. Charleville is situated within a bend of the Meuse on its left bank, opposite Mézières, with which it is united by a suspension bridge. The town was founded in 1606 by Charles III (Gonzaga), duke of Nevers, afterward duke of Mantua, and is laid out on a definite plan. The Place Ducale is a large square surrounded by old houses. On the right bank of the Meuse is Mont Olympe, with the ruins of a fortress dismantled under Louis XIV. Charleville, which shares with Mézières the administrative institutions of the department of Ardennes, has tribunals of first instance and of commerce, a chamber of commerce and a board of trade-arbitrators. Its chief industries are metal founding, the manufacture of iron goods and the making of bricks. Brushes and clay pipes are also made.

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE (1682–1761), French Jesuit traveller and historian, was born at St. Quentin, Fr., on Oct. 29, 1682. At 16 he entered the Society of Jesus; and at 23 was sent to Canada, where he remained for four years as professor at Quebec, Que. In 1720–22, under orders from the regent, he visited North America for the second time, and went along the Great Lakes and down the Mississippi. He died at La Flèche, Fr., on Feb. 1, 1761.

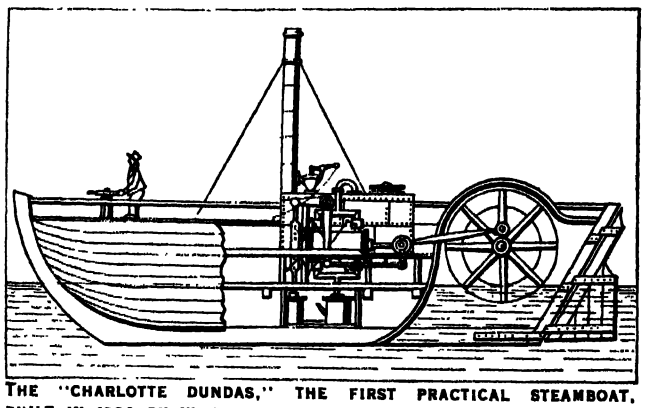
Among his works are: ***Histoire de l'isle espagnole ou de Saint Domingue*** (1730), based on manuscript memoirs of P. Jean-Baptiste le Pers and original sources; ***Histoire de Paraguay*** (1756); ***Vie de la Mère Marie de l'incarnation, institutrice et première supérieure des Urselines de la Nouvelle France*** (1724); ***Histoire et description générale de la Nouvelle France*** (1744; in English 1761; tr. J. G. Shea, 1866–72), a work of capital importance for Canadian history.

CHARLEVOIX, a city of Michigan, U.S., on Lake Michigan, with Lake Charlevoix on its eastern boundary and Round lake harbour in the centre of the town; a port of entry and the county seat of Charlevoix county. It is on federal highway 31 and state highway 66, and is served by the Chesapeake and Ohio railway, buses and lake steamers.

The population in 1950 was 2,664. The summer population is more than 10,000. Charlevoix is one of the most popular summer resorts of the state, and has a considerable fishing industry. It was platted as a village in 1866, and was incorporated as a city in 1905.

CHARLOTTE (1840–1927), empress of Mexico, only daughter of Leopold I, king of Belgium, and Louise, princess of Orleans, was born at Laeken, near Brussels, on June 7, 1840. She married in 1857 the archduke Maximilian of Austria, and went with him to Mexico in 1864, when he accepted the Mexican crown. When it became evident in 1866 that Maximilian's position was untenable, she was sent by her husband to Europe to implore the assistance of Napoleon III, who had decided to withdraw the French troops from Mexico. In this mission she failed, and foreseeing a catastrophe (Maximilian was shot in 1867) she went out of her mind (Sept. 1866). Charlotte was placed by her family under care in a Belgian château and survived until Jan. 19, 1927. (*See* also MAXIMILIAN.)

See Count Corti, ***Maximilian und Carlotta von Mexico,*** 2 vol. (1924).



CHARLOTTE, a city of Michigan, U.S., 18 mi. S.W. of Lansing; on federal highway 27, and served by the Grand Trunk and the Michigan Central railways; the county seat of Eaton county. The population in 1950 was 6,589; in 1940 it was 5,544. It has varied manufacturing industries, including radio and television, and is the trade centre of a rich agricultural and dairying region, which raises large quantities of beans.

CHARLOTTE, a city in southern North Carolina, U.S., 175 mi. S.W. of Raleigh; the county seat of Mecklenburg county. It is on federal highways 21, 29 and 74; and is served by the Southern, the Norfolk and Southern, the Piedmont and Northern Electric and the Seaboard Air Line railways; also by Capital and Eastern air lines. The population in 1950 was 133,219, and in 1940 it was 100,899 by the federal census. Cotton, corn, wheat and truck crops are grown in the vicinity. Charlotte is at the heart of the hydroelectric development and the textile industry of the southern Piedmont. Many northern manufacturers of machinery, dyestuffs and other items needed for the equipment of cotton mills have branches there, and it is a distributing point for automobiles and their accessories. Bank clearings for 1949 amounted to $3,981,298,386. The assessed valuation of property in 1949, was $200,000,000. Within the city limits are large textile mills and knitting mills. The output of the Charlotte factories includes approximately 200 diversified products. Printing and publishing is an important industry.

Charlotte is the seat of Queens college for women, originally chartered by the colonial legislature in 1771; and of the Johnson C. Smith university for Negroes (formerly Biddle university), founded in 1867. The city was settled about 1750, and incorporated in 1768. It has a commission form of government with mayor, city manager and seven councilmen. A monument in front of the courthouse commemorates the signing of the Mecklenburg Declaration of Independence in May 1775. For a brief period in 1780 the city was occupied by Lord Cornwallis, who nicknamed it "the hornets' nest." Later it became the principal base of Gen. Nathanael Greene's operations. Andrew Jackson and James K. Polk were born near by, and on April 10, 1865, Jefferson Davis convened his cabinet there for its last meeting.

"CHARLOTTE DUNDAS," the name given by her inventor to the first practical steamship. William Symington, in 1802, built the tug "Charlotte Dundas," a paddle-wheel steamer, and successfully tried her on the Forth and Clyde canal; the name

was a compliment to the family of Lord Dundas, who suggested the experiment, and the boat was built for the Forth and Clyde Canal Company. The motive-power employed was a double-acting condensing engine constructed by James Watt. The engine was fixed horizontally and actuated the crank of a stern-shaft which carried the paddle-wheel. The "Charlotte Dundas" managed to tow two vessels with a burden of 140 tons, in the teeth of a strong

THE "CHARLOTTE DUNDAS," THE FIRST PRACTICAL STEAMBOAT, BUILT IN 1802 BY WILLIAM SYMINGTON AND DRIVEN BY AN ENGINE SUPPLIED BY JAMES WATT

wind, at the rate of 3¼m. an hour. Five years later, the American Robert Fulton, who had witnessed the "Charlotte Dundas" experiment, built the famous "Clermont" on the River Hudson.

CHARLOTTENBURG, a town incorporated in the Greater Berlin scheme of 1912 (which came into full operation in 1920), in the *Land* of Prussia, on the river Spree; its earlier name was Lietzenburg. The central part of the town is connected with Berlin by an avenue, the Charlottenburger Chaussée. The Schloss, built in 1696 for the electress Sophie Charlotte, queen of the elector Frederick, after whom the town was named, contains a collection of antiquities and paintings. In Charlottenburg is the Physikalisch-technische Reichsanstalt, a state institution for the carrying out of scientific experiments and measurements, and for testing instruments of precision, materials, etc. In addition to the famous royal porcelain manufactory, there are many industries, notably iron-works, grouped along the banks of the Spree.

CHARLOTTESVILLE, a city in the beautiful Piedmont region of Virginia, U.S., on the Rivanna river, 70 mi. W.N.W. of Richmond; the county seat of Albemarle county, but administratively independent of it. It is served by the Chesapeake and Ohio and the Southern railways. The population in 1950 was 25,969, and in 1940, 19,400, by federal census. It is the seat of the University of Virginia and the trade centre of an agricultural district noted for its fine apples and peaches. There are a law-book publishing house, woollen mill, silk mill, dress shirt and underwear plants and pen and pencil factory.

On a hill three miles east, visible from all parts of the city, is Monticello, the home of Thomas Jefferson from 1770 until his death, now a national memorial. The house was planned by Jefferson and built under his supervision. It is one of the most interesting examples of colonial architecture. His grave is on the estate. Two miles beyond Monticello is Ash Lawn, home of James Monroe. Mirador, the girlhood home of Lady Astor, is about 20 mi. west of the city. The site of Charlottesville was a part of the Castle Hill estate of Thomas Walker (1715–94). The town (named after Queen Charlotte) was incorporated in 1762. In 1888 it was chartered as a city, independent of the county. It has a commission manager form of government. In 1779–80 about 4,000 of Gen. John Burgoyne's troops, surrendered under the convention of Saratoga, were quartered there. In June 1781 Sir Banastre Tarleton raided the town and vicinity, destroying the public records and nearly capturing Jefferson. Jefferson owed his escape to the warning brought by a young Virginian soldier, Jack Jouett, who rode 40 mi. across rough country through the night to outstrip Tarleton, after accidently getting a clue to his plans through conversation overheard at a tavern.

CHARLOTTETOWN, the capital of the province of Prince Edward Island, Can., situated in Queen's county, on Hillsborough river. Pop. (1951) 15,887. It has a good harbour, and the river is navigable by large vessels for several miles. The export trade of the island centres there, and the city has regular communication by steamer with the chief U.S. and Canadian ports, is served by the Canadian National railways through a ferry service and has a large terminal airport.

Besides the government buildings and the courthouse, it contains the Prince of Wales college, supported by the province, the Roman Catholic college of St. Dunstan's and a normal school. Among its manufactures are woollen goods, lumber, canned goods and foundry products; its fisheries are extensive and important. The town was founded in 1750 by the French under the name of Port la Joie, but under British rule it changed its name in honour of the queen of George III.

CHARM, an incantation, verses sung with supposed magical results, hence anything possessing powers of bringing good luck or averting evil, particularly articles worn with that purpose, such as an amulet. It is thus used of small trinkets attached to bracelets or chains. The word is also used, figuratively, of fascinating qualities of feature, voice or character. It is derived through the Fr. from the Lat. *carmen,* a song.

CHARMES, FRANCIS (1848–1916), French journalist and politician, was born at Aurillac, Cantal, on April 21, 1848. He was educated at Aurillac and at the lycées of Clermont-Ferrand and Poitiers. He was editor of the *Journal des Débats* from 1872 to 1880, and from 1889 to 1907. During the interval he served in the political department of the Foreign office. He sat in the chamber of deputies from 1881 to 1885 and from 1889 to 1898, and in 1900 became a senator. Charmes is, however, best known for his connection with the *Revue des Deux Mondes.* In 1893 he began his famous political writings in the *Revue,* and in 1907 became its editor. His literary and political articles were one of the features of French literary history during the last years of the 19th century. He died in Paris on Jan. 4, 1916.

CHARMEUSE. In textiles, the proprietary name for a silk dress fabric of light and delicate texture suitable for gowns, party wraps, and such like garments for purely dress purposes, and for which strength and durability are not essential qualities. This fabric has a rich and more lustrous appearance on the face side than on the reverse side, which latter is of a more subdued lustre. This difference in lustre results from the particular weave structure of the fabric, and the difference between the character, counts and number of warp and weft threads employed. A typical example of charmeuse consists of a very light texture developed by the 12-end warp-face satin weave, and produced from a grenadine organzine warp, and a two-ply pure schappe silk weft, or else crêpe de Chine twist for the warp, and schappe silk for the weft. Charmeuse is also sometimes developed by employing the warp-face satin weave in combination with a light voile foundation texture. This is produced by introducing two picks of fine and hard-twisted weft alternately with two picks of schappe silk weft. In this structure the fine picks of weft interweave with the warp threads in the plain weave order, that is, under and over successive warp threads, thereby serving to reinforce the satin weave texture which would otherwise be very weak and flimsy. After weaving, the fabric is piece-dyed and finished with the characteristic soft finish to which it owes its good draping qualities. (H. N.)

CHARNAY (CLAUDE JOSEPH), DÉSIRÉ (1828–1915), French traveller and archaeologist, was born in Fleurie (Rhône), studied at the Lycée Charlemagne, and in 1850 became a teacher in New Orleans, Louisiana. He travelled in Mexico under a commission from the French ministry of education, in 1857–61; in Madagascar in 1863; in South America, particularly Chile and Argentina, in 1875; and in Java and Australia in 1878. In 1880–83 he again visited the ruined cities of Mexico. Pierre Lorillard of New York contributed to defray the expense of this expedition, and Charnay named a great ruined city near the Guatemalan boundary line Ville Lorillard in his honour. Charnay went to Yucatan in 1886. His works include: *Le Mexique, souvenirs et impressions de voyage* (1863) and *Les Anciennes Villes*

du Nouveau Monde (1885; Eng. trans. 1887). He elaborated a theory of Toltec migrations and considered the prehistoric Mexican to be of Asiatic origin, because of observed similarities to Japanese architecture, Chinese decoration, Malaysian language and Cambodian dress, etc.

See *Recueil de Voyages*, etc., vol. xix (1903).

CHARNEL HOUSE, a place for the storage of human bones, specifically that rendered necessary by the fact that many crowded mediaeval cemeteries were used again and again, so that each new burial unearthed the bones of people long dead. Charnel houses were sometimes situated in church crypts, and sometimes as separate buildings in the churchyards; chantry chapels were occasionally added.

CHARNOCK, JOB (d. 1693), English founder of Calcutta, went to India in 1655 or 1656 and soon joined the East India company's service. He was stationed at Cossimbazar and then at Patna. In 1686 he became chief agent at Hugli. Besieged there by the Mogul viceroy of Bengal, he put the company's goods and servants on board his light vessels and dropped down the river 27 mi. to the village of Sutanati, a place well chosen for the purpose of defense, which occupied the site of what is now Calcutta. It was only, however, at the third attempt that Charnock finally settled down at this spot, and the selection of Calcutta as the capital of India was entirely due to his stubborn resolution.

See N. N. Raye, *The Annals of the Early English Settlement in Bihar* (Calcutta, 1927).

CHARNOCK or CHERNOCK, **ROBERT** (*c.* 1663–1696), English conspirator, was educated at Magdalen college, Oxford, becoming a fellow of his college and a Roman Catholic priest. When in 1687 the dispute arose between James II and the fellows of Magdalen over the election of a president, Charnock favoured the first royal nominee, Anthony Farmer, and also the succeeding one, Samuel Parker, bishop of Oxford. Almost alone among the fellows he was not driven out in Nov. 1687, and he became dean and then vice-president of the college under the new regime, but was expelled in Oct. 1688. Residing at the court of the Stuarts in France, or conspiring in England, Charnock and Sir George Barclay appear to have been implicated in the attempt to kill William III near Turnham Green, in Feb. 1696. Barclay escaped, but Charnock was arrested, was tried and found guilty and was hanged on March 18, 1696.

CHARNOCKITE, in petrology a series of igneous rocks (originally described by Sir T. H. Holland) from Madras presidency, southern India, and forming a well-defined petrographic province of Archaean age. The name is derived from that of the founder of Calcutta, Job Charnock, whose tombstone is made of a typical member of the series. The series includes a wide range of rock types from ultrabasic pyroxenites through intermediate types—norites and quartz-hypersthene-diorites—to acid pyroxene-granites. The term charnockite is often specifically reserved for the acid hypersthene-granite. One of the distinguishing features of the series is the recurrence in many members of a strongly pleochroic red-to-green hypersthene. The typical members of the series, however, show other peculiar mineralogical features; namely, the development of *schiller* structures, from the presence of minute plate- or rod-shaped enclosures disposed parallel to definite crystallographic planes or axes. The optical effect of these enclosures is seen in the blue opalescence of the quartz, the milky shimmer of the feldspar and the bronzelike lustre of the rhombic pyroxene. Myrmekitic, microperthitic and antiperthitic structures are common in the feldspars. In the soda-lime feldspars there is a striking tendency to absence of the usual twinning lamellae. The members of the charnockite series frequently show a banded or gneissic structure, now usually interpreted as a flow banding, the result of movement during the epoch of crystallization. Chemically, the series is distinctly subalkaline, with a dominance of iron oxides over magnesia and lime.

The mineralogical characters of the charnockite series, particularly the occurrence of pyroxene in the acid members and the nature of the constituent microperthite, have been ascribed to consolidation from relatively dry magmas: the investigators of some provinces (Adelie Land, Uganda) have, however, interpreted the series as igneous rocks which have acquired their special characters by recrystallization in deep-seated metamorphism.

The various members are of widespread distribution and great petrological importance. In southern India they occur in the Nilgiri hills, the Shevaroys and the western Ghats, extending southward to Cape Comorin and reappearing in Ceylon. They occur in the Archaean shield of Western and South Australia and in Adelie and Enderby Lands, Antarctica. Similar rocks are known from the Ivory coast of west Africa, the eastern part of Ellesmere Land; from the Cortlandt series near Peekskill, N.Y.; and they recur at other localities in the eastern United States and Canada. The most noteworthy occurrences in the northern hemisphere are in southwestern and western Norway, at Egersund and Soggendal, and over a large area in the Bergen and Jotunheimen districts. The majority of the known occurrences of the charnockite series are of Archaean age, but it is probable that the anorthosite-charnockite series of the Bergen-Jotunheimen districts is of lower Palaeozoic (Caledonian) age. (C. E. T.)

CHARNWOOD FOREST, an upland tract in north Leicestershire (*q.v.*), England, southwest of Loughborough. Much of it is barren, though there are extensive tracts of woodland. More than 6,000 ac. are at a height exceeding 600 ft.; the loftiest point, Bardon Hill, is 912 ft.

CHAROLLES, a town of east central France, capital of an arrondissement in the department of Saône-et-Loire, at the confluence of the Semence and Arconce, 39 mi. W.N.W. of Mâcon. Pop. (1946) 2,852.

Charolles was the capital of Charolais, which from the early 14th century gave the title of count to its possessors. The ruins of their castle are on a hill near the town. In 1327 the countship passed by marriage to the house of Armagnac, and in 1390 it was sold to Philip of Burgundy. After the death of Charles the Bold it was seized by Louis XI of France, but in 1493 it was ceded by Charles VIII to Maximilian of Austria. Ultimately passing to the Spanish kings, its possession became disputed, until in 1684 it was assigned to Louis, prince de Condé, a creditor of the king of Spain. It was united to the French crown in 1771. There are stone quarries in the vicinity; the town is also the centre for trade in the famous breed of Charolais cattle.

CHARON, in Greek mythology, the son of Erebus and Nyx (Night). It was his duty to ferry over the Styx and Acheron those souls of the deceased who had duly received the rites of burial, in payment for which service he received an obol, which was placed in the mouth of the corpse. He is probably a product of popular belief, not mentioned in Homer or Hesiod. He is represented as a morose and grisly old man. In Etruscan he is called Charun, and appears as a death demon, armed with a hammer. Finally he came to be regarded as the image of death and the world below. As such he survives in the Charos, or Charontas, of the modern Greeks.

See the classical dictionaries, especially W. H. Roscher's *Lexikon, s.v.*

CHARONDAS, a celebrated lawgiver of Catina in Sicily. His date is uncertain. Some make him a pupil of Pythagoras (*c.* 580–504 B.C.); but all that can be said is that he was earlier than Anaxilaus of Regium (494–476), who abolished his laws, previously in used at Regium. His laws, originally written in verse, were adopted by the other Chalcidic colonies in Sicily and Italy. According to Aristotle there was nothing special about these laws, except that Charondas introduced actions for perjury; but he speaks highly of the precision with which they were drawn up (*Politics*, ii, 12). The legal fragments attributed to him by Stobaeus and Diodorus are of late (neo-Pythagorean) origin.

See Bentley, *On Phalaris*, which (according to B. Niese, *s.v.* in Pauly, *Realencyklopädie*) contains the best account of Charondas; A. Holm, *Geschichte Siciliens*, i; F. D. Gerlach, *Zaleukos, Charondas, und Pythagoras* (1858); also GREEK LAW.

CHARPENTIER, FRANÇOIS (1620–1702), French archaeologist and man of letters, was born in Paris. In his *Excellence de la langue française* (1683) he anticipated Charles Perrault in the famous academical dispute concerning the relative merit of the ancients and moderns. He is credited with a share in the production of the magnificent series of medals that commemorate the principal events of the age of Louis XIV.

CHARRIÈRE, ISABELLE DE (1740–1805), Swiss author, was Dutch by birth, her maiden name being Van Tuyll van Seeroskerken van Zuylen. She married in 1771 her brother's tutor, St. Hyacinthe de Charrière, and settled with him at

Colombier, near Lausanne. Her *Lettres neuchâteloises* (Amsterdam, 1784) offer a simple and attractive picture of French manners. This, with *Caliste, ou lettres écrites de Lausanne* (2 vols. Geneva, 1785–88), was analysed and highly praised by Sainte-Beuve in his *Portraits de femmes* and in vol. iii. of his *Portraits littéraires*. She wrote a number of other novels, and some political tracts; but is perhaps best remembered by her liaison with Benjamin Constant (*q.v.*) between 1787 and 1796.

Her letters to Constant were printed in the *Revue suisse* (April 1844), her *Lettres-Mémoires* by E. H. Gaullieur in the same review in 1857, and all the available material is utilized in a monograph on her and her work by P. Godet, the editor of her *Oeuvres complètes* (3 vols. 1907–09), in his *Madame de Charrière et ses amis* (2 vols., Geneva, 1906).

CHARRON, PIERRE (1541–1603), French philosopher, was born in Paris. He entered the Church, and was appointed preacher in ordinary to Marguerite, wife of Henry IV. of Navarre. At Bordeaux he met Montaigne, whose intimate friend he became.

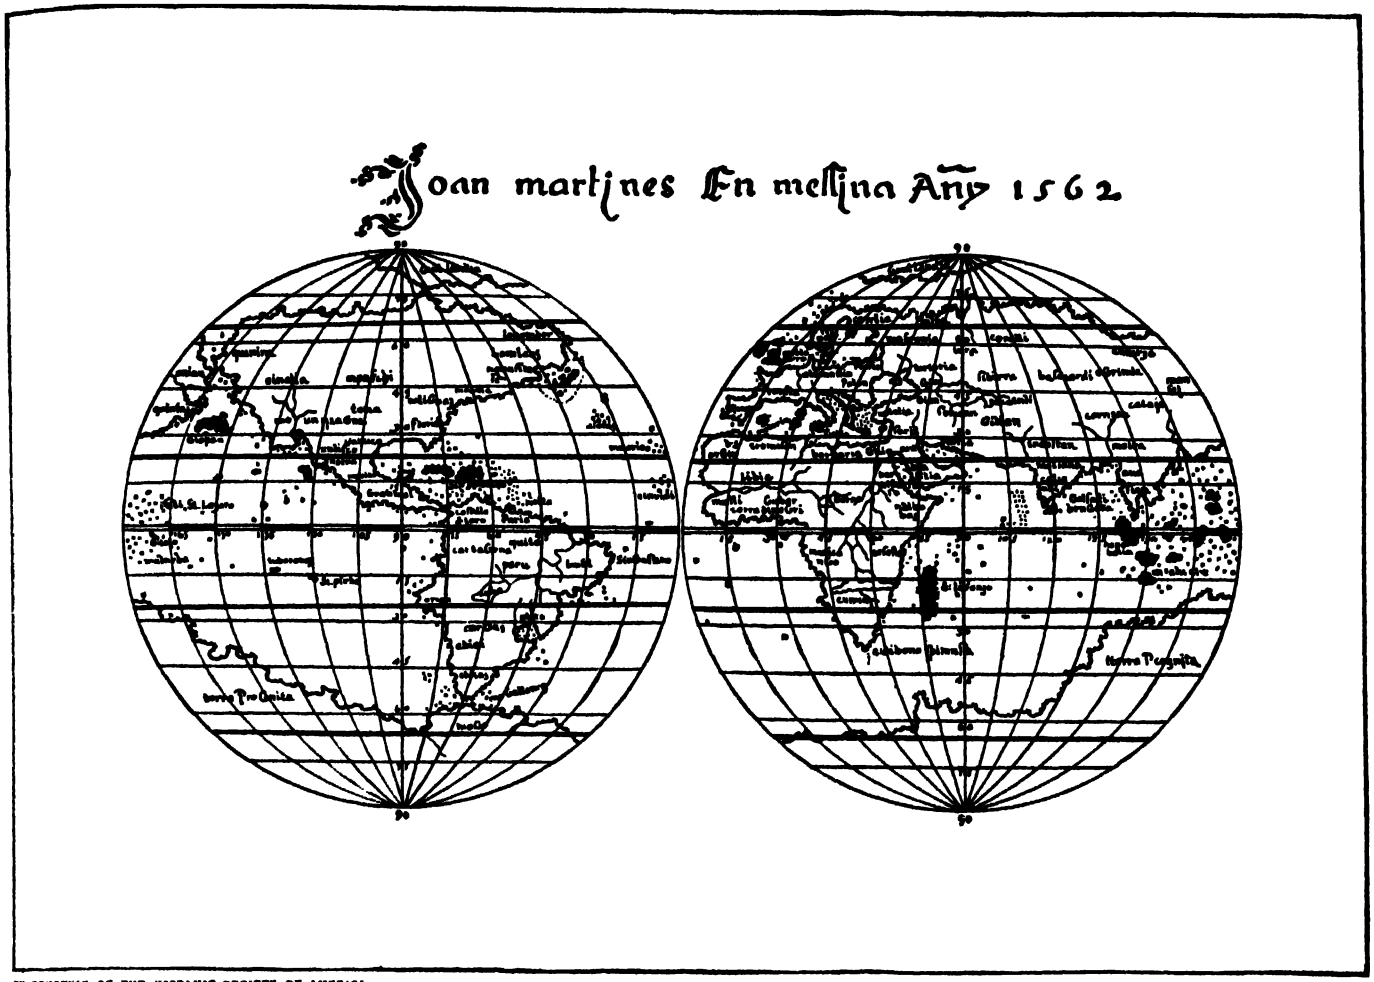
In 1594 Charron published (at first anonymously, afterwards under the name of "Benoit Vaillant, Advocate of the Holy Faith," and also, in 1594, in his own name) *Les Trois Vérités*, in which he seeks to prove that there is a God and a true religion, that the true religion is the Christian, and that the true Church is the Roman Catholic. It is chiefly an answer to the famous Protestant work entitled *Le Traité de l'Église* by Du Plessis Mornay. It was followed in 1600 by *Discours chrestiens*, a book of very eloquent sermons. In 1601 Charron published at Bordeaux the famous *De la sagesse*, a complete popular system of moral philosophy. Usually it is coupled with the Essays of Montaigne, to which the author is under very extensive obligations in it. Charron suddenly stood forth as the representative of the most complete intellectual scepticism. The *De la sagesse* brought upon its author the most violent attacks. It received, however, the warm support of Henry IV. and of the president Pierre Jeannin (1540–1622).

Charron's psychology is sensationalist. With sense all our knowledge commences. The soul, located in the ventricles of the brain, is affected by the temperament of the individual; the dry temperament brings intelligence; the moist, memory; the hot, imagination. The immortality of the soul is the most universal of beliefs, but the most feebly supported by reason. As to man's power of attaining truth, he plainly declares that none of our faculties enable us to distinguish truth from error. On a pessimistic view of human nature Charron founded a moral system that may be summarized as follows: Man comes into the world to endure; let him endure then, and that in silence. Our compassion should be like that of God, who succours the suffering without sharing in their pain. Avoid vulgar errors; cherish universal sympathy. Let no passion or attachment become too powerful for restraint. Follow the customs and laws which surround you. Morality has no connection with religion. Reason is the ultimate criterion.

Charron holds that all religions grow from small beginnings and increase by popular contagion; all teach that God is to be appeased by prayers, presents, vows, but especially, and most irrationally, by human suffering. Each is said by its devotees to have been given by inspiration. In fact, however, a man is a Christian, Jew, or Mohammedan, before he knows he is a man. But while he openly declares religion to be "strange to common sense," the practical result at which Charron arrives is that one is not to sit in judgment on his faith, but to be "simple and obedient," and to allow himself to be led by public authority. Another rule is to avoid superstition, which he defines as the belief that God is like a hard judge, and that therefore He must be flattered and importuned, and won over by pain and sacrifice. True piety is the knowledge of God and of one's self, the latter knowledge being necessary to the former. It leads to spiritual worship; for external ceremony is merely for our advantage, not for His glory. Charron is thus the founder of modern secularism. His political views are neither original nor independent. He pours scorn on the common herd, declares the sovereign to be the source of law, and asserts that popular freedom is dangerous.

A summary and defence of the *Sagesse* appeared in 1606. In 1607 Michel de la Rochemaillet prefixed to an edition of the *Sagesse* a Life. His complete works, with this Life, were published in 1635. An excellent abridgment of the *Sagesse* is given in Tennemann's *Philosophie*, vol. ix.; an edition with notes by A. Duval appeared in 1824.

See H. T. Buckle, *Intro. to History of Civilisation in England*, vol. ii. p. 19 (1869); Abbé Lezat, *De la prédication sous Henri IV.* (1871); Liebscher, *Charron u. sein Werk, De la sagesse* (Leipzig, 1890); J. Owen, *Skeptics of the French Renaissance* (1893); W. E. H. Lecky, *Rationalism in Europe* (new ed. 1910); J. B. Sabrié, *De l'humanisme au rationalisme, Pierre Charron* (1913); J. M. Robertson, *A Short History of Free Thought*, vol. i. p. 480 (3rd. ed. 1915).



CHARRUA, an almost extinct tribe of South American Indians, wild and warlike, formerly ranging over Uruguay and part of southern Brazil. They were dark and heavily built, fought on horses and used the bolas or weighted lasso.

CHART. A chart is a marine map intended specially for the use of the seaman, to assist him to navigate seas and oceans, to sail from port to port and by its means to ascertain the position of a ship with reference to the land, the direction in which to steer, the distance to sail and the dangers to avoid. The water area on charts is studded with numerous small figures; these are the soundings, indicating in fathoms or in feet or in a combination of the two (as shown in the title of the chart) at mean low water spring tides the depth of water at any particular position. Charts show the nature of the sea bottom, the irregularity in its character and give information of the greatest importance to the mariner. No matter how well the land may be surveyed a chart is practically valueless unless soundings are shown.

The British admiralty charts are compiled, drawn and published by the hydrographic department. This department as established under Earl Spencer by an Order in Council in 1795 consisted of the hydrographer, one assistant and one draughtsman. The first hydrographer was Alexander Dalrymple, a gentleman in the East India Company's service; on his supersession in 1808 the office of hydrographer was filled by Captain Thomas Hurd R.N., and has since been held by officers of the Royal Navy, amongst whom may be mentioned Admirals Sir Edward Parry Sir Francis Beaufort and Sir William Wharton. At the present time, 1928, the department consists of the hydrographer, 15 naval assistants, 23 chief cartographers, and cartographers, 57 draughtsmen and 38 clerical staff, apart from the numerous engravers printers, etc., who are employed in the final stages of preparing the work for publication.

Charts prepared by the hydrographic department and published by order of the Lords Commissioners of the Admiralty are compiled from the labours of British naval officers employed in the surveying service, also from surveys made by the Royal Australian Navy, Royal Indian Marine, South African Naval Service and contributions from officers of the Royal navy and mercantile marine. Generally speaking each maritime nation is considered to be responsible for the charting of its own coastal waters and those of its dependencies; the majority of these have efficient and well-organized hydrographic offices, carry out their own surveys and publish charts for the use of seamen. There is a free interchange of hydrographic information as between nations and foreign government charts are utilized and incorporated in various charts and publications produced by the British Admiralty, acknowledgment of the source of the information being made in the title of the chart. Admiralty charts, which are published with the view of meeting the wants of the seaman in all parts of the world, may be classed under five heads, viz., ocean, general, coastal, harbour and physical charts; they are constructed on either mercator or gnomonic projection according to scale and locality. After preparation at the hydrographic department they are engraved on copper plates which thereafter become the original printing medium and which are in constant correction due to the absolute necessity that the latest information should be available.

The depth of the sea is obtained by sounding line, wire or by sonic methods; all soundings are reduced to mean low water spring tides. The times and heights of the tides with the direction and the velocity of the tidal streams are also ascertained. The original surveys drawn by the surveyors afloat are forwarded to the Admiralty and form the basis of the published charts. The ocean and general charts are compiled and drawn at the hydrographic

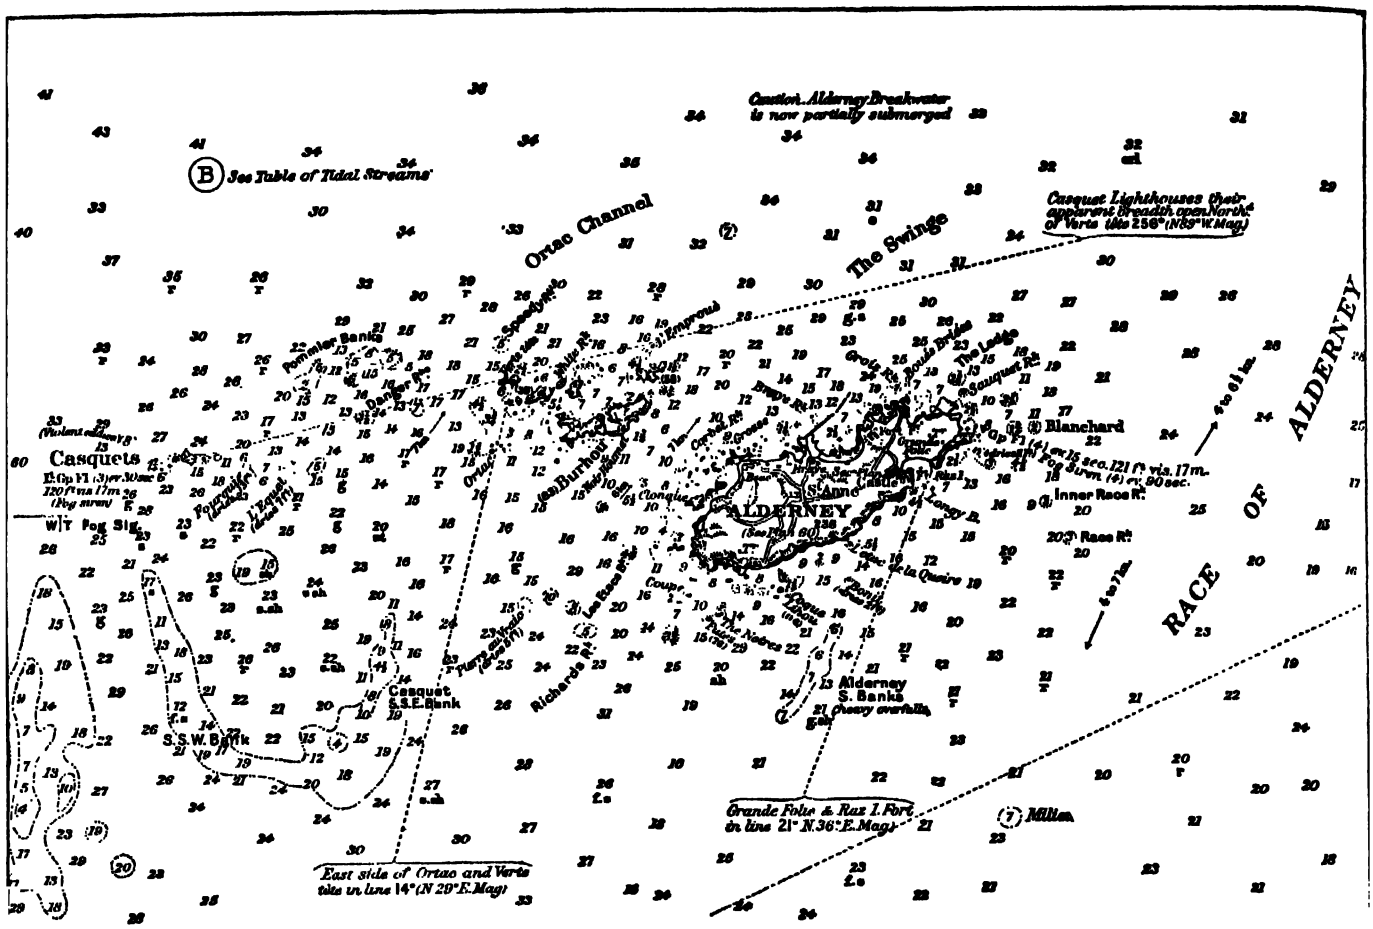
THE WORLD IN TWO HEMISPHERES, FROM THE ATLAS OF 7 CHARTS BY MARTINES OF MESSINA (1562), SHOWING THE EXTENT OF MARITIME DISCOVERY AT THAT DATE. THE AUSTRALIAN CONTINENT WAS STILL "TERRA INCOGNITA."

department; original documents, existing charts, latest surveys and maps have all to be consulted and their compilation requires experience and judgment, for the compiler has to decide what to omit, what to insert, and to arrange the necessary work in such a manner that full information is given to the seaman. A very slight error may lead to great disaster and every symbol on the chart must be delineated with great care. No pains are spared in the effort to lay before the public the labours of the hydrographic surveyors and explorers not only of England, but of all the maritime world, to reduce their various styles into a comprehensive system and to furnish the seaman with a guide of which he may take full advantage. Certain abbreviations are used on charts and are fully described in a special publication.

There are still enormous areas which are unsurveyed or not surveyed in sufficient detail for modern requirements. Charts of these localities are usually drawn in hairline so that the experienced seaman sees at a glance that caution is necessary. The charts issued to the public are correct at the time of publication and are kept corrected for newly reported dangers, changes in character or position of lights and buoys, recent publications of foreign governments, etc., this information being supplied gratis to the public in the Admiralty notices to mariners which are published weekly. Charts are supplemented by the "sailing directions" covering the whole of the navigable portion of the globe, tide tables, light lists, the Admiralty list of wireless time signals, the nautical almanac, distance tables, ocean passages of the world, in which is included information regarding winds and currents, etc.

NAUTICAL SURVEYING



Naval hydrographic surveying has since the termination of the war in 1918 steadily progressed in adopting the latest methods and instruments which have become available to the survevor ashore and afloat. It is not often realized that the hydrographic surveyor has to combine the work of the land surveyor with his own.

Instruments.—The following are the principal instruments required for use in the field and it should be noted that various scientific inventions of great benefit to the surveyor, and of which full advantage has already been taken, were designed and perfected during the World War, 1914–18.

Theodolites (*q.v.*) in current use (1928) are 4 in., 5 in. and 6 in. The majority of these are micrometer theodolites reading to 10 seconds. The use of the theodolite for astronomical and tacheometer work is now universal.

Sextants for observing with stand and artificial horizon are still supplied and improvements in this instrument have been adopted; amalgamated troughs consisting of gold-covered plates on which a thin film of mercury is floated have superseded the old artificial horizon consisting of a mercury bath; the new pattern is far less sensitive to earth tremors. This instrument for work on shore is now to a great extent superseded by other more precise and compact instruments.

Astrolabe à prisme, a very precise instrument, is one of these. It is used for finding position and enables altitudes of any stars at the altitude of 45° or 60° to be observed. The latest form of astrolabe enables observations of stars to be easily and accurately made as follows with the 60° instrument—one step of 7½′ on either side of 60°, that is 3 observations of 59° 52½′, 60°, 60° 07½′ can be taken of one star. With the 45° instrument—four steps of 5′ on either side of 45°, that is 11 observations of 44° 35′, 44° 40′, 44° 45′, 44° 50′, 44° 55′, 45°, 45° 05′, 45° 10′, 45° 15′, 45° 20′, 45° 25′—can be taken of one star. The great advantage of this instrument is that with one setting up of the instrument and without a number of necessary readjustments, as in a theodolite, both time and latitude can be determined, provided of

CHARTS WITH THE PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE, AND OF THE

PORTION OF A CHART OF THE CHANNEL ISLANDS, SHOWING THE ISLAND OF ALDERNEY AND THE DANGEROUS ROCKS KNOWN AS THE CASQUETS. THE FIGURES GIVE SOUNDINGS IN FATHOMS

course that the best and latest method of obtaining error of the time used (*i.e.*, wireless time signals) is adopted.

When it is found necessary to measure bases the hydrographic surveyor uses the 500 ft. steel measuring tape and is provided with the Kew standardization certificate. In surveying abroad where no local triangulation exists, the accurate measurement of a base is recognized as a most important step, second only to a satisfactory base extension. Tacheometers and tacheometer staves marked according to the Admiralty pattern are used for measuring distances up to over 2,000 ft. where extreme accuracy is not necessary. One-metre base range-finders are useful in measuring short bases for plans of harbours, etc., when time or circumstances do not permit of a more accurate method.

Sounding Sextants differ from ordinary sextants in being lighter and handier; the arc which is of brass is cut to minutes, reading to large angles of as much as 140° and fitted with a telescope of high power.

Station Pointer is in constant use for all kinds of plotting: it enables the observer's position to be fixed by two angles between three objects suitably placed, the centre of the instrument indicating the observer's position when set and applied to the plotting sheet.

Sun Signals for reflecting the rays of the sun to distance stations for the purpose of obtaining accurate angles and measurements. The most convenient form is Galton's Sun Signal, which is easy to operate, compact and portable.

In addition *pocket aneroid barometers* for topographical purposes, *prismatic compasses, patent logs, Lucas sounding machines,* both large and small, James's *submarine sentry, tacheometer staves,* etc., are also required. For chart room use *graduated brass scales, steel straight edges, beam compasses* of various lengths, *rectangular protractors, circular brass protractors, mathematical drawing instruments, weights, drawing boards* and *paper* are required.

MARKS AND BEACONS

Every survey must have fixed objects which are first plotted on the sheets, technically known as "points." Natural marks of all kinds are utilized, but these must be supplemented by whitewash marks, cairns, flags, etc. On low coasts and islets flag staffs upwards of 100 ft. high made of several spars lashed together must sometimes be erected in order to get the necessary range of vision. A fixed beacon can be erected in shallow water by constructing a tripod of spars about 45 ft. long. The heads of two of them are lashed together and the heels kept open at a fixed distance by a plank nailed at about 5 ft. above the heels of the spars. These are taken out by three boats and the third tripod leg lashed in position on the boats, the heel in the opposite direction to the other two. The first two legs, weighted, are let go together; using the third leg as a prop, the tripod is hauled into position and secured by guys and by additional weights. A vertical pole with bamboo and flag, the heel being weighted, is lashed to the fork.

Floating Beacons.—These as a rule are specially constructed to carry a flag 12 to 16 ft. square on a bamboo from 30 to 35 ft. long. The beacon is secured to an anchor by means of chain or wire moorings and is visible under good conditions for a distance of about 10 miles. A beacon has been moored by sounding wire in depths of 3,000 fathoms with a weight of 100 lb.

Fixing.—In nautical surveying a thorough knowledge of the principles involved in a station-pointer fix is essential. The method of fixing by two angles between three fixed points is generally known as the "two-circle method," but there are really three circles involved. The "station-pointer" is the instrument used for

plotting fixes. Its construction depends upon the fact that angles subtended by the chord of a segment of a circle measured from any point in its circumference are equal. The lines joining three fixed points form the chords of segments of three circles, each of which passes through the observer's position and two of the fixed points. The more rectangular the angle at which the circles intersect each other, and the more sensitive they are, the better will be the fix; one condition is useless without the other. A circle is "sensitive" when the angle between the two objects responds readily to any small movement of the observer towards or away from the centre of the circle passing through the observer's position and the objects. This is most markedly the case when one object is very close to the observer and the other very distant, but not so when *both* objects are distant. In the accompanying diagrams A, B, C are the objects, and X the observer. Fig. 1 shows the circle passing through C, B and X, cutting the circle ABX at a good angle, and therefore fixing X independently of the circle CAX, which is less sensitive, but being nearly tangential they give no cut with each other. The third cuts both at right angles; it is, however, far less sensitive, and for that reason if the right and left hand objects are both distant the fix must be bad. In such a case as this because the angles CBX, BXA are both so sensitive, and the accuracy of the fix depends on the precision with which the angle CXA is measured, that angle should be observed direct, together with one of the other angles composing it. Fig. 3 represents a case where the points are badly disposed, approaching the condition known as "on the circle," passing through the three points. All three circles cut one another at such a fine angle as to give a very poor fix. The centre of the station-pointer could be moved considerably without materially affecting the coincidence of the legs with the three points. To avoid a bad fix the following rules are safe.

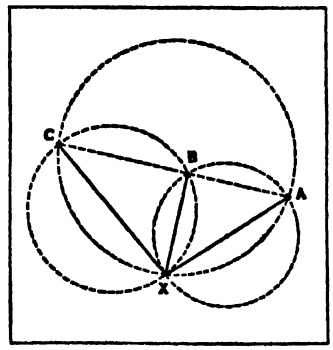


FIG. 1

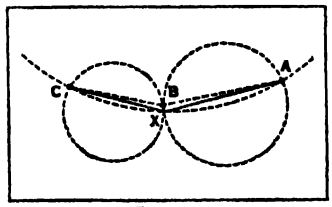

FIG. 2

Choose objects disposed as follows: (a) One outside object distant and the other two near, the angle between the two near objects being not less than 30° or more than 140°. The amount of the angle between the middle and distant object is immaterial. (b) The three objects nearly in a straight line, the angle between any two being not less than 30°. (c) The observer's position being inside the triangle formed by the objects. A fix on the line of two points in transit, with an angle to a third point, becomes more sensitive as the distance between the transit points increases relatively to the distance between the front transit point and the observer; the more nearly the angle to the third point approaches a right angle, and the nearer it is situated to the observer, the better the fix. If the third point is at a long distance, small errors either of observation or plotting will affect the result considerably.

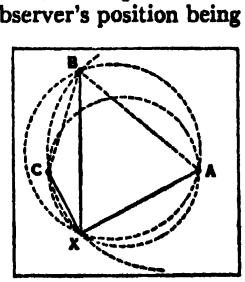

FIG. 3

Tracing-paper answers exactly the same purpose as the station-pointer. The angles are laid off from a centre representing the position, and the lines brought to pass through the points as before. This has often to be used, as when points are close together on a small scale the central part of the station-pointer will often hide them and prevent the use of the instrument. The use of tracing-paper permits any number of angles to different points to be laid down on it, which under certain conditions of fixing is sometimes an advantage.

Bases.—Marine surveys are founded upon triangulation and measured bases of some description, yet when plotted irregularly the system of triangles is not always apparent. The triangulation ranges from the rough triangle of a running survey to the carefully formed triangles of detailed surveys. The measured base for an extended survey is provisional only, the scale resting ultimately mainly upon the astronomical position observed as its extremes. In the case of a plan the base is absolute. The main triangulation establishes a series of points known as main stations, from which and to which angles are taken to fix other stations. A sufficiency of secondary stations enables the detail of the chart to be filled in between them. The points embracing the area to be worked on, having been plotted, are transferred to field boards, upon which the detail of the work in the field is plotted; when complete the work is traced and re-transferred to the plotting sheet, which is then inked in as the finished chart, and is graduated on the gnomonic projection on the astronomical positions of two points situated near opposite corners of the chart.

The kind of base ordinarily used is one measured by a steel tape of 100 or 500 ft. length on flat ground of convenient length, between two points visible from one another and so situated that a triangulation can be extended from them to embrace other points in the survey. The error of the steel tape is noted before leaving the ship, and again on returning, by comparing its length with a standard. The correction so found, also corrections for temperature, sag, etc., are applied to obtain the final result. A masthead angle base is at times useful for small plans, etc., when circumstances do not permit of a base being measured on shore. The height of the masthead to the water line being known the simple calculation necessary to obtain the distance is easily computed.

Astronomical Base.—The difference of latitude between two stations visible from each other and nearly in the same meridian, combined with their true bearings, gives an excellent base for an extended triangulation; the only drawback to it is the effect of local attraction of masses of land in the vicinity on the pendulum, or, in other words, on the mercury in the artificial horizon. The base stations should be as far apart as possible, in order to minimize the effect of any error in the astronomical observations. The observation spots would not necessarily be actually at the base stations, which would probably be situated on summits at some little distance in order to command distant views. In such cases each observation spot would be connected with its corresponding base station by a subsidiary triangulation, a short base being measured for the purpose. If possible, the observation spots should be east or west of the mountain station from which the true bearings are observed.

If the base stations A and B are so situated that by reason of distance or of high land intervening they are invisible from one another, but both visible from some main station C between them, when the main triangulation is completed, the ratio of the sides AC, BC can be determined. From this ratio and the observed angle ACB, the angles ABC, BAC can be found. The true bearing of the lines AC or BC being known, the true bearing of the base stations A and B can be deduced.

Extension of Base.—A base of any description is seldom long enough to plot from directly, and in order to diminish errors of plotting it is necessary to begin on the longest side possible so as to work inwards. A short base measured on flat ground will give a better result than a longer one measured over inequalities, provided that the triangulation is carefully extended by means of judiciously selected triangles, great care being taken to plumb the centre of each station. To facilitate the extension of the base in as few triangles as possible, the base should be placed so that there are two stations, one on each side of it, subtending angles at them of from 30° to 40°, the distances between which, on being calculated in the triangles of the quadrilateral so formed, will constitute the first extension of the base. Similarly, two other stations placed one on each side of the last two will form another quadrilateral, giving a yet longer side, and so on.

Main Triangulation.—The angles to be used in the main triangulation scheme must be very carefully observed and the theodolite placed exactly over the centre of the station Main

angles are usually repeated several times by resetting the vernier at intervals equidistant along the arc, in order to eliminate instrumental errors as well as errors of observation. The selection of an object suitable for a zero is important. It should, if possible, be another main station at some distance, but not so far or so high as to be easily obscured, well defined, and likely to be permanent. Angles to secondary stations should be repeated. Rough sketches from all stations with angles are of great assistance in identifying objects from different points of view.

False Station.—When the theodolite cannot for any reason be placed over the centre of a station, if the distance be measured and the theodolite reading of it be noted, the observed angles may be reduced to what they would be at the centre of the station. False stations have frequently to be made in practice; a simple rule to meet all cases is of great assistance to avoid the possibility of error in applying the correction with its proper sign It may very easily be found as follows.

Rule.—Put down the theodolite reading which it is required to correct (increased if necessary by 360°), and from it subtract the theodolite reading of the centre of the station. Call this remainder θ. With θ as a "course" and the number of feet from the theodolite to the station as a "distance," enter the traverse table and take out the greater increment if θ lies between 45° and 135°, or between 225° and 315°, and the lesser increment for other angles. The accompanying diagram (fig. 4) will assist the memory. Refer this increment to the "table of subtended angles by various lengths at different distances" (using the distance of the object observed) and find the corresponding correction in arc, which mark + or − according as θ is under or over 180°. Apply this correction to the observed theodolite angle. A "table of subtended angles" is unnecessary if the formula

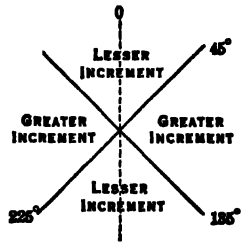

FIG. 4

$$\text{Angle in seconds} = \frac{\text{Number of feet subtended} \times 34}{\text{Distance of object in sea miles}}$$

be used instead.

The difference of the reciprocal true bearings between two stations is called the "convergency." The formula for calculating it is: Conv. in minutes = dist. in sea miles × sin. Merc. bearing × tan. mid. lat. Whenever true bearings are used in triangulation, the effect of convergency must be considered and applied. In north latitudes the southerly bearing is the greater of the two, and in south latitudes the northerly bearing. The Mercatorial bearing between two stations is the mean of their reciprocal true bearings.

Triangulated Coast Survey.—After a preliminary run over the ground to note suitable positions for stations on prominent headlands, islands and summits not too far back from the coast, and, if no former survey exists, to make at the same time a rough plot of them by compass and patent log, a scheme must be formed for the main triangulation with the object of enclosing the whole survey in as few triangles as possible, regard being paid to the limit of vision of each station due to its height, to the existing meteorological conditions, to the limitations imposed by higher land intervening, and to its accessibility. The triangles decided upon should be well-conditioned, taking care not to introduce an angle of less than 30° to 35°, which is only permissible when the two longer sides of such a triangle are of nearly equal length, and when the determination of this length does not depend on the short side. In open country the selection of stations is a comparatively easy matter, but in country densely wooded the time occupied by a triangulation is largely governed by the judicious selection of stations quickly reached, sufficiently elevated to command distant views, and situated on summits capable of being readily cleared of trees in the required directions, an all-round view being, of course, desirable though not always attainable. The positions of secondary stations will also generally be decided upon during the preliminary reconnaissance. The object of these stations is to break up the large primary triangles into triangles of smaller size, dividing up the distances between the primary stations into suitable lengths; they are selected with a view to greater accessibility than the latter, and should therefore usually be near the coast and at no great elevation. Upon angles from these will depend the position of the coastline marks, to be erected and fixed as the detailed survey of each section of the coast is taken in hand. The nature of the base to be used, and its position in order to fulfil the conditions specified under the head of *Bases* must be considered, the base when extended forming a side of one of the main triangles. It is immaterial at what part of the survey the base is situated, but if it is near one end, a satisfactory check on the accuracy of the triangulation is obtained by comparing the length of a side at the other extreme of the survey, derived by calculation through the whole system of triangles with its length deduced from a check base measured in its vicinity. It is generally a saving of time to measure the base at some anchorage or harbour that requires a large scale plan. The triangulation involved in extending the base to connect it with the main triangulation scheme can thus be utilized for both purposes, and while it is being calculated and plotted the survey of the plan can be proceeded with. The bearings are observed at both ends of the survey and at other selected stations and the results subsequently compared. Astronomical observations for latitude and longitude are obtained at observation spots near the extremes of the survey and are connected with the primary triangulation; they are usually disposed at intervals of from 100 to 150 m., and thus errors due to a triangulation carried out with theodolites of moderate diameter do not accumulate to any serious extent.

Calculating the Triangulation.—The triangles as observed being tabulated the angles of each triangle are corrected to bring their sum to exactly 180°. We must expect to find errors in the triangles, but under favourable conditions they will only amount to a few seconds. In distributing the errors we must consider the conditions under which the angles were observed; failing any particular reason to assign a larger error to one angle than to another, the error must be divided equally. The various quadrilaterals and polygons are then adjusted to make the whole triangulation as rigid as possible and bring the whole network into agreement. The length of base being determined, the sides of all the triangles involved are calculated by the ordinary rules of trigonometry. Starting from the true bearing observed at one end of the survey, the bearing of the side of each triangle that forms the immediate line of junction from one to the other is found by applying the angles necessary for the purpose in the respective triangles, not forgetting to apply the convergency between each pair of stations when reversing the bearings. The bearing of the final side is then compared with the bearing obtained by direct observation at that end of the survey. The difference is principally due to accumulated errors in the triangulation; half of the difference is then applied to the bearing of each side. Convert these true bearings into Mercatorial bearings by applying half the convergency between each pair of stations. With the lengths of the connecting sides found from the measured base and their Mercatorial bearing, the Mercatorial bearing of one observation spot from the other is found by middle latitude sailing. Taking the observed astronomical positions of the observation spots and first reducing their true difference longitude to departure, as measured on a spheriod from the formula

$$\text{Dep.} = \text{T.D. long.} \frac{\text{No. ft. in 1 m. of long.}}{\text{No. ft. in 1 m. of lat.}}$$

then with the d. lat. and dep. the Mercatorial true bearing and distance between the observation spots is calculated by middle latitude sailing, and compared with that by triangulation and measured base. To adjust any discrepancy, it is necessary to consider the probable error of the observation for latitude and meridian distance; within those limits the astronomical positions may safely be altered in order to harmonize the results; it is more important to bring the bearings into close agreement than the

distance. From the amended astronomical position the Mercatorial true bearings and distance between them are re-calculated. The difference between this Mercatorial bearing and that found from the triangulation and measured base must be applied to the bearing of each side to get the final corrected bearings, and to the logarithm of each side of the triangulation as originally calculated must be added or subtracted the difference between the logarithms of the distance of the amended positions of the observation spots and the same distance by triangulation.

Calculating Intermediate Astronomical Positions.—The latitude and longitude of any intermediate main station may now be calculated from the finally corrected Mercatorial true bearings and lengths of sides. The difference longitude so found is what it would be if measured on a true sphere, whereas we require it as measured on a spheroid, which is slightly less. The correction $= \text{d. long.} \frac{\cos^2 \text{mid. lat.}}{150}$ must therefore be subtracted; or the difference longitude may be found direct from the formula $\text{Dep.} \frac{\text{No. ft. in 1 m. of lat.}}{\text{No. ft. in 1 m. of long.}}$. From the foregoing it is seen that in a triangulation for hydrographical purposes both the bearings of the sides and their lengths ultimately depend almost entirely upon the astronomical observations at the extremes of the survey; the observed true bearings and measured base are consequently more in the nature of checks than anything else. It is obvious, therefore, that the nearer together the observation spots, the greater effect will a given error in the astronomical positions have upon the length and direction of the sides of the triangulation, and in such cases the bearings as actually observed must not be altered to any large extent when a trifling change in the astronomical positions might perhaps effect the required harmony. For the reasons given under *Astronomical Base*, high land near observation spots may cause very false results, which may often account for discrepancies when situated on opposite sides of a mountainous country.

Plotting.—Great care is requisite in projecting on paper the points of a survey. The paper should be allowed to stretch and shrink as it pleases until it comes to a stand, being exposed to the air for four or five hours daily, and finally well flattened out by being placed on a table with drawing boards placed over it heavily weighted. If the triangulation and co-ordinates have been calculated beforehand throughout, it is more advantageous to plot by co-ordinates or distances rather than by chords. The main stations are thus got down in less time and with less trouble, but these are only a small proportion of the points to be plotted, and if chords or distances are used long lines must be ruled between the stations as zeros for plotting other points by chords. In ruling these lines care must be taken to draw them exactly through the centre of the pricks denoting the stations, but, however, carefully drawn, there is liability to slight error in any line projected to a point lying beyond the distance of the stations between which the zero line is drawn. In plotting by distances, therefore, all points that will subsequently have to be plotted by chords should lie well within the area covered by the main triangulation. Three distances must be measured to obtain an intersection of the arcs cutting each other at a sufficiently broad angle; the plotting of the main stations once begun must be completed before distortion of the paper can occur from change in the humidity of the atmosphere. Plotting, whether by distance or by chords, must be begun on as long a side as possible, so as to plot inwards, or with decreasing distances. In plotting by chords it is important to remember in the selection of lines of reference (or zero lines), that that should be preferred which makes the smallest angle with the line to be projected from it, and of the angular points those nearest to the object to be projected from them.

Irregular Methods of Plotting.—In surveys for the ordinary purposes of navigation, it may happen that a regular system of triangulation cannot be carried out; the judicious use of the ship in such cases is often essential, and with proper care excellent results may be obtained. A few examples will best illustrate some of the methods used, but circumstances vary in every survey. Fixing a position by means of the "back-angle" is one of the most ordinary expedients. Angles having been observed at A, to the station B, and certain other fixed points of the survey, C and D for instance; if A is shot up from B, at which station angles to the same fixed points have been observed, then it is not necessary to visit those points to fix A. For instance, in the triangle ABC, two of the angles have been observed, and therefore the third angle at C is known (the three angles of a triangle being equal to 180°), and it is called the "calculated or back-angle from C." A necessary condition is that the receiving angle at A, between any two lines (direct or calculated), must give a good cut; also the points from which the "back-angles" are calculated should not be situated at too great distances from A, relatively to the distance between A and B. A station may be plotted by laying down the line to it from one station, and then placing on tracing-paper a number of the angles taken at it, including the angle to the station from which it has been observed. If the points to which angles are taken are well situated, a good position is then obtained. Sometimes the main stations must be carried on with a point plotted by only two angles. An effort must be made to check this subsequently by getting an "angle back" from stations dependent upon it to some old well-fixed point; failing this, two stations being plotted with two angles, pricking one and laying down the line to the other will afford a check. A well-defined mountain peak, far inland and never visited, when once it is well fixed is often invaluable in carrying on an irregular triangulation, as it may remain visible when all other original points of the survey have disappeared, and "back-angles" from it may be continually obtained, or it may be used for plotting on true bearing lines of it. In plotting the true bearing of such a peak, the convergency must be found and applied to get the reversed bearing, which is then laid down from a meridian drawn through it; of the reversed bearing of any other line already drawn through the peak being known, it may simply be laid down with that as a zero. A rough position of the spot from which the true bearing was taken must be assumed in order to calculate the convergency. Fig. 5 will illustrate the foregoing remarks. A and B are astronomical observation spots at the extremes of a survey, from both of which the high inaccessible peak C is visible. D, E, F are intermediate stations; A and D, D and E, E and F, F and B being respectively visible from each other. G is visible from A and D, and C is visible from all stations. The latitudes of A and B and meridian distance between them being determined, and the true bearing of C being observed from both observation spots, angles are observed at all the stations. Calculating the spheroidal correction from the formula, correction = d. long. $\frac{\cos^2 \text{mid. lat.}}{150}$ and adding it to the true (or chronometric) d. long. between A and B to obtain the spherical d. long.; with this spherical d. long. and the d. lat., the Mercatorial true bearing and distance is found by middle latitude sailing (which is an equally correct but shorter method than by spherical trigonometry, and may be safely used when dealing with the distances usual between observation spots in nautical surveys). The convergency is also calculated, and the true bearing of A from B and B from A are thus determined. In the plane triangle ABC the angle A is the difference between the calculated bearing of B and the observed bearing of C from A. The distance AB having been calculated, the side AC is found. Laying down AC on the paper on the required scale, D is plotted on its direct shot from A, and on the angle back from C, calculated in the triangle ACD. G is plotted on the direct shots from A and D, and on the angle back from C, calculated either in the triangle ACG or GCD.

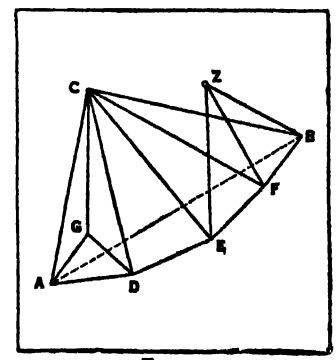

FIG. 5.

The perfect intersection of the three lines at G assures these four points being correct. E. F and B are plotted in a similar manner. The points depend on calculated angles, and except for the first four points we have no check, either on the accuracy of the angles observed in the field or on the plotting. Another well-defined object in such a position, for instance as Z, visible from three or more stations, would afford the necessary check, if lines laid off to it from as many stations as possible gave a good intersection. If no such point, however, exists a certain degree of check on the angles observed is derived by applying the sum of all the calculated angles at C to the true bearing of A from C (found by reversing observed bearing of C from A with convergency applied), which will give the bearing of B from C. Reverse this bearing with convergency applied, and compare it with the observed bearing of C from B. If the discrepancy is but small, it will be a strong presumption in favour of the substantial accuracy of the work. If the calculated true bearing of B from A be now laid down, it is very unlikely that the line will pass through B, but this is due to the discrepancy which must always be expected between astronomical positions and triangulation. If some of the stations between A and B require to be placed somewhat closely to one another, it may be desirable to obtain fresh true bearings of C instead of carrying on the original bearing by means of the calculated angle. In all cases of irregular plotting the ship is very useful, especially if she is moored taut without the swivel, and angles are observed from the bow. Floating beacons also assist an irregular triangulation.

Sketch Surveys.—Surveys of various degrees of accuracy are included among sketch surveys. The roughest description is the running survey, when the work is done by the ship steaming along the coast, fixing points, and sketching in the coast-line by bearings and angles, relying for her position upon her courses and distances as registered by patent log, necessarily regardless of the effect of wind and current and errors of steering. At the other extreme comes the modified running survey, which in point of practical accuracy falls little short of that attained by irregular triangulation. Some of these modifications will be briefly noticed. A running survey of a coast-line between two harbours, that have been surveyed independently and astronomically fixed, may often be carried out by fixing the ship on the points already laid down on the harbour surveys and shooting up prominent intermediate natural objects, assisted by theodolite angles. Theodolite lines to the ship and floating beacons suitably placed, materially increase the value of any such work. A sketch survey of a coast upon which it is impossible to land may be carried out by dropping beacons at intervals of about 8 m., well out from the land and placed abreast prominent natural objects called the "breastmarks," which must be capable of recognition from the beacons anchored off the next "breastmark" on either side. The distance between the beacons is found by running a patent log both ways, noting the time occupied by each run; if the current has remained constant, a tolerably good result can be obtained. At the first beacon, angles are observed between the second beacon and the two "breastmarks," and "intermediate" mark, and any other natural object which will serve as "points." At the second beacon, angles are observed between the first beacon and the same objects as before. Plotting on the line of the two beacons as a base, all the points observed can be pricked in on two shots. At a position about midway between the beacons, simultaneous angles are observed to all the points and laid off on tracing-paper, which will afford the necessary check, and the foundation is thus laid for filling in the detail of coast-line, topography, and soundings off this particular stretch of coast. Each section of coast is complete in itself on its own base; the weak point lies in the junction of the different sections, as the patent log bases will not agree precisely, and the scales of adjacent sections are liable to be slightly different. This is obviated, as far as possible, by fixing on the points of one section and shooting up those of another, which will check any great irregularity of scale creeping in. The bearing is preserved by getting occasional true bearing lines at the beacons of the most distant point visible. In all cases of using angles from the ship under weigh, several assistants are necessary, so that the principal angles may be taken simultaneously, the remainder being connected immediately afterwards with zeros involving the smallest possible error due to the ship not being absolutely stationary, these zeros being included amongst the primary angles. When close to a beacon, if its bearing is noted and the distance in feet obtained from its elevation, the angles are readily reduced to the beacon itself. Astronomical positions by twilight stars keep a check upon the work.

Sketch Surveys by Compass Bearings and Vertical Angles.—In the case of an island culminating in a high, well-defined summit visible from all directions, a useful and accurate method is to steam round it at a sufficient distance to obtain a true horizon, stopping to make as many stations as may be desirable, and fixing by compass bearing of the summit and its vertical angle. The height is roughly obtained by shooting in the summit, from two positions on a patent log whilst approaching it. With this approximate height and Lecky's vertical danger angle tables, each station may be plotted on its bearing of the summit. From these stations the island is shot in by angles between its tangents and the summit, and angles to any other natural features, plotting the work as we go on any convenient scale which must be considered only as provisional. On completing the circuit of the island, the true scale is found by measuring the total distance in inches on the plotting sheet from the first to the last station, and dividing it by the distance in miles between them as shown by patent log. The final height of the summit bears to the rough height used in plotting the direct proportion of the provisional scale to the true scale. This method may be utilized for the sketch survey of a coast where there are well-defined peaks of sufficient height at convenient intervals, and would be superior to an ordinary running survey. From positions of the ship fixed by bearings and elevation of one peak, another farther along the coast is shot in and its height determined; this second peak is then used in its turn to fix a third, and so on. Lecky's tables will show what effect an error of say 1′ in altitude will produce for any given height and distance, and the limits of distance must depend upon this consideration.

Surveys of Banks out of Sight of Land.—On striking shoal soundings unexpectedly, the ship may either be anchored at once and the shoal sounded by boats starring round her, using compass and masthead angle; or if the shoal is of large extent and may be prudently crossed in the ship, it is a good plan to get two beacons laid down on a bearing from one another and patent log distance of 4 or 5 m. With another beacon (or mark-boat, carrying a large black flag on a bamboo 30 ft. high) fixed on this base, forming an equilateral triangle, and the ship anchored as a fourth point, soundings may be carried out by the boats fixing by station-pointer. The ship's position is determined by observations of twilight stars.

Coastlining.—In a detailed survey the coast is sketched in by walking along it, fixing and plotting at intervals. Fixed marks along the shore afford a check on the minor coast-line fixes. When impracticable to fix in the ordinary way subtense methods are used. Greater accuracy is obtained if the work is plotted on the field board at once; this is not always possible but the angles being registered and sketches made of the intervening coast the work may be plotted afterwards. It is with the high water line that the coast-liner is chiefly concerned, delineating its character according to the accepted symbols. The sounder is responsible for the position of the dry line at low water. Heights of cliffs, rocks, islets, etc., must be inserted either from measurement or from the formula,

$$\text{Height in feet} = \frac{\text{Angle of elevation in seconds} \times \text{distance in miles}}{34},$$

and details of topography near the coast, including roads, houses and enclosures must be shown. Rocks above water or on which the sea breaks should be fixed. Coast-line may be sketched from a boat off shore by fixing and shooting up natural objects from selected positions.

Soundings.—The most important feature of a chart is the sounding, and the more complete this is the better is the survey

Small scale surveys are apt to be misleading; such a survey may appear closely sounded but in reality it sometimes fails to disclose indications of shoal water. Sounding may be commenced as soon as sufficient points are plotted; but off an intricate coast it is better to get the coast-line in first. Lines of soundings are run by the boats perpendicular to the coast, at a distance apart governed by the scale; five lines to the inch is about as close as can be run without overcrowding. The distance apart will vary with the depth of water and the nature of the coast; for instance a rocky coast with shallow water off it will need closer examination than a steep coast. The prolongation of a point under water will require special care to ensure the fathom lines being correct. When soundings begin to decrease to seaward intermediate lines or lines crossing those previously run should be obtained. If possible lines of soundings should be run on transits; these may generally be picked up by fixing when on the required line, noting the angle on the protractor between the line and some fixed mark on the field board, then placing the angle on the sextant and noting what objects intersect at that angle. On large scale surveys it may be necessary to place transit marks in the required positions. The boat is fixed by two angles, with an occasional third angle as a check; the distance between the fixes is dependent upon the scale of the chart and the rapidity with which the depth alters; the 3, 6 and 10 fathom lines should always be fixed, allowing roughly for the tidal reduction. The nature of the bottom must be taken every few casts and recorded. It is best to plot each fix on the sounding board at once, joining the fixes by straight lines and numbering them for identification. The tidal reduction being obtained, the reduced soundings corrected for any lead line error are written in the field-book in red underneath each sounding as originally noted; they are then placed in their proper position on the board between the fixes. Suspicious ground should be closely examined; a small buoy anchored on the shoal is useful to guide the boat while trying for the least depth. Sweeping for a reported pinnacle rock should be resorted to when sounding fails to discover it. Local information from fishermen and others is often of value. Up to depths of about 15 fathoms the hand lead-line is used from the boats, but beyond that depth the Lucas machine for wire effects a great saving of time and labour. The deeper soundings of a survey are usually obtained from the ship, but steamboats with wire sounding machines often assist very materially. By the aid of a steam winch, a 100-lb. lead is hove forward to the end of the lower boom rigged out, from which it is dropped by reversing the winch, soundings of 50 fathoms may be picked up from the sounding platform aft, whilst going at a speed of 5 to 6 knots. In deeper water it is quicker to stop the ship and sound from aft with the wire sounding machine. In running lines of soundings on and off shore, it is essential to be able to fix as far from the land as possible. Angles will be taken from aloft for this purpose, and floating beacons dropped in selected positions will be of assistance. A single fixed point on the land used in conjunction with two beacons suitably placed will give an admirable fix.

Echo Sounding.—This method of obtaining the depth is likely to prove of increasing value as time goes on and its efficiency becomes known. The principle is that an electric impulse is transmitted from the bottom of a ship, strikes the bed of the ocean and is reflected as an echo which is received by a hydrophone. The sound waves are sent out at fixed intervals and the echo is heard in telephone receivers connected with the hydrophone. The velocity of sound in water being known the depth can be calculated provided the time interval is accurately measured. A hand wheel, working a depth scale and connected with the telephonic gear is manipulated until echoes are heard in the receiver; the depth can then be read off the circular scale.

The Admiralty echo sounding apparatus shallow water type is designed to register depths of from 3 to 120 fathoms; for greater depths a modified form of echo gear is utilized. The saving of time is particularly noticeable where great depths are being obtained, the echo gear giving a result in a few seconds, whereas with a wire sounding machine the operation is a lengthy proceeding often occupying more than an hour. The disadvantage of echo sounding is that it is impossible to determine the nature of the bottom by this means and where a survey is in progress this must be obtained with the lead.

Vigias.[1]—A certain percentage of *vigias* which are reported and placed on the charts eventually turn out to have no existence, but before it is possible to expunge them the area has to be examined. Submarine banks rising from great depths necessarily stand on bases many square miles in area. Of recent years our knowledge of the angle of slope that may be expected to occur at different depths has been much extended. From depths upwards of 2,000 fathoms the slope is so gradual that a bank could hardly approach the surface in less than 7 m. from such a sounding; therefore anywhere within an area of at least 150 sq.m. all round a bank rising from these depths, a sounding must show some decided indications of a rise in the bottom. Under such circumstances, soundings at intervals of 7 m., and run in parallel lines 7 m. apart, enclosing areas of only 50 sq.m. between any four adjacent soundings, should clear up the ground and lead to the discovery of any shoal. As the depth decreases the angle of slope rapidly increases, and a shoal might occur within three-quarters of a mile or even half a mile of such a sounding as 500 fathoms. An appreciation of these facts will indicate the distance apart at which it is proper to obtain soundings. Contour lines will show in which direction to prosecute the search. When once a decided indication is found, it is not difficult to follow it up by paying attention to the contour lines as developed by successive soundings. Discoloured water, ripplings, fish jumping or birds hovering about may assist in locating a shoal, but the submarine sentry towed at a depth of 40 fathoms is here most valuable, and may save hours of hunting. Reports being more liable to errors of longitude than of latitude, a greater margin is necessary in that direction. Long parallel lines east and west are preferable, but the necessity of turning the ship more or less head to wind at every sounding makes it desirable to run the lines with the wind abeam, which tends to disturb the dead reckoning least. The current should be allowed for in shaping the course to preserve the parallelism of the lines, but the less frequently the course is altered the better. A good position should be obtained at morning and evening twilight by pairs of stars on opposite bearings, the lines of position of one pair cutting those of another pair nearly at right angles. The dead reckoning should be checked by lines of position from observations of the sun about every two hours throughout the day, preferably whilst a sounding is being obtained and the ship stationary.

Tides.—The datum for reduction of soundings is mean low-water springs, the level of which is referred to a permanent bench mark in order that future surveys may be reduced to the same datum level. Whilst sounding is going on the height of the water above this level is observed by a tide gauge. The time of high-water at full and change, called the "establishment," and the heights to which spring and neap tides respectively rise above the datum are also required. It is seldom that a sufficiently long series of observations can be obtained for their discussion by harmonic analysis, and therefore the graphical method is preferred. A good portable automatic tide gauge suitable for all requirements is much to be desired.

Tidal streams and surface currents are observed from the ship or boats at anchor by means of a current log. An alternative method is to follow a drifting buoy fixing the position at intervals. Tidal streams often run for some hours after high or low water by the shore; it is important to determine whether the change of stream occurs at a regular time of the tide.

Undercurrents are also of importance. A deep-sea current meter devised (1876) by Lieutenant Pillsbury, U.S.N., has been used with success on many occasions, notably in the investigation of the Gulf Stream. More recent developments of deep-sea current meters are the Ekman, Jacobsen, Sverdrup, Woolaston and Carruthers instruments. The instrument is lowered to the required depth and brought into action by a messenger, travelling down the supporting line and operating a lever which sets the instrument

[1]Spanish word meaning "look-out," used of marks on the chart signifying obstruction to navigation.

free, or some similar contrivance. On the completion of the necessary interval the meter is locked whilst still below the surface, hauled up and examined. The time during which the instrument has been working at the required depth is known and the direction and strength of the current can be determined from the mechanical arrangements.

Topography.—Generally speaking the topographical features should be delineated as far back as the skyline viewed from seaward, in order to assist the navigator to recognize the land. Summits of hills, conspicuous spurs, cliffs, etc., are fixed and their heights determined by theodolite elevations or depressions to and from positions where the height above the water is known. The shape is delineated by contour lines sketched by eye, assisted by an aneroid barometer. In wooded country much of the topography may have to be determined from the ship; sketches from different positions at anchor with the necessary angles to fix the features give a fair idea of the general lie of the country.

Latitudes.—Circum-meridian altitudes of stars observed by sextant in the artificial horizon is one of the methods adopted for observations for latitudes. Arranged in pairs of nearly the same altitude north and south of zenith, the mean of each pair give a result from which instrumental and personal errors and errors due to atmospheric conditions are eliminated. The mean of several such pairs should have a probable error of not more than $\pm 1''$. The observations of each star should be confined to within 5 or 6 minutes on either side of the meridian. Two stars selected to "pair" should pass the meridian within an hour of each other, and should not differ in altitude more than 2° or 3°. Artificial horizon roof error is eliminated by always keeping the same end of the roof towards the observer; when observing a single object, as the sun, the roof must be reversed when half way through the observations. The observations are reduced to the meridian by Raper's method. When pairs of stars are not observed, circum-meridian altitudes of the sun may be resorted to, but being observed on one side of the zenith only, none of the errors to which all observations are liable can be eliminated.

Chronometer Errors.—Equal altitudes of sun or stars by sextant and artificial horizon are employed to obtain chronometer errors. Six sets of eleven observations, A.M. and P.M., observing both limbs of the sun, should give a result which, under favourable conditions of latitude and declination, may be expected to vary less than two-tenths of a second from the normal personal equation of the observer. Stars give equally good results. In high latitudes sextant observations diminish in value owing to the slower movement in altitude. In the case of the sun all the chronometers are compared with the "standard" at apparent noon; the comparisons with the chronometer used for the observations on each occasion of landing and returning to the ship are worked up to noon. In the case of stars, the chronometer comparisons on leaving and again on returning are worked up to an intermediate time. A convenient system, which retains the advantage of the equal altitude method, whilst avoiding the necessity of waiting some hours for the P.M. observation, is to observe two stars at equal altitudes on opposite sides of the meridian, and, combining the observations, treat them as relating to an imaginary star having the mean right ascension and mean declination of the two stars selected, which should have nearly the same declination and should differ from 4^h to 8^h in R.A.

Meridian Distances.—The error of chronometer on mean time of place being obtained, the local time is transferred from one observation spot to another by the ship carrying usually eight box chronometers. The best results are found by using travelling rates, which are deduced from the difference of the errors found on leaving an observation spot and returning to it; from this difference is eliminated that portion which may have accumulated during an interval between two determinations of error at the other, or any intermediate, observation spot. A travelling rate may also be obtained from observations at two places, the meridian distance between which is known; this rate may then be used for the meridian distance between places observed during the passage. Failing travelling rates, the mean of the harbour rates at either end must be used. The same observer, using the same instrument, must be employed throughout the observations of a meridian distance.

If the telegraph is available, it should be used. The error on local time at each end of the wire is obtained, and a number of telegraphic signals are exchanged between the observers, an equal number being transmitted and received at either end. The local time of sending a signal from one place being known and the local time of its reception being noted, the difference is the meridian distance. The retardation due to the time occupied by the current in travelling along the wire is eliminated by sending signals in both directions. The relative personal equation of the observers at either end, both in their observations for time, and also in receiving and transmitting signals, is eliminated by changing ends and repeating the operations. If this is impracticable, the personal equations should be determined and applied to the results. Chronometers keeping solar time at one end of the wire, and sidereal time at the other end, materially increase the accuracy with which signals can be exchanged, for the same reason that comparisons between sidereal clocks at an observatory are made through the medium of a solar clock. Time by means of the sextant can be so readily obtained, and within such small limits of error, by skilled observers, that in hydrographic surveys it is often employed; but if transit instruments are available, and sufficient time can be devoted to erecting them properly, the value of the work is greatly enhanced.

True Bearings are obtained on shore by observing with theodolite the horizontal angle between the object selected as the zero and the sun, taking the latter in each quadrant as defined by the cross-wires of the telescope. The altitude may be read on the vertical arc of the theodolite; except in high latitudes, where a second observer with sextant and artificial horizon are necessary, unless the precise errors of the chronometers are known, when the time can be obtained by carrying a pocket chronometer to the station. The sun should be near the prime vertical and at a low altitude; the theodolite must be very carefully levelled, especially in the position with the telescope pointing towards the sun. To eliminate instrumental errors the observations should be repeated with vernier set at intervals equidistant along the arc, and A.M. and P.M. observations should be taken at about equal altitudes.

At sea true bearings are obtained by measuring with a sextant the angle between the sun and some distant well-defined object making an angle of from 100° to 120° and observing the altitude of the sun at the same time, together with that of the terrestrial object. The sun's altitude should be low to get the best results, and both limbs should be observed. The sun's true bearing is calculated from its altitude, the latitude and its declination; the horizontal angle is applied to obtain the true bearing of the zero. On shore the theodolite gives the horizontal angle direct, but with sextant observations it must be deduced from the angular distance and the elevation.

Abraham, *Surveying Instruments*, London. (J. A. Ed.)

CHARTER, a written instrument, contract, or convention by which grants of property or of rights and privileges are confirmed and held. The use of the word for any written document is obsolete in England, but is preserved in France, *e.g.*, the École des Chartes at Paris. In feudal times charters of privileges were granted, not only by the Crown, but by mesne lords both lay and ecclesiastical, as well to communities, such as boroughs, gilds and religious foundations, as to individuals. In modern usage grants by charter have become all but obsolete, though in England this form is still used in the incorporation by the Crown of certain public bodies (*see* CHARTERED COMPANIES).

The grant of the Great Charter by King John in 1215 (*see* MAGNA CARTA), which guaranteed the preservation of English liberties, led to a special association of the word with constitutional privileges, and so in modern times it has been applied to constitutions granted by sovereigns to their subjects, in contradistinction to those based on "the will of the people." Such was

the Charter (*Charte*) granted by Louis XVIII. to France in 1814. In Portugal the constitution granted by Dom Pedro in 1826 was called by the French party the "Charter," while that devised by the Cortes in 1821 was known as the "Constitution." Magna Carta also suggested to the English radicals in 1838 the name "People's Charter," which they gave to their published programme of reforms (*see* CHARTISM). This association of the idea of liberty with the word charter led to its figurative use in the sense of freedom or licence. The common colloquialism "to charter," in the sense of to take, or hire, is derived from the special use of "to charter" as to hire (a ship) by charter-party.

CHARTERED ACCOUNTANT: *see* ACCOUNTANCY AND ACCOUNTANTS.

CHARTERED COMPANIES. A chartered company is a corporation enjoying certain rights and privileges, and bound by certain obligations under a special charter granted to it by the sovereign authority of the State, such charter defining and limiting those rights, privileges and obligations, and the localities in which they are to be exercised. Such companies existed in early times, but have undergone changes and modifications in accordance with the developments which have taken place in the economic history of the States where they have existed. In Great Britain the first charters for foreign trade were granted, not to English companies but to branches of the Hanseatic League (*q.v.*), and it was not till 1598 that England was finally relieved from the presence of a foreign chartered company. In that year Queen Elizabeth closed the steel-yard where Teutons had been established for 700 years.

Of all early English chartered companies, the "Merchant Adventurers" conducted its operations the most widely. Itself a development of very early trading gilds, at the height of its prosperity it employed as many as 50,000 persons in the Netherlands. In the reign of Elizabeth British trade with the Netherlands, reached, in one year, 12,000,000 ducats, and in that of James I. the company's yearly commerce with Germany and the Netherlands was as much as £1,000,000. Hamburg afterwards was its principal depot, and it became known as the "Hamburg company." Here it maintained itself until as late as 1808, when the company was at last dissolved. In the "Merchant Adventurers'" enterprises is to be seen the germ of the trading companies which had so remarkable a development in the 16th and 17th centuries. These old regulated trade gilds passed gradually into joint-stock associations, which were capable of far greater extension in both the number of members and the amount of stock, each member being only accountable for the amount of his own stock, and being able to transfer it at will to any other person.

The discovery of the New World, and the opening out of fresh trading routes to the Indies, gave an extraordinary impulse to shipping, commerce and industrial enterprise throughout western Europe. The English, French and Dutch Governments were ready to assist trade by the granting of charters to trading associations. The Baltic trade had already been the sphere of activities of an English company, since Henry IV. founded one by charter in 1404; and Elizabeth revived this "Eastland company" in 1579. To the "Russia company," which received its first charter in 1553, Great Britain owed its first intercourse with Russia and a direct trade with the Levant and Persia. Later, the Turkey company was founded, which in 1592, after amalgamation with the Venice company, took the name of the Levant company. Like the Muscovy company it was still trading in the 18th century. Both the Russia and Turkey companies had an important effect upon British relations with those empires. They maintained British influence in those countries, and even paid the expenses of the embassies which were sent out by the English Government to their courts.

The chartered companies which were formed during this period for trade with the Indies and the New World have had a more wide-reaching influence in history. The East India company (*q.v.*) is dealt with elsewhere. Charters were given to companies trading to Guiana and the Canaries, but none of these enjoyed a very long or prosperous existence, principally owing to the difficulties caused by foreign competition. It is when we turn to North America that the importance of the chartered company, as a colonizing rather than a trading agency, is seen in its full development. The "Hudson's Bay company," which still exists as a commercial concern, is dealt with under its own heading, but many of the 13 British North American colonies were in their inception chartered companies very much in the modern acceptation of the term. The history of these companies will be found under the heading of the different colonies of which they were the origin. It is necessary, however, to bear in mind that two classes of charters are to be found in force among the early American colonies: (1) Those granted to private individuals or to trading associations, which were often useful when the colony was first founded, but which were later withdrawn when the country had become settled and was looking forward to commercial expansion. The colonies were then brought under the direct control of the Crown, and their trade subject only to regulation by the Government. Thus the Virginia company lost their charter in 1624. The substitution of royal and later of parliamentary control for that of the company was an important factor in the growth of the Navigation Acts. (2) The second class of charters were those granted to the settlers themselves as a guarantee of their system of government. This, for example, was the effect of the charter granted to Massachusetts. In the later 17th century, however, the cancellation or amendment of the charters, and the growth of legislative assemblies tended to produce a uniformity of colonial practice, irrespective of the original character of the colony.

Chartered companies continued to be formed for the development of new trade, *e.g.*, the Royal African company in 1662 and the South Sea company in 1711.

In France and Holland, no less than in England, the institution of chartered companies became a settled principle of the Governments of those countries during the whole of the period in question. In France from 1599 to 1789, more than 70 of such companies came into existence, but after 1770, when the great *Compagnie des Indes orientales* went into liquidation, they were almost abandoned, and finally perished in the general sweeping away of privileges which followed on the outbreak of the Revolution. The monopoly rights granted to such companies were in accordance with the views generally accepted at the time, although there were many critics even in the 17th century. There were serious difficulties in the way of private trade owing to the large capital required to maintain factories and the necessity for their supervision. It was only the need for capital which induced statesmen like Colbert to countenance them, and Montesquieu took the same view (*Esprit des lois*, t. xx.c. 10). John de Witt's view was that such companies were not useful for colonization properly so called, because they wanted quick returns to pay their dividends. So, even in France and Holland, opinion was by no means settled as to their utility. In England historic protests were made against such monopolies, but the chartered companies were less exclusive in England than in either France or Holland. French commercial companies were more privileged, exclusive and artificial than those in Holland and England. Those of Holland may be said to have been national enterprises. French companies were more fettered than their rivals by the royal power and had less initiative of their own, and therefore had less chance of surviving.

During the last 20 years of the 19th century there was a great revival of the system of chartered companies in Great Britain. It was a feature of the general growth of interest in colonial expansion and commercial development which had made itself felt almost universally among European nations. But the modern companies were not like those of the 16th and 17th centuries; they were not monopolists, and were more definitely subject to the control of the Home Government. The charters, in fact, prohibited any monopoly of trade, and prescribed a State control which is their distinguishing feature. It is to be exercised in almost all directions in which the companies may come into contact with matters political; it is inevitable in all disputes of the companies with foreign Powers and is extended over all decrees of the company regarding the administration of its territories, the treatment of natives and mining regulations. In all

cases of dispute between the companies and the natives the secretary of State is *ex officio* the judge, and to the secretary of State (in the case of the British South Africa company) the accounts of administration had to be submitted for approbation. The British character of the company is insisted upon in each case in the charter which calls it into life. The Crown always retains complete control over the company by reserving to itself the power of revoking the charter in case of the neglect of the stipulations. Special clauses were inserted in the charters of the British East Africa and South Africa companies enabling the Government to forfeit their charters if they did not promote the objects alleged as reasons for demanding a charter.

The chartered company of these days is therefore very strongly fixed within limits imposed by law on its political action. As a whole, however, very remarkable results have been achieved. This may be attributed in no small degree to the personality of the men who have had the supreme direction at home and abroad, and who have, by their social position and personal qualities, acquired the confidence of the public. With the exception of the Royal Niger company, it would be incorrect to say that they have been financially successful, but in the domain of Government generally it may be said that they have added vast territories to the British empire (in Africa about 1,700,000 sq.m.), and in these territories they have acted as a civilizing force. They have made roads, opened facilities for trade, enforced peace and laid, at all events, the foundation of settled administration; while anti-slavery and anti-alcohol campaigns have been carried on, the latter certainly being against the immediate pecuniary interests of the companies themselves. The occupation of Uganda certainly, and of the Nigerian territory and Rhodesia probably, will prove to have been rather for the benefit of posterity than of the companies which effected it. In the two cases where the companies have been bought out by the State, they have had no compensation for much that they have expended.

One common characteristic is to be noted in the histories of the old chartered companies and the new. In both periods the company has been used by the English Government as a useful instrument of colonial expansion, but in both periods only for temporary uses. When the colony is settled, or Government established, the State takes the lead. This is well illustrated by the history of the slow decline of the independence of the East India company in the 18th century and of the British South Africa company in the 20th. Both these companies are distinguished for their length of days, but both had to submit to the gradual penetration of State control.

See also BORNEO, NIGERIA, RHODESIA, etc. For the share of the chartered company in the development of the modern trading company, *see* COMPANY.

CHARTERHOUSE, a corruption of the French *maison chartreuse*, a religious house of the Carthusians (*q.v.*). The name is found in various places in England (*e.g.*, Charterhouse-on-Mendip, Charterhouse Hinton) where the Carthusians were established, but is most familiarly applied to the Charterhouse, London. Near the old city wall, west of the modern thoroughfare of Aldersgate, a Carthusian monastery was founded in 1371 by Sir Walter de Manny. After its dissolution in 1535, the property was occupied for a time by Queen Elizabeth (in 1558) and by James I. In May 1611 the Charterhouse came into the hands of Thomas Sutton (1532–1611) of Snaith, Lincolnshire, who later settled in London. In 1611, the year of his death, he endowed a hospital on the site of the Charterhouse, calling it the hospital of King James and in his will he bequeathed money to maintain a chapel, hospital (almshouse) and school. The will was hotly contested but upheld in court, and the foundation was finally constituted to afford a home for 80 male pensioners and to educate 40 boys.

The school developed, and now ranks as a public school. In 1872 it was removed to new buildings near Godalming in Surrey. The pensioners still occupy the picturesque buildings of mellowed red brick, which include a panelled chapel, in which is the founder's tomb, the fine dining hall—rebuilt by the monks about 1520—the old library and the great staircase. Many of the buildings were ruined in World War II. Of the hall, the chimney piece and some woodwork survive. The master's house and adjacent buildings were burned out, but the chapel was unharmed. The hall (1872) of Merchant Taylors' school was also burned out.

CHARTER-PARTY: *see* AFFREIGHTMENT.

CHARTIER, ALAIN (*c.* 1392–*c.* 1430), French poet and political writer, was born at Bayeux about 1392. His eldest brother, Guillaume, became bishop of Paris; and Thomas became notary to the king. Jean Chartier, a monk of St. Denis, whose history of Charles VII. is printed in vol. iii. of *Les Grands Chroniques de Saint-Denis* (1477), was not, as is sometimes stated, also a brother of the poet. Alain studied, as his elder brother had done, at the University of Paris. His earliest poem is the *Livre des quatre dames*, written after the battle of Agincourt. This was followed by the *Débat du réveille-matin*, *La Belle Dame sans merci* and others. He was attached to the dauphin, afterwards Charles VII., acting in the triple capacity of clerk, notary and financial secretary. In 1422 he wrote the famous *Quadrilogue-invectif*. The interlocutors in this dialogue are France herself and the three orders of the State. Chartier lays bare the abuses of the feudal army and the sufferings of the peasants. He rendered an immense service to his country by maintaining that the cause of France, though desperate to all appearance, was not yet lost if the contending factions could lay aside their differences in the face of the common enemy. In 1424 Chartier was sent on an embassy to Germany, and three years later he accompanied to Scotland the mission sent to negotiate the marriage of Margaret of Scotland, then not four years old, with the dauphin, afterwards Louis XI. In 1429 he wrote the *Livre d'espérance*, which contains a fierce attack on the nobility and clergy. He was the author of a diatribe on the courtiers of Charles VII., entitled *Le Curial*, translated into English (*Here followeth the copy of a lettre whyche maistre A. Charetier wrote to his brother*) by Caxton about 1484. The story of the famous kiss bestowed by Margaret of Scotland on *la précieuse bouche de laquelle sont issus et sortis tant de bons mots et vertueuses paroles* is mythical, for Margaret did not come to France till 1436, after the poet's death. Jean de Masles, who annotated a portion of his verse, has recorded how the pages and young gentlemen of that epoch were required daily to learn by heart passages of his *Bréviaire des nobles*. John Lydgate studied him affectionately. *La Belle Dame sans merci* was translated into English by Sir Richard Ros about 1640, with an introduction of his own; and Clément Marot and Octavien de Saint-Gelais, writing 50 years after his death, find many fair words for the old poet, their master and predecessor.

See Mancel, *Alain Chartier, étude bibliographique et littéraire*, 8vo (1849); D. Delaunay's *Étude sur Alain Chartier* (1876), with considerable extracts from his writings, and G. Joret-Desclosières, *Alain Chartier* (4th ed., 1899). His works were edited by A. Duchesne (Paris, 1617).

CHARTISM, the name of a revolutionary democratic agitation in Great Britain which came into prominence in 1838 and disappeared after 1850.

The "People's Charter" was the name given to a bill containing the famous six points—equal electoral areas, universal suffrage, payment of members, no property qualifications, vote by ballot, and annual parliaments—all but the last of which have since been secured. These points, which from 1768 had been, partially at

least, the common property of all radical agitation, were first collected into one petition on Feb. 18 1837, by the London Workingmen's Association, founded by William Lovett, as a result of the great disappointment of the Reform Bill of 1832, which enfranchised only the middle class. These six points were drafted into a bill known as the Charter by Lovett, with possibly some assistance from Francis Place, which was published on May 8 1838; and the formal constitution of the Chartist movement is commonly dated from a great meeting held on Aug. 8 on Newhall Hill at which the Charter was approved.

The ultimate aims of the movement were economic—"social equality" or, in the phrase of G. J. Harney's *London Democrat*, (April 27 1839) "that all shall have a good house to live in with a garden back or front, just as the occupier likes; good clothing to keep him warm and to make him look respectable, and plenty of good food and drink to make him look and *feel* happy." The Chartists were not unanimous about the means of securing this social equality, but a provisional agreement on universal suffrage as the necessary first step provided the basis of the movement. The London Workingmen's Association, which launched the campaign by sending out "missionaries" all over Great Britain, consisted of skilled workers mostly above the poverty line: not so the supporters to whom they appealed. The factory workers, colliers and handloom workers of the North and Midlands, who became the chief adherents of Chartism, were passing through a period of extreme misery and degradation, which was not at this time mitigated by any effectively administered Factory Act (except one which limited, in some cases, the working hours of certain children to 12). Two Tory factory reformers, Richard Oastler and the Rev. J. R. Stephens, were, moreover, conducting, in an exceedingly violent manner, a campaign against the provisions of the Poor Law of 1834, which aimed at making poor relief more unpleasant than the most unpleasant means of gaining a livelihood outside. Oastler and Stephens, whose campaign in several areas succeeded in postponing its application, threw their weight into the Chartist movement, and over the whole of the Northern area torchlight meetings were held at night on the moors, in which armed insurrection was freely advocated. Scotland, and the west of England, which was evangelized by Henry Vincent, the most eloquent Chartist orator, were the moderate areas: the Welsh miners were the most revolutionary. Feargus O'Connor (*q.v.*), an Irish squire who had formerly (1832–35) been one of O'Connell's "tail" in Parliament, became rapidly the most popular leader, and rarely made a speech without alluding to physical force.

The new Chartist plan of campaign was, however, provided by a banker, Thos. Attwood, M.P. for Birmingham, who trusted that a Charter parliament would adopt his views on currency. He proposed the election, by the disfranchised, of an anti-Parliament to be called the Convention which would sit as a rival to the House of Commons and present a petition, signed by the mass of the working class, for the enactment of the Charter as the law of the land. If the Commons refused, the Convention would then call a general strike (the "Sacred Month"). This exhilarating programme was enthusiastically taken up; the petition was signed by 1,280,000 people and the members of the Convention, elected by public meetings, held their first sitting in London on Feb. 4 1839. The Convention was at the beginning controlled by the "moral force men" headed by Lovett, but it was not able to prevent frequent violent conflicts with the police (in which the Chartists were not uncommonly victorious) and the moderates entirely lost control when on July 12 the Commons, after long delays, rejected the petition. Post-dated orders for the General Strike were forthwith issued, amid great excitement. Only a few days had passed, however, when the Convention realized that it had behind it no organization and no preparations, and in consequence somewhat ignominiously cancelled the orders on July 22.

What the "moral force men" would not do, others were prepared to attempt. During the Convention a secret military organization had been formed, directed by a committee of five: its plans were completed at a private conference held in the autumn at Heckmondwike. The signal for the insurrection was to be given by the capture of Newport (Mon.) and the release of Vincent from Monmouth Castle. The other centres of revolt appear to have been in Lancashire and Yorkshire. The attack on Newport was led by the ex-mayor and J.P., John Frost, on the morning of Nov. 4. It was to have been in three columns, but owing to mismanagement the columns failed to unite at Risca and Frost attacked alone with about 3,000 men armed with rifles and mandrils (collier's picks). Warning had been given and the Chartists walked into a trap in the square outside the Westgate hotel. They were defeated after a very brief struggle, leaving a considerable number (the figures are disputed) of killed and wounded. The leaders, Frost, Jones and Williams, were sentenced to death, afterwards mitigated to transportation. The police also rounded up nearly every other Chartist leader of importance, and secured sentences of one or two years' imprisonment.

On the release of the leaders in 1840 and 1841 renewed quarrels broke out between the "physical force men" led by O'Connor and his assistant on the *Northern Star*, G. J. Harney, and the "moral force men" led by Lovett and Bronterre O'Brien. The latter considered that the working class had not sufficient strength to achieve reform alone and should now invite the aid of sympathetic middle-class groupings: O'Connor and his allies declared that the middle-class reformers, responsible for the deception of 1832, were also the worst oppressors of the operatives in the factories and mines. O'Connor, with the assistance of his journal the *Star*, which secured a hitherto unparalleled circulation, carried the day and drove the other section out of the movement. His popularity became enormous, due to his hard work, his hatred of the middle class and his remarkable invective, of which the following is a specimen: "You—I was just coming to you when I was describing the materials of which our spurious aristocracy is composed. You, gentlemen, belong to the big-bellied, little-brained, numskull aristocracy. How dare you hiss me, you contemptible set of platterfaced, amphibious politicians?" A national organization, technically illegal, called the National Charter Association, was founded, which gave some coherence to the movement. It secured the allegiance of a number of trade union branches and promoted a second petition which received the startling number of 3,315,752 signatures. The year 1842, when this was presented, marks the high water-mark of Chartism. After its rejection on May 2, the Chartist executive turned an existing small strike at Ashton into a general strike for the Charter (Aug. 12). They brought out Lancashire, Cheshire, the Potteries and several other industrial districts; the strikers marching from town to town knocking the plugs out of the boilers where resistance was offered (hence the name Plug Riots). Owing to inadequate communications, the strike spread slowly, but trades as far north as Aberdeen had decided to come out, when, his nerve failing, O'Connor suddenly declared the strike was a plot of the Anti-Corn Law League. This action broke up the strike which ended almost at once in defeat. Thereafter Chartism entered into a period of decline, in which interest was chiefly directed to a financially unsound scheme for settling Chartists on the land as smallholders, by means of a National Land Company directed by O'Connor. One settlement only (O'Connorville, 1847, Herringsgate, Bucks) was opened. Enthusiasm was revived in 1847 by the election of O'Connor as M.P. for Nottingham, and in 1848 by the sensational series of revolutions on the continent. Fired by the hope of similar victories, O'Connor promoted a petition, which he said had 6,000,000 signatures, and arranged for the calling of a "National Assembly." The petition was to be presented by a procession of Chartists marching from Kennington Common to the House of Commons on April 10 1848. Believing this to be the day fixed for the revolution, the Government garrisoned London so heavily that the procession was abandoned. The petition, further, was announced by the Government to contain under 2,000,000 signatures, and it was also discovered that the Land Company was bankrupt. Under the influence of this series of fiascos, O'Connor became distracted in his mind: his successor, Ernest Jones, endeavoured in vain to revive the legal movement which by about 1854 may be regarded as extinct. The illegal revolutionary organization prepared an insurrection for Whit-Monday 1848, later adjourned to Aug. 15, but as it was carefully

watched and, indeed, partly directed by police informers, its effort was suppressed without difficulty.

The disappearance of Chartism was due not so much to the folly of its leaders as to the increasing comfort of the working class in the period of prosperity following on the Corn Law Repeal (1846), and the enforcement of the factory reforms secured by Lord Shaftesbury (*q.v.*). Working-class interest henceforward was diverted to the co-operative movement and the new craft trade unions, of which the most famous, the Amalgamated Society of Engineers, was founded in 1851.

BIBLIOGRAPHY.—There are two *Histories of the Chartist Movement*, both unfinished, by Mark Hovell (1917) and Julius West (1920). *See* also M. Beer, *History of British Socialism* 2 vols. (1919, 1920). For original authorities *see* R. W. Postgate, *Revolution from 1789 to 1906* (1920); R. G. Gammage, *History of Chartism* (1854); W. Mus., Add mss. 27,819–21), and the file of the *Northern Star*. (R. W. P.)

CHARTRES, a city of north-western France, capital of the department of Eure-et-Loir, 55 m. south-west of Paris on the railway to Le Mans. Pop. (1936) 26,747. Chartres is on the left bank of the Eure, on a hill crowned by its famous cathedral, the spires of which are a landmark on the plain of Beauce, "the granary of France." The Eure, which divides into three branches, is crossed by several bridges, some ancient, and is fringed by remains of fortifications, notably the Porte Guillaume (14th century) flanked by towers. The steep, narrow streets of the old town contrast with the boulevards which encircle it and divide it from the suburbs. The cathedral of Notre-Dame (*see* ARCHITECTURE: *Gothic Architecture;* STAINED GLASS; SCULPTURE), was founded by Bishop Fulbert (11th century) on the site of a church which had been destroyed by fire. In 1194 another fire made new building necessary and the present church was finished by 1240; there have been minor additions and alterations since that time. A fire in 1836 destroyed the upper woodwork. The statuary of the portals, the stained glass of the 13th century, and the choir-screen of the Renaissance are all unique. The south spire, the Clocher Vieux (351 ft. high), dates from the 12th century; the Clocher Neuf (377 ft.) was not completed till the 16th century. The cathedral is 440 ft. long, its choir measures 150 ft. across, and the vaulting is 121 ft. high. The abbey church of St. Pierre, chiefly 13th century, contains fine stained glass and twelve representations of the apostles in enamel (1547) by Léonard Limosin. St. Martin-au-Val is a 12th century church. The hôtel de ville (17th century) contains a museum and library, an older hôtel de ville is of the 13th century, and there are mediaeval and Renaissance houses.

Chartres was one of the principal towns of the Carnutes, and by the Romans was called *Autricum,* from the river *Autura* (Eure), and afterwards *civitas Carnutum.* It was burnt by the Normans in 858, and unsuccessfully besieged by them in 911. It was in English hands 1417–32. It was attacked unsuccessfully by the Protestants in 1568, and was taken in 1591 by Henry IV., who was crowned there three years afterwards. It was seized by the Germans on Oct. 21, 1870, and used as a centre of operations. During the middle ages it gave its name to a countship held by the counts of Blois and Champagne and afterwards by the house of Châtillon, a member of which in 1286 sold it to the crown. It was raised to the rank of a duchy in 1528 by Francis I.

The town is the seat of a bishop, a prefecture, a court of assizes, and has tribunals of first instance and of commerce and a chamber of commerce. It is a market-town for Beauce. Game-pies of Chartres are well known, and industries include flour milling, timber sawing, brewing, distilling, iron founding, leather manufacture, dyeing, and the manufacture of stained glass, billiard requisites, hosiery, machinery, etc.

CHARTREUSE. A celebrated liqueur, green and yellow, with a distinctive flavouring of angelica root. It is made at La Grande Chartreuse, the old Carthusian monastery near Grenoble. The Carthusian order of monks was founded by Saint Bruno of Cologne in 1084. In 1607 the Maréchal d'Estrées gave to the Carthusian Fathers the recipe of the elixir. It was supposed to be concocted from a distillation of herbs, culled on the slopes of the Dauphiné valley, and the finest brandy. In 1757 Brother Gérôme Maubec, "a very clever apothecary," perfected the formula, the secret of which, however, was never divulged nor discovered by analysis. Although in the Revolution of 1793 the Carthusians were despoiled of their property, they retained the secrets of their formula. In 1816 they were allowed to return to their monastery, but in 1901 were in trouble again owing to the decree for the expulsion of the religious orders from France. They locked themselves in their monastery, but were eventually expelled and their distillery at Fourvoire was sold, including their trade-mark. The monks emigrated to Farneta, near Lucca, in Italy, and later acquired a distillery at Tarragona in Spain, taking their famous recipe with them. Meantime, the new French owners of the monastery near Grenoble began to sell an imitation liqueur under the original trade-mark. Thereupon the monks adopted *Les Pères Chartreux* as their new trade-mark and registered it in many countries. In London, the high court of justice decided that the French "Chartreuse" could not lawfully be sold in the United Kingdom as being the monks' product. This decision was qualified by the fact that certain stocks of the original liqueur remained in existence and it was ruled that these might be sold lawfully. If bottles are merely labelled "Chartreuse" it is certain that the liqueur was made by the monks before their expulsion from France. The only guarantee of their origin is the printer's name, Alier, on the label, but stocks bearing this label were virtually exhausted by 1944. In 1938 the Carthusian monks were allowed to return to their property at Grenoble and the distillation of the liqueur was being revived there. (J. V. M.; F. W. D.)

CHARTREUSE, LA GRANDE, the mother house of the order of Carthusian monks (*see* CARTHUSIANS). It is situated in the French department of the Isère, about 12½ m. N. of Grenoble, at a height of 3,205 ft. above the sea, in the heart of a group of limestone mountains, and not far from the source of the Guiers Mort. The original settlement here was founded by St. Bruno in 1084, and derived its name from the small village to the southeast, formerly known as Cartusia, and now as St. Pierre de Chartreuse. The first convent on the present site was built between 1132 and 1137, but the actual buildings date only from about 1676, the older ones often having been burned. One of the most famous of the early Carthusian monks was St. Hugh of Lincoln, who lived here from 1160 to 1181, when he went to England as prior of the first Carthusian house at Witham, Somerset; in 1181 he became bishop of Lincoln, and before his death in 1200 had built the angel choir and other portions of the cathedral there.

The monks were expelled in 1792, but were allowed to return in 1816, when they had to pay rent for the use of the buildings and the forests around. They were again expelled in 1903, and were dispersed in various houses in England, at Pinerolo (Italy) and at Tarragona (Spain). The high roofs of dark slate, the cross-surmounted turrets and the lofty clock-tower are the chief features of the buildings of the convent, which are not very striking. Women were formerly lodged in the old infirmary, close to the main gate, which is now a hotel. Within the conventual buildings are four halls formerly used for the reception of the priors of various branch houses in France, Italy, Burgundy and Germany. The very plain and unadorned chapel dates from the 15th century, but the cloisters, around which cluster the 36 small houses for the fully professed monks, are of later date. The library contained before the Revolution a very fine collection of books and mss., most of them now in the town library at Grenoble.

CHARWOMAN. A word of interesting origin, meaning one who is hired to do occasional household work. "Char" or "chare," which forms the first part of the word, is common, in many forms, to Teutonic languages, meaning a "turn," and, in this original sense, is seen in "ajar," properly "on char," of a door "on the turn" in the act of closing. It is thus applied to a "turn of work," an odd

job, and is so used, in the form "chore," in the United States, and in dialects of the south-west of England.

CHASE, SALMON PORTLAND (1808–1873), American statesman and jurist, was born in Cornish, N.H., on Jan. 13, 1808. His father died in 1817, and the son passed several years (1820–24) in Ohio with his uncle, Bishop Philander Chase (1775–1852), the foremost pioneer of the Protestant Episcopal Church in the West. He graduated at Dartmouth college in 1826, and after studying law under William Wirt, attorney-general of the United States, in Washington, D.C., was admitted to the bar in 1829, and removed to Cincinnati, O., in 1830. Here he soon gained a position of prominence at the bar.

At a time when public opinion in Cincinnati was largely dominated by Southern business connections, Chase, influenced probably by James G. Birney, associated himself after about 1836 with the anti-slavery movement, and became recognized as the leader of the political reformers as opposed to the Garrisonian abolitionists. To the cause he freely gave his services as a lawyer, and was particularly conspicuous as counsel for fugitive slaves seized in Ohio for rendition to slavery under the Fugitive Slave law of 1793 —indeed, he came to be known as the "attorney-general of fugitive slaves." His argument (1847) in the famous Van Zandt case before the United States Supreme Court attracted particular attention though in this as in other cases of the kind the judgment was against him. In brief he contended that slavery was "local, not national," that it could exist only by virtue of positive State law, that the Federal Government was not empowered by the Constitution to create slavery anywhere, and that "when a slave leaves the jurisdiction of a State he ceases to be a slave, because he continues to be a man and leaves behind him the law which made him a slave."

In 1841 he abandoned the Whig Party, with which he had previously been affiliated, and for seven years was the undisputed leader of the Liberty Party in Ohio; he was remarkably skilful in drafting platforms and addresses, and it was he who prepared the national Liberty platform of 1843 and the Liberty address of 1845. Realizing in time that a third-party movement could not succeed, he took the lead during the campaign of 1848 in combining the Liberty Party with the Barnburners or Van Buren Democrats of New York to form the Free-Soilers. He drafted the famous Free-Soil platform, and it was largely through his influence that Van Buren was nominated for the presidency. His object, however, was not to establish a permanent new party organization, but to bring pressure to bear upon Northern Democrats to force them to adopt a policy opposed to the further extension of slavery.

In 1849 he was elected to the United States Senate as the result of a coalition between the Democrats and a small group of Free-Soilers in the State legislature; and for some years thereafter, except in 1852, when he rejoined the Free-Soilers, he classed himself as an Independent Democrat, though he was out of harmony with the leaders of the Democratic Party. During his service in the Senate (1849–55) he was pre-eminently the champion of anti-slavery in that body, and no one spoke more ably than he did against the Compromise Measures of 1850 and the Kansas-Nebraska bill of 1854. The Kansas-Nebraska legislation, and the subsequent troubles in Kansas, having convinced him of the futility of trying to influence the Democrats, he assumed the leadership in the North-west of the movement to form a new party to oppose the extension of slavery. The "Appeal of the Independent Democrats in Congress to the People of the United States," written by Chase and Giddings, and published in the New York *Times* of Jan. 24, 1854, may be regarded as the earliest draft of the Republican Party creed. He was the first Republican governor of Ohio, serving from 1855 to 1859.

Although, with the exception of Seward, he was the most prominent Republican in the country, and had done more against slavery than any other Republican, he failed to secure the nomination for the presidency in 1860, partly because his views on the question of protection were not orthodox from a Republican point of view, and partly because the old line Whig element could not forgive his coalition with the Democrats in the senatorial campaign of 1849; his uncompromising and conspicuous anti-slavery record, too, was against him from the point of view of "availability." As secretary of the Treasury in President Lincoln's cabinet in 1861–64, during the first three years of the Civil War, he rendered services of the greatest value. That period of crisis witnessed two great changes in American financial policy, the establishment of a national banking system and the issue of a legal tender paper currency. The former was Chase's own particular measure. He suggested the idea, worked out all of the important principles and many of the details, and induced Congress to accept them. The success of that system alone warrants his being placed in the first rank of American financiers. It not only secured an immediate market for Government bonds, but it also provided a stable uniform national currency.

Perhaps Chase's chief defect as a statesman was an insatiable desire for supreme office. It was partly this ambition, and also temperamental differences from the president, which led him to retire from the cabinet in June 1864. A few months later (Dec. 6, 1864) he was appointed chief justice of the United States Supreme Court to succeed Judge Taney, a position which he held until his death. Toward the end of his life he gradually drifted back toward his old Democratic position, and made an unsuccessful effort to secure the nomination of the Democratic Party for the presidency in 1872. He died in New York city on May 7, 1873. Chase was one of the ablest political leaders of the Civil War period, and deserves to be placed in the front rank of American statesmen.

The standard biography is A. B. Hart's *Salmon Portland Chase* in the "American Statesmen Series" (1899). Less philosophical, but containing a greater wealth of detail, is J. W. Shuckers' *Life and Public Services of Salmon Portland Chase* (1874). R. B. Warden's *Account of the Private Life and Public Services of Salmon Portland Chase* (Cincinnati, 1874) deals more fully with Chase's private life. *See* also Floyd Pershing Gates, *Salmon P. Chase and the Independent Democrats* (1918); and Arthur M. Schlesinger, *Salmon Portland Chase, Undergraduate and Pedagogue* (1919).

CHASE, SAMUEL (1741–1811), American jurist, was born in Somerset county (Md.), April 17, 1741. He was admitted to the bar at Annapolis in 1761, and for more than 20 years was a member of the Maryland legislature. He took an active part in the resistance to the Stamp Act, and from 1774 to 1778 and 1784 to 1785 was a member of the Continental Congress. He did much to persuade Maryland to advocate a formal separation of the 13 colonies from Great Britain, and signed the Declaration of Independence on Aug. 2, 1776. In 1791 he became chief judge of the Maryland general court, but resigned in 1796 to become associate justice of the U.S. Supreme Court. Because of his activities on behalf of the Federalist party, the House of Representatives adopted a resolution of impeachment in March, 1804, and on Dec. 7, 1804, the House managers, chief among whom were John Randolph, Joseph H. Nicholson (1770–1817), and Caesar A. Rodney (1772–1824), laid their articles of impeachment before the Senate. The trial, which lasted from Jan. 2 to March 1, 1805, ensued on an indictment of eight articles, dealing with his conduct in the Fries and Callender trials, with his treatment of a Delaware grand jury, and (in article viii.) with his making "highly indecent, extrajudicial" reflections upon the national administration. On only three articles was there a majority against Judge Chase, the largest, on article viii., being four short of the necessary two-thirds to convict.

"The case," says Henry Adams, "proved impeachment to be an impracticable thing for partisan purposes, and it decided the permanence of those lines of constitutional development which were a reflection of the common law." Judge Chase resumed his seat on the bench, and occupied it until his death, June 19, 1811.

See *The Trial of Samuel Chase* (2 vols., Washington, 1805), reported by Samuel H. Smith and Thomas Lloyd; an article in *The American Law Review*, vol. xxxiii. (St. Louis, 1899); and Henry Adams's *History of the United States*, vol. ii. (1889). *See* also J. H. Hazelton, *The Declaration of Independence* (1906); and *The Maryland Signers of the Declaration of Independence* (Baltimore, 1912).

CHASE, WILLIAM MERRITT (1849–1916), American painter, was born at Franklin, Ind., on Nov. 1, 1849. He was a pupil of B. F. Hays in Indianapolis, of J. O. Eaton in New York and of A. Wagner and Piloty in Munich. In New York he established a school of his own, after having taught with success for

some years at the Art Students' League. A worker in all mediums —oils, water-colour, pastel and etching—painting with distinction the figure, landscape and still life, he is perhaps best known by his portraits, his sitters numbering some of the most important men and women of his time.

Chase won many honours at home and abroad, became a member of the National Academy of Design, New York, and for ten years was president of the Society of American Artists. In 1912 he was awarded the Proctor Prize by the National Academy of Design for his "Portrait of Mrs. H." At the Panama Pacific Exposition (1915) a special room was assigned to his works. Among his most important canvases are "Ready for the Ride" (Union League Club, N.Y.), "The Apprentice," "Court Jester," and portraits of the painters, Whistler and Duveneck; of General Webb and of Peter Cooper.

See J. Walker McSpadden, *Famous Painters of America* (1916).

CHASE. (1) The pursuit of wild animals for food or sport (Fr. *chasse*, Lat. *capere*, to take), and so the pursuit of anything. (*See* HUNTING.) The word was also applied to park land reserved for the breeding and hunting of wild animals; *cf.* various place-names in England, as Cannock Chase. It is also a term for a stroke in tennis. (*See* LAWN TENNIS AND TENNIS.) (2) An enclosure (Fr. *châsse*, Lat. *capsa*, a box), such as the muzzle-end of a gun in front of the trunnions, or, in typography (*q.v.*) the frame enclosing the page of type. (*See* PRINTING.)

CHASE NATIONAL BANK, THE, of the city of New York was founded on Sept. 12, 1877. Its first published balance sheet (Dec. 27, 1877) showed total resources of $1,042,009.25. The statement for March 30, 1940, showed total resources of $3,345,528,389.43; common capital stock of $100,270,000.00 and surplus and undivided profits of $136,486,918.24. On the same date, the bank had 35 branches in greater New York, and branches in London, Havana, San Juan, Panama, Colon, Cristobal and Balboa. An affiliate, The Chase Bank (organized under the Edge Act), had branches in Paris, Shanghai, Hongkong and Tientsin. The Chase National Bank occupies a prominent position in the field of both domestic and foreign commercial banking, acts as New York correspondent for thousands of other banks in the United States and abroad, and maintains a large trust department.

Principal executive officers in 1940 were Winthrop W. Aldrich, chairman, board of directors, and H. Donald Campbell, president. Mergers with three other large New York banks and a number of smaller institutions were consummated between 1921 and 1931, as follows:

Nov. 23, 1921, Metropolitan Bank; April 12, 1926, Mechanics & Metals National Bank; Dec. 28, 1927, Mutual Bank; Jan. 26, 1929, Garfield National Bank; Aug. 24, 1929, National Park Bank; June 2, 1930, Equitable Trust Company and Interstate Trust Company; Dec 19. 1931, American Express Bank & Trust Co.

CHASING, the art of producing figures and ornamental patterns, either raised or indented, on metallic surfaces by means of steel tools or punches. (*See* SILVERSMITHS' AND GOLDSMITHS' WORK.) The chaser first outlines the pattern on the surface he is to ornament, after which, if the work requires bold or high embossments, this is blocked out by a process called "snarling." The snarling iron is a long iron tool turned up at the end, and made so that when securely fastened in a vice the upturned end can reach and press against any portion of the interior of the vase or object to be chased. The part to be raised being held firmly against the upturned point of the snarling iron, the workman gives the shoulder or opposite end a sharp blow which raises the surface of the metal held against the tool. When the blocking out from the interior is finished, the object to be chased is filled with molten pitch, which is allowed to harden. It is then fastened to a sandbag, and with hammer and a multitude of small punches of different outline the details of the pattern (lined, smooth or "mat") are worked out. Embossing and stamping from steel dies and rolled ornaments have taken the place of chased ornamentations in the cheaper kinds of plated works. (*See* EMBOSSING.)

CHASLES, MICHEL (1793–1880), French mathematician, was born on Nov. 15, 1793, at Epernon. He was educated at Paris, and engaged in business, which he later gave up for the study of mathematics. Chasles was made professor of geodesy and mechanics at the Polytechnic school and later professor of higher geometry at the Sorbonne. He and Steiner independently elaborated modern projective geometry, but the interchange of scientific ideas was so poor that the former did not know of the work of the latter. Chasles used his "method of characteristics" and his "principle of correspondence" to solve many problems; the solutions were published in a series of papers in *Comptes Rendus*. The problem of the attraction of an ellipsoid on an external point was solved by him in 1846. Many of his original memoirs were later published in the *Journal de l'École Polytechnique*. Chasles wrote two text-books, *Higher Geometry* (1852) and *Conic Sections* (1865). His *Aperçu historique sur l'origine et la développement des méthodes en géometrie* (1837) is a standard work, the subject being continued in *Rapport sur le progrès de la géometrie* (1870). Chasles died in Paris on Dec. 18, 1880.

CHASLES, PHILARÈTE (1798–1873), French critic and man of letters, was born at Mainvilliers (Eure et Loir). His father, P. J. M. Chasles (1754–1826), was a member of the Convention, and brought up his son according to the principles of Rousseau's *Émile*. Philarète, after a régime of outdoor life, followed by some years of classical study, was apprenticed to a printer. He contributed to the *Revue des deux mondes*, until he had a violent quarrel, terminating in a lawsuit, with François Buloz, who won his case. He became librarian of the Bibliothèque Mazarine, and from 1841 was professor of comparative literature at the Collège de France. During his active life he produced some 50 volumes of literary history and criticism and of social history.

Among his best critical works is *Dix-huitième Siècle en Angleterre . . .* (1846), one of a series of 20 vols. of *Études de littérature comparée* (1846–75), which he called later *Trente ans de critique*. An account of his strenuous boyhood is given in his *Maison de mon père*. His *Mémoires* (1876–77) did not fulfil the expectations based on his brilliant talk.

CHASSÉ, a gliding step in dancing, so called since one foot is brought up behind, or chases, the other. The *chassé croisé* is a double variety of the step.

CHASSELOUP-LAUBAT, FRANÇOIS, MARQUIS DE (1754–1833), French general and military engineer, was born at St. Sernin (Lower Charente), and entered the French engineers in 1774. In 1791 he was promoted captain, and his ability was recognized in the campaigns of 1792. After serving as chief engineer at the siege of Mainz (1796), he was sent to Italy, where he conducted the first siege of Mantua, and afterwards to the new Rhine frontier of France. He was chief of engineers in the army of Italy in 1799, and Napoleon's engineer general in 1800; and he was afterwards employed in reconstructing the defences of the famous Quadrilateral in northern Italy (1801–05). His *chef-d'oeuvre* was the great fortress of Alessandria on the Tanaro. Chasseloup served in Napoleon's campaign of 1806–07, directing the sieges of Colberg, Danzig and Stralsund; and again in 1809, in Italy. Soon after his last campaign, in Russia (1812), he retired from active service, and was made a peer of France and a knight of St. Louis by Louis XVIII. He voted in the chamber of peers against the condemnation of Marshal Ney. In politics he belonged to the constitutional party.

As an engineer Chasseloup was an adherent, though of advanced views, of the old bastioned system. His front was applied to Alessandria, as has been stated, and contains many elaborations of the bastion trace, with, in particular, masked flanks in the tenaille, which served as extra flanks of the bastions. The bastion itself was carefully and minutely retrenched. The ordinary ravelin he replaced by a heavy casemated caponier after the example of Montalembert, and, like Bousmard's, his own ravelin was a large and powerful work pushed out beyond the glacis.

Chasseloup's only published works were, *Correspondance d'un général français avec un général autrichien.* (1801; republ. 1803 or 1809 as *Correspondance de deux généraux . . .*) and *Extraits de Mémoires sur quelques parties de l'artillerie et de fortifications* (Milan, 1805; republ. 1811 as *Essais sur quelques parties . . .*). The most important of his papers are in ms. in the Depôt of Fortifications, Paris.

CHASSEPOT, officially "fusil modèle 1866," a military breech-loading rifle, famous as the arm of the French forces in

the Franco-German War of 1870–71. It was called after its inventor, Antoine Alphonse Chassepot (1833–1905), who had previously constructed a series of experimental forms of breech-loader and it became the French service weapon in 1866. In the following year it made its first appearance on the battlefield at Mentana, where it inflicted severe losses upon Garibaldi's troops. In the war of 1870 it proved very greatly superior to the German needle gun. The breech was closed by a bolt very similar to those of more modern rifles, and amongst the technical features of interest were the method of obturation and the retention of the paper cartridge. It was sighted to 1,312 yd. (1,200 metres).

CHASSÉRIAU, THÉODORE (1819–1856), French painter, was born in the Antilles on Sept. 20, 1819, and died in Paris on Oct. 8, 1856. He studied under Ingres at Paris and at Rome, subsequently falling under the influence of Paul Delaroche. In his short life he produced little. There are decorative paintings by him in the church of St. Méry and the Salle des Comptes in the Palais d'Orsay, and some characteristic lithographs imaginative in character and original in execution, which link him with the artists of the '70s and '80s rather than with his contemporaries or predecessors.

CHASSEURS, light infantry or cavalry regiments in the French army (from Fr. *chasser*, to hunt). The first light infantry (*chasseurs à pied*) units were raised in 1743, and by 1794 their number had increased to 21 battalions. The name then disappeared until 1840, but by 1870 they had again increased to their original figure, and by the outbreak of World War I to 30 battalions, of which 12 were known as *Chasseurs Alpins*. They were specially equipped and trained for mountain warfare.

Under the French army organization at mid-20th century these 30 battalions of *chasseurs* were formed as independent units for administrative purposes, but were grouped into demibrigades of three battalions for war. They were distinguished from the infantry by their dark blue uniforms. During the period just prior to World War II a few battalions of *chasseurs* were integrated into armoured divisions as motorized infantry. The French army at the end of the war included a number of battalions of *chasseurs*, of which several were alpine or motorized.

The light cavalry (*chasseurs à cheval*) regiments were first instituted in 1779. They performed notable service in the European campaigns of the Second Empire. At the close of World War I they were represented by five regiments of *Chasseurs d'Afrique* originally recruited for service in Algeria. The peace and war organization of these *Chasseurs d'Afrique* regiments corresponded in principle to that of a line cavalry unit. Between World Wars I and II and during the latter war the number of these regiments increased progressively, and they were transformed into armoured units.

The only unit of mounted *Chasseurs d'Afrique* still in existence in 1939 was a squadron stationed at Senlis, France.

(C. W. He.)

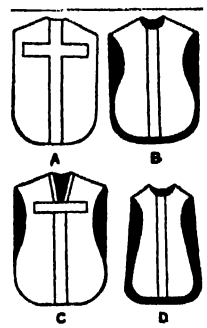
CHASTELARD, PIERRE DE BOCSOZEL DE (1540–1563), French poet, was born in Dauphiné, a scion of the house of Bayard. His name is inseparably connected with Mary, Queen of Scots. From the service of the Constable Montmorency Chastelard then a page passed to the household of Marshal Damville, whom he accompanied on his journey to Scotland in escort of Mary (1561). He returned to Paris in the marshal's train, but left for Scotland again shortly afterwards, bearing letters of recommendation to Mary from his old protector, Montmorency and the *Regent* addressed to the ex-queen of France by Pierre Ronsard, his master in the art of song. He undertook to transmit to the poet the service of plate with which Mary rewarded him. But he had fallen in love with the queen, who is said to have encouraged his passion. The young man hid himself under her bed, where he was discovered by her maids of honour. Mary pardoned the offence but Chastelard was so rash as again to violate her privacy. He was discovered a second time, seized, sentenced and hanged the next morning. He met his fate valiantly and consistently, reading, in his way to the scaffold, his master's noble *Hymne de la mort*, and turning at the instant of doom towards the palace of Holyrood, to address to his unseen mistress the famous farewell—"Adieu, la plus belle et la plus cruelle princesse du monde." This at least is the version of the *Vie des dames illustres* of Brantôme.

CHASTELLAIN, GEORGES (*c.* 1415–1475), Burgundian poet and chronicler, was a native of Alost, in Flanders. He saw active service in the Anglo-French Wars and elsewhere. In 1434 he received a gift from Philip the Good, duke of Burgundy, for his military service. After the peace of Arras (1435) he abandoned soldiering for diplomacy. The next ten years were spent in France, where he was connected with Georges de la Trémoille, and afterwards entered the household of Pierre de Brézé, at that time seneschal of Poitou, by whom he was employed on missions to the duke of Burgundy, in an attempt to establish better relations between Charles VII. and the duke. On the further breach between the two princes, Chastellain left the French service to enter Philip's household, and in 1457 he became a member of the ducal council. He was continually employed on diplomatic errands until 1455, when he was made Burgundian historiographer. He worked at his *Chronique*, with occasional interruptions in his retreat to fulfil missions in France, or to visit the Burgundian court. He was assisted, from about 1463 onwards, by his disciple and continuator, Jean Molinet, whose rhetorical and redundant style may be fairly traced in some passages of the *Chronique*. Chastellain died at Valenciennes on Feb. 13 (according to the treasury accounts), or on March 20 (according to his epitaph), 1475. Only about one-third of the whole *Chronique*, which extended from 1419 to 1474, is extant.

Among his contemporaries Chastellain acquired a reputation by his poems and occasional pieces. He was no mere annalist, but proposed to fuse and shape his vast material to his own conclusions, in accordance with his political experience. The most interesting feature of his work is the skill with which he pictures the leading figures of his time.

The known extant fragments of Chastellain's *Chronique* with his other works were edited by Kervyn de Lettenhove for the Brussels Academy in 1863–66 (Brussels) as *Oeuvres de Georges Chastellain*. This edition includes three volumes of minor pieces of considerable interest, especially *Le Temple de Boccace*, dedicated to Margaret of Anjou, and the *Déprécation* for Pierre Brézé, imprisoned by Louis XI. The attribution to Chastellain is in some cases erroneous, notably in the case of the *Livre des faits de Jacques de Lalaing*, which is probably the work of Lefèbvre de Saint-Remi, herald of the Golden Fleece. In the allegorical *Oultré d'amour* it has been thought a real romance between Brézé and a lady of the royal house is concealed.

See A. Molinier, *Les Sources de l'histoire de France;* notices by Kervyn de Lettenhove prefixed to the *Oeuvres* and in the *Biographie nationale de Belgique;* and Kenneth Urwin, *Georges Chastellain: la vie, les oeuvres* (Paris, 1937).



CHASUBLE, a liturgical vestment of the Catholic Church, being the outermost garment worn by bishops and priests when celebrating the Mass. The word is derived, through the French, from the Latin *casula*, a little house or hut. Since the chasuble (or *planeta*, as it is also called in the Roman Missal) is only used at the Mass, or rarely for functions intimately connected with the sacrament of the altar, it may be regarded as the Mass vestment *par excellence*. According to the prevailing model in the Roman Catholic Church it is a scapular-like cloak, with a hole in the middle for the head, falling down over breast and back, and leaving the arms uncovered at the sides. Its shape and size, however, differ considerably in various countries (*see* fig.), while some churches—*e.g.*, those of certain monastic orders—have retained or reverted to the earlier "Gothic" forms to be described later. According to the decisions of the Congregation of Rites, chasubles must not be of linen, cotton or woollen stuffs, but of silk; though a mixture of wool (or linen and cotton) and silk is allowed if the silk completely cover the other material on the outer side.

The chasuble, like the kindred vestments in the Eastern Churches, is derived from the Roman *paenula* or *planeta*, a cloak worn by all classes and both sexes in the Graeco-Roman world (*see* VESTMENTS).

At the Reformation the chasuble was rejected with the other vestments by the more extreme Protestants. Its use, however,

survived in the Lutheran churches; and though in those of Germany it is no longer worn, it still forms part of the liturgical costume of the Scandinavian Evangelical churches. In the Church of England, though it was prescribed alternatively with the cope in the first prayer-Book of Edward VI., it was ultimately discarded with the other "Mass vestments." (*See* VESTMENTS.)

Form.—The chasuble was originally a tent-like robe which fell in loose folds below the knee of the wearer. Its inconvenience, however, was obvious, and a process of cutting away at the sides began, which continued until the tent-shaped chasuble of the 12th century had developed in the 16th into the present scapular-like vestment. This process was, moreover, hastened by the substitution of costly and elaborately embroidered materials for the simple stuffs of which the vestment had originally been composed: for, as it became heavier and stiffer, it had to be made smaller.

FROM BRAUN, "DIE LITURGISCHE GEWANDUNG IM OCCIDENT UND BREISGAU)

COMPARATIVE SIZES AND SHAPES OF CHASUBLES AS NOW IN USE IN VARIOUS COUNTRIES (A & B) GERMAN, (C) ROMAN, (D) SPANISH

Decoration.—Chasubles were until the 10th century generally quite plain, and even at the close of this century, when the custom of decorating the chasuble with orphreys had become common, there was no definite rule as to their disposition. From this time onward, the embroidery became ever more and more elaborate, and the orphreys were broadened to allow of their being decorated with figures. About the middle of the 13th century, the cross with horizontal arms begins to appear on the back of the vestment, and by the 15th this had become the most usual form. Sometimes the back of the chasuble has no cross, but only a vertical orphrey, and in this case the front, besides the vertical stripe, has a horizontal orphrey just below the neck opening. This latter is the type used in the local Roman Church, which has been adopted in certain dioceses in South Germany and Switzerland, and of late years in the Roman Catholic churches in England, *e.g.*, Westminster cathedral.

The earlier decoration of the forked cross, *i.e.*, a vertical orphrey with two arms turned upwards over the shoulders, was commonly retained in England and has thus been largely adopted by the "Anglo-Catholic" clergy in modern times. Father Braun gives proof that this decoration was not even originally conceived as a cross at all, citing early instances of its having been worn by laymen and even by non-Christians. It was not until the 13th century that the symbolical meaning of the cross began to be elaborated, and this was accentuated from the 14th century onward by the custom of adding to it the figure of the crucified Christ and other symbols of the Passion. This, however, did not represent any definite rule; and the orphreys of chasubles were decorated with a great variety of pictorial subjects. The local Roman Church, true to its ancient traditions, adhered to the simpler forms. The modern Roman chasuble, besides the conventional arabesque pattern, is decorated, according to rule, with the arms of the archbishop and his see.

The Eastern Church.—The original equivalent of the chasuble is the phelonion, from the Lat. *paenula*. It is a vestment of the type of the Western bell chasuble; but, instead of being cut away at the sides, it is either gathered up or cut short in front. In the Armenian, Syrian, Chaldaean and Coptic rites it is cope-shaped. The phelonion is not in the East so specifically a eucharistic vestment as in the West, but is worn at other solemn functions besides the liturgy, *e.g.*, marriages, processions. The Greek and Greek Melchite metropolitans now wear the *sakkos* instead of the phelonion; and in the Russian, Ruthenian, Bulgarian and Italo-Greek churches this vestment has superseded the phelonion in the case of all bishops (*see* DALMATIC and VESTMENTS).

See J. BRAUN, S. J., *Die liturgische Gewandung* (1907), pp. 149–247, Dom H. Leclerq, in Cabrol, *Dict. d'Archéol. Chrét. et de Liturgie*, and the bibliography to the article VESTMENTS.

CHATALJA LINES, a fortified position 25m. W. of and covering Constantinople, extending from the Black sea at Karaburnu to the Sea of Marmara at Buyuk Chekmedje. They form a very strong position, covered in part by lakes and marshes, and commanding all the country to the west. They were first constructed during the Russo-Turkish war of 1877–78, but were not at that time the scene of fighting. During the Balkan war of 1912, however, they afforded a secure refuge to the Turkish armies defeated in the open field by the Bulgarians, and when the latter attacked them in mid-November of that year, with insufficient artillery preparation, they were repulsed with heavy loss. In the World War the lines were once more reconditioned in expectation of an Allied attack on Constantinople.

CHÂTEAU, the French word for castle (*q.v.*). The development of the castle in the 15th and 16th centuries into houses arranged rather for residence than defence led to a corresponding widening of the meaning of the term *château*, which came to be applied to any seigniorial residence and so generally to all country houses of any pretensions (*cf.* the Germ. *Schloss*). The French distinguish the fortified from the residential type by describing the former as the *château fort*, the latter as the *château de plaisance*. The development of the one into the other is admirably illustrated by the *châteaux* scattered along the Loire. Of these, Langeais, still in perfect preservation, is a fine type of the *château fort*, with its 10th century keep and 13th century walls. Amboise (1490), Blois (1500–40), Chambord (begun 1526), Chenonceaux (1515–60), Azay-le-Rideau (1521), may be taken as typical examples of the *château de plaisance* of the transition period, all retaining some of the architectural characteristics of the mediaeval castle In English the word *château* is often used to translate foreign words, *e.g.*, *Schloss*, meaning country house or mansion.

See RENAISSANCE ARCHITECTURE. For the Loire *châteaux see* Theodore Andrea Cook, *Old Touraine* (1892). (T. F. H.)

CHATEAUBRIAND, FRANÇOIS RENÉ, VICOMTE DE (1768–1848), French author, youngest son of René Auguste de Chateaubriand, comte de Combourg, was born at St. Malo on Sept. 4, 1768. He was a brilliant representative of the reaction against the ideas of the French Revolution, and the most conspicuous figure in French literature during the First Empire. His naturally poetical temperament was fostered in childhood by picturesque influences, the mysterious reserve of his morose father, the ardent piety of his mother, the traditions of his ancient family, the legends and antiquated customs of the sequestered Breton district, above all, the vagueness and solemnity of the neighbouring ocean. His closest friend was his sister Lucille,[1] a passionate-hearted girl, divided between her devotion to him and to religion. François received his education at Dol and Rennes. From Rennes he proceeded to the College of Dinan, to prepare for the priesthood, but decided, after a year's holiday at the family château of Combourg (1786) to enter the army. In 1788 he received the tonsure in order to enter the order of the Knights of Malta. In Paris (1787–89) he met La Harpe, Évariste Parny, "Pindare" Lebrun, Nicolas Chamfort, Pierre Louis Ginguené, and others, of whom he has left portraits in his memoirs. In 1791 he departed for America to take part in a romantic scheme for the discovery of the North-West Passage. The passage was not found or even attempted, but the adventurer returned from his seven months' stay in America enriched with new ideas and new imagery. In 1792 he married Mlle. Céleste Buisson de Lavigne, a girl of 17, who brought him a small fortune. He then joined the *émigrés*, and after many vicissitudes reached London, where he lived in great poverty.

From his English exile (1794–99) dates the *Natchez* (first printed in his *Oeuvres complètes*, 1826–31), a prose epic portraying the life of the Red Indians. Two brilliant episodes originally designed for this work, *Atala* and *René*, are famous. Chateaubriand's first publication, however, was the *Essai historique, politique et moral sur les révolutions* . . . (London, 1797), which the author subsequently retracted, but did not suppress. In this volume he appears as a mediator between royalist and revolution-

[1] Her *Oeuvres* were edited in 1879, with a memoir, by Anatole France

ary ideas, a free-thinker in religion, and a disciple of Rousseau. A great change in his views was, however, at hand, induced, if we accept his own statement, by a letter from his sister Julie (Mme. de Farcy), telling him of the grief his views had caused his mother, who had died soon after her release from the Conciergerie in the same year. His brother had perished on the scaffold in April 1794, and both his sisters, Lucile and Julie, and his wife had been imprisoned at Rennes. Mme. de Farcy did not long survive her imprisonment.

On Chateaubriand's return to France in 1800 the *Génie du christianisme* was already in an advanced state. Chateaubriand's favourite resort in Paris was the salon of Pauline de Beaumont, who was to fill a great place in his life, and gave him some help in the preparation of his book. *Atala, ou les amours de deux sauvages dans le désert,* used as an episode in the *Génie du christianisme,* appeared separately in 1801 and immediately made his reputation. Alike in its merits and defects the piece is a more emphatic and highly coloured *Paul et Virginie.* The *Génie du christianisme, ou beautés de la religion chrétienne,* appeared in 1802 upon the eve of Napoleon's re-establishment of the Catholic religion in France. No coincidence could have been more opportune, and Chateaubriand esteemed himself the counterpart of Napoleon in the intellectual order. The work is not to be judged by its apologetics, but as a masterpiece of literary art. Its influence in French literature was immense. The *Éloa* of Alfred de Vigny, the *Harmonies* of Lamartine and even the *Légende des siècles* of Victor Hugo may be said to have been inspired by the *Génie du christianisme.* At the moment of publication it admirably subserved the statecraft of Napoleon, and Talleyrand in 1803 appointed the writer *attaché* to the French legation at Rome, whither he was followed by Mme. de Beaumont, who died there.

When his insubordinate and intriguing spirit compelled his recall he was transferred as envoy to the canton of the Valais. The murder of the duke of Enghien (March 21, 1804) took place before he took up this appointment. Chateaubriand immediately resigned his post. In 1807 he offended Napoleon by an article in the *Mercure de France* (July 4), containing allusions to Nero which were rightly taken to refer to the emperor. The *Mercure*, of which he had become proprietor, was temporarily suppressed, and was in the next year amalgamated with the *Décade*. In 1806, he had made a pilgrimage to Jerusalem, undertaken in quest of new imagery. He returned by way of Tunis, Carthage, Cadiz and Granada. At Granada he met Mme. de Mouchy, and the place and the meeting apparently suggested the romantic tale of *Le Dernier Abencérage,* which, for political reasons, remained unprinted until the publication of the *Oeuvres complètes* (1826–31). The journey also produced *L'Itinéraire de Paris à Jérusalem . . .* (3 vols., 1811), and inspired his prose epic, *Les Martyrs, ou le triomphe de la religion chrétienne* (2 vols., 1809). *René* had appeared in 1802 as an episode of the *Génie du christianisme,* and a separate unauthorized edition appeared at Leipzig. The tale forms a connecting link in European literature between *Werther* and *Childe Harold;* it paints the misery of a morbid and dissatisfied soul. Chateaubriand betrayed amazing egotism in describing his sister Lucile in the Amélie of the story, and much is obviously descriptive of his own early surroundings. With *Les Natchez* his career as an imaginative writer is closed. In 1831 he published his *Études ou discours historiques . . .* (4 vols.) dealing with the fall of the Roman empire.

Chateaubriand's vanity and ambition made him dangerous and untrustworthy as a political associate. He was forbidden to deliver the address he had prepared (1811) for his reception to the Academy on M. J. Chénier on account of the bitter allusions to Napoleon contained in it. From this date until 1814 Chateaubriand lived in seclusion at the Vallée-aux-loups, an estate he had bought in 1807 at Aulnay. His pamphlet *De Bonaparte, des Bourbons, et de la nécessité de se rallier à nos princes légitimes,* appeared on March 31, 1814, the day of the entrance of the allies into Paris. Louis XVIII. declared that it had been worth a hundred thousand men to him. Chateaubriand, as minister of the interior, accompanied him to Ghent during the Hundred Days, and for a time associated himself with the excesses of the royalist reaction. But he rapidly drifted into liberalism and opposition, and was disgraced in Sept. 1816 for his pamphlet *De la monarchie selon la charte.* He had to sell his library and his house of the Vallée-aux-loups.

After the fall of his opponent, the duc Decazes, Chateaubriand obtained the Berlin embassy (1821), from which he was transferred to London (1822), and he also acted as French plenipotentiary at the Congress of Verona (1822). He here made himself mainly responsible for the iniquitous invasion of Spain. He was foreign minister for a brief period, and then, after another interlude of effective pamphleteering in opposition, accepted the embassy to Rome in 1827, under the Martignac administration, but resigned it at Prince Polignac's accession to office.

During the first half of Louis Philippe's reign he wrote a *Mémoire sur la captivité de madame la duchesse de Berry* (1833) and other legitimist pamphlets; but as the prospect of his again performing a conspicuous part diminished, he relapsed into an attitude of complete discouragement. His *Congrès de Vérone* (1838), *Vie de Rancé* (1844), and his translation of Milton, *Le Paradis perdu de Milton* (1836), belong to the writings of these later days. He died on July 4, 1848, affectionately tended by his old friend Madame Récamier, herself deprived of sight. For the last 15 years of his life he had been engaged on his *Mémoires,* and his chief distraction had been his daily visit to Madame Récamier, at whose house he met the European celebrities. He was buried in the Grand Bé, an islet in the bay of St. Malo. Shortly after his death appeared his celebrated *Mémoires d'outre-tombe* (12 vols., 1849–50). These memoirs undoubtedly reveal his vanity, his egotism, the frequent hollowness of his professed convictions, and his incapacity for sincere attachment, except, perhaps, in the case of Madame Récamier. Though the book must be read with the greatest caution where others are concerned, it is perhaps now the most read of all his works.

Chateaubriand is chiefly significant as marking the transition from the old classical to the modern romantic school. The fertility of ideas, vehemence of expression and luxury of natural description, which he shares with the romanticists, are controlled by a discipline learnt in the school of their predecessors. His palette, always brilliant, is never gaudy; he is not merely a painter but an artist. He is a master of epigrammatic and incisive sayings. Perhaps, however, the most truly characteristic feature of his genius is the peculiar magical touch which Matthew Arnold indicated as a note of Celtic extraction, which supplies an element of sincerity to Chateaubriand's declamation. Egotism was his master-passion. He is a signal instance of the compatibility of genuine poetic emotion, of sympathy with the grander aspects both of man and nature, and of munificence in pecuniary matters, with absorption in self and general sterility of heart.

BIBLIOGRAPHY.—The *Oeuvres complètes* of Chateaubriand were printed in 28 vols., 1826–31; in 20 vols., 1829–31; and in many later editions, notably in 1858–61, in 20 vols., with an introductory study by Sainte-Beuve. The principal authority for Chateaubriand's biography is the *Mémoires d'outre-tombe* (1849–50), of which there is an English translation, *The Memoirs of . . . Chateaubriand* (6 vols., 1902), by A. Teixeira de Mattos, based on the edition (4 vols., 1899–1901) of Edmond Biré. This work should be supplemented by the *Souvenirs et correspondances tirés des papiers de Mme. Recamier* (2 vols., 1859, ed. Mme. Ch. Lenormant). *See* also Comte de Marcellus, *Chateaubriand et son temps* (1859); the same editor's *Souvenirs diplomatiques; correspondance intime de Chateaubriand* (1858); C. A. Sainte-Beuve, *Chateaubriand et son groupe littéraire sous l'empire* (2 vols., 1861, new and revised ed., 3 vols., 1872); other articles by Sainte-Beuve, who was in this case a somewhat prejudiced critic, in the *Portraits contemporains,* vols. i. and ii.; *Causeries du lundi,* vols. i., ii. and x.; *Nouveaux Lundis,* vol. iii.; *Premiers Lundis,* vol. iii.; A. Vinet, *Études sur la litt. française au XIXe siècle* (1849); M. de Lescure, *Chateaubriand* (1892) in the *Grands écrivains français;* Émile Faguet, *Études littéraires sur le XIXe siècle* (1887); and *Essai d'une bio-bibliographie de Chateaubriand et de sa famille* (Vannes, 1896), by René Kerviler. Joseph Bédier, in *Études critiques* (1903), deals with the American writings, and there is an admirable criticism of the *Génie du christianisme* in F. Brunetière's *Hist. de la litt. française* vol. iv. (1917). Some correspondence with Sainte-Beuve was edited by Louis Thomas in 1904, and some letters to Mme. de Staël appeared in the *Revue des deux mondes* (Oct. 1903).

CHÂTEAUBRIANT, a town of western France, capital of an arrondissement in the department of Loire-Inférieure, on the

left bank of the Chère 40 mi. N.N.E. of Nantes by rail. Pop. (1954) 9,284.

It takes its name from a castle founded in the 11th century by Briant, count of Penthièvre, remains of which still exist though it was shattered in 1488. The new castle, begun in 1524 by Jean de Laval, and famous in history as the residence of Françoise de Foix, mistress of Francis I, has a beautiful colonnade running at right angles to the main building. It was presented to the department by the duc d'Aumale in 1852. The interesting Romanesque church is dedicated to St Jean de Béré. Châteaubriant is the seat of a subprefect and has a tribunal of first instance. It is a big agricultural centre with an important cattle market. Plows and agricultural machinery are made.

CHÂTEAU-D'OEX, resort Switzerland, 20 mi. from Montreux, in the Sarine valley 3,277 ft. above sea level, below the northwest end of the Bernese Oberland. Pop. (1950) 3,381. The castle was replaced by a church and the village has many attractive chalets scattered on the hillside, which are enriched with pine woods. The village is much frequented both in summer and in winter, and sports of both seasons are well developed.

CHÂTEAUDUN, a town of north central France, capital of an *arrondissement* in the department of Eure-et-Loir, 28 mi. S.S.W. of Chartres. Pop. (1954) 6,685. It stands on high ground near the left bank of the Loir. The streets radiate from a central square, the town being replanned after fires in 1723 and 1870.

Châteaudun (*Castrodunum*), a tourist centre, was the capital of the countship of Dunois in the middle ages. The castle was founded in the 10th century, rebuilt by Jean Dunois, bastard of Orléans, in the 15th century and entirely restored after 1940. It contains some ancient tapestries, and in the chapel are valuable statues. The 12th-century church of La Madeleine belonged to an abbey, the buildings of which are occupied by the law courts and hospital. The ruined chapel of Notre-Dame and the churches of St. Valerian and St Jean are mediaeval. The museum contains a unique collection of 4,000 birds, another of Egyptian objects and a library of 52,000 volumes. In 1954 a college was being built. Since 1936 agriculture has largely given place to industry, and rubber, optical instruments, machine tools and telephones are made. There is also a military air base. (H. J.-R. B.)

CHÂTEAU-GONTIER, a town of western France and chief town of the *arrondissement* of Laval, department of Mayenne, on the Mayenne, 18 mi. S. by E. of Laval. Pop. (1954) 6,720. Château-Gontier owes its origin and its name to a castle erected in the first half of the 11th century by Gontier, the steward of Fulk Nerra of Anjou, on the site of a monastery belonging to the monks of St. Aubin d'Angers. The church of St. Jean, dates from the 11th century. The town suffered severely during the wars of the League. In 1793 it was occupied by the Vendeans. It is one of the biggest agricultural centres of western France, and its fairs and markets are especially important for white geese and poultry. (A. E. D.)

CHÂTEAU-RENAULT, FRANÇOIS LOUIS DE ROUSSELET, MARQUIS DE (1637–1716), French admiral, entered the army in 1658, but in 1661 was transferred to the navy. His early services were mostly performed in cruises against the Barbary pirates; he distinguished himself in the expedition under the duc de Beaufort (1664) and in that of 1672. When war broke out between England and France in 1689 he was in command at Brest and was chosen to carry the troops and stores sent by the French king to the aid of James II in Ireland. Although he was watched by Admiral Herbert (Lord Torrington, *q.v.*) with whom he fought an indecisive action in Bantry bay he executed his mission with success. Château-Renault commanded a squadron under Tourville at the battle of Beachy Head in 1690. He was with Tourville in the attack on the Smyrna convoy in 1693. On the death of Tourville in 1701 he was named to the vacant post of vice-admiral of France.

On the outbreak of the War of the Spanish Succession, he was charged with the protection of the Spanish galleons which were to bring the treasure from America. These, with his fleet of French and Spanish warships, he brought to anchor in Vigo bay on Sept. 22 (Sept. 11, Old Style), 1702; but official obstacles delayed the landing of the cargo, and order for the transport of the bullion inland to Lugo by the Galician militia had only just arrived when, on Oct. 22, the superior Anglo-Dutch fleet under Sir George Rooke on its way back from the unsuccessful enterprise against Cadiz, appeared outside the bay. Next day the enemy broke Château-Renault's boom across the harbour, burned or captured the warships and the galleons after a savage engagement, landed troops and seized an enormous quantity of the merchandise. Louis XIV considered Château-Renault free from blame, but the Spanish government declined to give him the rank of grandee, which was to have been the reward for bringing the bullion home. He was however made a marshal of France in 1703 and lieutenant-general of Brittany in 1704. In 1708, on the death of his nephew he inherited the marquisate of Château-Renault. On Nov. 15, 1716 he died in Paris.

CHÂTEAUROUX, MARIE ANNE DE MAILLY-NESLE, DUCHESSE DE (1717–1744), mistress of Louis XV. of France, was the fifth daughter of Louis de Mailly, marquis de Nesle. She was married in 1734 to the marquis de La Tournelle who died in 1740. Her eldest sister, Louise Julie, comtesse de Mailly (q.v.), had been succeeded as the King's mistress by the next eldest, Pauline Felicite, marquise de Vintimille (1721–41). After the latter's death Madame de La Tournelle, backed by the duc de Richelieu, took her place, despite the dismay of Cardinal Fleury and the opposition of the comte de Maurepas. Her price included the definitive dismissal of Madame de Mailly from court (1742) and the title of duchesse de Châteauroux for herself (1743). She incited Louis to look for military glory, and received a letter of thanks from Frederick II. of Prussia for her part in negotiating the alliance of 1744. Louis allowed her to join him with the army at Metz, dismissed her under pressure from the church during his illness there but, recalled her to court on his recovery. She died suddenly on Dec. 8, 1744.

See E. and J. de Goncourt, *La Duchesse de Châteauroux et ses sœurs*, new ed. (Paris, 1889); also the *Histoire de Madame de Châteauroux tirée des mémoires de la Cour de Bravel* (Paris, 1910).

CHATEAUROUX, town of central France, capital of the department of Indre. Situated on the left bank of the Indre 88 mi. S. of Orléans on the main line of the Paris-Toulouse railway. Pop. (1954) 36,470. The old town close to the river forms a nucleus around which a newer and more extensive quarter bordered by boulevards, has grown up; the suburbs of St. Christophe and Déols lie on the right bank of the river. Châteauroux owes its name and origin to the castle founded about the middle of the 10th century by Raoul prince of Déols, which later passed to Henry II of England falling eventually to the Condé family (1603). The present Château-Raoul dates from the 14th and 15th centuries. The old Église des Cordeliers (13th century) and St Martial are the finest monuments. The Napoleon museum, an 18th-century house, contains a library with the oldest extant manuscript of the *Chanson de Roland* and the Breviaire Parisien, manuscript of the 15th century. Châteauroux is the seat of a prefect and of a court of assizes. It has tribunals of first instance and of commerce and a board of trade arbitrators and a chamber of commerce. Textiles and machinery are manufactured, and there is a state tobacco factory. (A. E.)

CHÂTEAU-THIERRY, a town of northern France in the department of Aisne, 59 mi. E.N.E. of Paris on the Eastern railway to Nancy. Pop. (1946) 7,691. Château-Thierry is built on rising ground on the right bank of the Marne, over which a fine stone bridge was built, connecting it with the suburb of Marne. On the top of a hill are the ruins of a castle, said to have been built by Charles Martel for the Frankish king, Thierry IV, whence the name of the town. The chief relic is a gateway flanked by massive round towers, known as the Porte Saint-Pierre. A belfry of the 15th century and the church of St. Crépin (Crispin) of the same period are of some interest.

Château-Thierry was formerly the capital of the district of Brie Pouilleuse, and received the title of duchy from Charles IX in 1566. It was captured by the English in 1421, by Charles V in 1544, and sacked by the Spanish in 1591. During the wars of the Fronde it was pillaged in 1652; and in the campaign of 1814 it suffered severely, under Blücher, the Russo-Prussian forces being beaten by Napoleon in the neighbourhood. It was the farthest point reached by the Germans in their offensive of May 27, 1918. The 2nd and 3rd divisions of the American Expeditionary force were sent to the Marne in the Château-Thierry region to assist the hard-pressed French forces. At Château Thierry itself a U.S. machine-gun battalion took part in the successful defense of the river crossing, while to the west of the town the 2nd division, under Gen. Omar Bundy, fought the fiercely contested engagement of Belleau Wood.

(*see* GERMAN OFFENSIVE, 1918; MARNE, SECOND BATTLE OF THE)

La Fontaine was born in the town in 1621. His house is still preserved in the street that bears his name

The distinctive industry is the manufacture of mathematical and musical instruments. There is trade in the white wine of the neighbourhood, and in agricultural products. Gypsum, millstone and paving stone are quarried in the vicinity.

CHÂTELAIN, in France originally merely the equivalent of the English castellan, *i.e.*, the commander of a castle. With the growth of the feudal system, however the title gained in France a special significance which it never acquired in England, as implying the jurisdiction of which the castle became the centre

The *châtelain* was originally, in Carolingian times, an official of the count; with the development of feudalism the office became hereditary, and so ultimately hereditary. In this as in other respects the *châtelain* was the equivalent of the viscount (*q.v.*); sometimes the two titles were combined, but more usually in those provinces where there were *châtelains* there were no viscounts, and vice versa

The title *châtelain* continued also to be applied to the interior officer or *concierge châtelain*, who was merely a castellan in the English sense The power and status of *châtelains* necessarily varied greatly at different periods and places; occasionally they were great nobles with an extensive jurisdiction as in the Low Countries

The *châtellenie* (*castellania*), or jurisdiction of the *châtelain*, as a territorial division for certain judicial and administrative purposes survived the disappearance of the title and office of the *châtelain* in France, and continued till the Revolution

See Achille Luchaire, *Manuel des institutions françaises* (1892); Du Cange, *Glossarium*, s. "Castellanus."

CHATELAINE, the mistress of a castle. From the custom of a châtelaine of carrying the keys of the castle suspended from her girdle, the word was applied in the late 19th century to the collection of short chains, worn by ladies, to which keys, penknife, needlecase, scissors, etc., were attached.

CHÂTELET, EMILIE DE BRETEUIL, MARQUISE DU (1706–1749). French mathematician and physicist, daughter of Louis Nicholas le Tonnelier, Baron de Breteuil, was born in Paris on Dec. 17, 1706. Her father gave her a solid classical training, and she added knowledge of English and Italian. She was also an accomplished musician. When she was 19 she married the marquis Florent du Châtelet and they had three children. Although she participated in the social life of the Regency, she became a serious student of metaphysics, physics and chemistry. While studying with Samuel Koenig she wrote *Institutions de physique* (1740), an exposition of the philosophy of Gottfried Leibnitz. She was the first to translate Isaac Newton's *Principia Mathematica* into French. Her translation, prefaced by Voltaire, was published in 1756 after her death under the direction of Alexis Clairault.

Both because of her scientific writings and her long close relationship with Voltaire, to whom she was introduced about 1733, Émilie du Châtelet won renown. She and Voltaire spent the next 15 years together, living most of the time at Cirey, the château of the Du Châtelets in Champagne. The residence served as a quiet haven for their studies and as a refuge from the Paris police who were often on the trail of Voltaire. On those occasions when he ran into trouble with the authorities, she exerted considerable power at court to extricate him.

Her scientific training enabled her to render Voltaire invaluable assistance and to stimulate his interest in science and in metaphysics. After Madame du Châtelet had protested against the conventional type of written history, which she called "nothing but an old almanac," Voltaire composed his *Essai sur les moeurs et l'esprit des nations,* which, with its emphasis on the social and intellectual forces that had shaped history, marked a departure in historical writing.

Even after Émilie du Châtelet had transferred her affections to the poet Jean de Saint-Lambert, she and Voltaire remained close friends. They were visiting at the court of Stanislas of Poland in Lunéville when she died on Sept. 10 1749, in childbirth.

Other works by Madame du Châtelet include *Réponse à la lettre de Mairon sur la question des forces vives* (Brussels, 1741); *Doutes sur les religions* (Paris, 1792); *Réflexions sur le bonheur* (Paris, 1796); and M. Asse (ed.) *Lettres* (Paris, no date).

Libby, *The Attitude of Voltaire to Magic and the Sciences* (1935); A. Maurel, *The Romance of Madame du Châtelet and Voltaire* (1931); and Ira Wade, *Voltaire and Madame du Châtelet, an Essay on the Intellectual Activity at Cirey* (1941), which emphasizes Madame du Châtelet's work on Biblical criticism.

CHÂTELET, the word used in France for a building designed for the defense of an outwork or gate, sometimes of great strength, but distinguished from the *château*, or castle proper, in being purely defensive and not residential (from Med. Lat. *castella*).

In Paris, before the Revolution, this word was applied both to a particular building and to the jurisdiction of which it was the seat. This building had been first a castle defending the approach to the Cité. Tradition traced its existence back to Roman times, and in the 18th century one of the rooms in the great tower was still called *Caesar's room*. The jurisdiction was that of the provostship (prévôté) and viscountship of Paris, which was of feudal origin, probably going back to the counts of Paris.

It was not till the time of St. Louis that, with the appointment of Étienne Boileau, the provostship of Paris became a public office no longer put up to sale (*prévôté en garde*). When the *baillis* (*see* BAILIFF AND BAILIE) were created, the provost of Paris discharged the functions of a *bailli*, in which capacity he heard appeals from the seigniorial and inferior judges of the city and its neighbourhood, keeping, however, his title of provost. When under Henry II certain *bailliages* became presidial jurisdictions (*présidiaux*), *i.e.*, received the right of judging without appeal, the Châtelet was made a presidial court. Finally, various tribunals peculiar to the city of Paris, *i.e.*, courts exercising jurisdictions outside the common law or corresponding to certain *cours d'exception* which existed in the provinces, were united with the Châtelet, of which they became divisions (*chambres*). Thus the lieutenant general of the police made it the seat of his jurisdiction, and the provost of the Île de France, who had the same criminal jurisdiction as the provosts of the marshals of France in other provinces, sat there also. As to the *personnel* of the Châtelet, it was originally the same as in the *bailliages*, except that after the 14th century it had some special officials, the auditors and the examiners of inquests. Like the *baillis*, the provost had lieutenants who were deputies for him, and in addition gradually acquired a considerable body of *ex officio* councillors. This last staff, however, was not yet in existence at the end of the 14th century, for it is not mentioned in the *Registre criminel du Châtelet* (1389–92).

In 1674 the whole *personnel* was doubled at the time when the new Châtelet was established side by side with the old, the two being soon after amalgamated. On the eve of the Revolution it comprised, besides the provost whose office had become honorary, the *lieutenant civil* who presided over the *chambre de prévôté au parc civil* or court of first instance; the *lieutenant criminel*, who presided over the criminal court; two *lieutenants particuliers*,

THE CHÂTELET, PARIS, ORIGINALLY A FORTRESS, LATER A PRISON AND COURTHOUSE, AS IT LOOKED BEFORE ITS DESTRUCTION IN 1802

powered the Châtelet to try cases of *lèse-nation*. It was before this court that was opened the inquiry following on the events of Oct. 5 and 6, 1789 (Louis' removal to Paris). It was suppressed by the law of Aug. 16, 1790, together with the other tribunals of the *ancien régime*. The site of the building still bears the name of Châtelet. (J. P. E.; X.)

CHÂTELLERAULT, a town of western France, capital of an arrondissement in the department of Vienne, 19 mi. N.N.E. of Poitiers on the Orleans railway. Pop. (1946) 22,809. It is situated on the right bank of the Vienne and is connected with the suburb of Châteauneuf by a stone bridge of the 16th and 17th centuries. Châtellerault (or Châtelherault: *Castellum Airaldi*) derives its name from a fortress built in the 10th century by Airaud, viscount of its territory. In 1515 it was made a duchy in favour of François de Bourbon, but was soon reunited to the crown. In 1548 it was bestowed on James Hamilton, 2nd earl of Arran (*see* HAMILTON). The manufacture of cutlery dates from the 14th century and is carried on in villages along the banks of the Clain. The most important industrial establishment is the national small-arms factory, established in 1819.

CHATHAM, WILLIAM PITT, 1ST EARL OF (1708–1778), was born at Golden square, Westminster, on Nov. 15, 1708. His father was Robert, son of the famous Governor Pitt of Madras; his mother Harriet Villiers, daughter of Viscountess Grandison. He was the fourth child of a family of seven, most of whom showed signs of mental instability. He was educated in the classics at Eton and Trinity college, Oxford. At Eton he made friends with many who later became his political associates, and especially with George Lyttelton, Henry Fielding, Charles Pratt and Charles Hanbury Williams. He left Oxford after only one year, partly because of the persistent gout from which he already suffered, and spent some months studying law at the University of Utrecht. A large number of deaths among the influential members of his family when he was still only 20 left his career uncertain, but his steps were guided toward politics by the marriage, in 1728, of his brother to Christian Lyttelton, sister of his school friend George Lyttelton. Through the Lytteltons the Pitts became connected with the widely ramified clan of the Temples and Grenvilles, one of the most powerful groups in the land-owning oligarchy which, under the Hanoverian monarchs, virtually governed Britain. The leader of the group, Viscount Cobham, wielded great wealth and patronage and it was through his gift that William, in 1731, was appointed a cornet in the king's own regiment of horse, which later became the 1st dragoon guards. This commission brought him an income of £150 a year and an introduction to court and public life.

In 1735 he entered the house of commons as member for Old Sarum, one of his brother's pocket boroughs, which later became the most notorious example of all pocket boroughs. He belonged inevitably to the group of "Cobham's cubs," the connection of family friends and place hunters whom Cobham was mobilizing to oppose the ministry of Sir Robert Walpole. Calling themselves "patriots," they joined with discontented Whigs like Lord Carteret and William Pulteney and Hanoverian Tories like Sir William Wyndham to rally the opposition forces behind the prince of Wales, Frederick Louis. At a time when a regular standing opposition in parliament was generally regarded as factious and even traitorous, since ministers were the king's ministers, it became common for political groups opposed to the government to seek respectability by alliance with the heir to the throne. Since it was normal for Hanoverian monarchs to be in a state of violent hostility with their eldest sons, royal power was habitually divided against itself. Politicians excluded from office looked to "the rising sun," and the prince of Wales used both his own patronage and the hopes of future office to unite them against his father and his father's ministers. At this time Viscount Bolingbroke was especially active in his efforts to form in this way a solid opposition to Walpole. So Pitt entered parliament at a crucial stage of party development. His maiden speech provoked reprisals from Walpole, who deprived him of his military commission in an effort to "muzzle this terrible cornet of horse."

In 1737 the prince of Wales made him a groom of the bedchamber with a salary of £400 a year. Despite his status as a relatively poor dependent of a powerful Whig clan, and as a pensioner of the prince of Wales, Pitt already showed some appreciation of that independence of mind and that appeal to popular support which were to gain him unique personal prestige in English political life. His talents as an orator had become clear. His exploitation of the position of patriotic martyr, by driving around the southern counties after his dismissal by Walpole, showed a readiness to appeal to public opinion outside parliament, as well as his lively sense of the histrionic. He repeatedly referred to the "voice of England," which had to be sought outside parliament because parliament was so packed with place men and sinecurists. He claimed to speak for the commercial interests and even the colonists oversea, both scarcely represented in the commons. Although the member for Old Sarum could hardly claim directly to represent such interests, he more and more put forward arguments that would logically deny the whole system of oligarchical control over the electorate and over parliament. If he was a Whig he was, par excellence, a wayward Whig, using in the cause of opposition arguments which carried far beyond the close oligarchy enjoyed by the Whig families.

When Walpole at last fell from power in 1742 he was replaced by a ministry which included his old colleagues the duke of Newcastle and Lord Hardwicke, with Carteret as secretary of state. Pulteney was silenced by a peerage. The "boy patriots," of whom Pitt was by now the acknowledged parliamentary leader, were still excluded from power. They were left with no option but to oppose Carteret even more vehemently than they had attacked Walpole.

From 1741 to 1748 Great Britain was engaged in the complex diplomacy and strategy of the War of the Austrian Succession. The chief menace to British security was Bourbon power in Europe, and the aim of British policy was therefore to diminish French power in every way possible. Pitt differed from Carteret more about means than about ends. George II and Carteret saw the issue as primarily a continental one and aimed at a coalition of German states, led by Britain and Hanover, to support Maria Theresa of Austria in her struggle against France. Pitt insisted

that Great Britain should concentrate on attacking France where it was most vulnerable and where British naval power brought the greatest advantage—that is, in France's colonial possessions, which obstructed British enterprise and expansion in America and India. He accordingly attacked, in a series of great speeches, the government's policy of continental alliances and subsidies and exploited the unpopularity of the royal connection with Hanover. Carteret was condemned as "a Hanover troop minister," and as "an infamous minister who seems to have renounced the name of an Englishman." It was possible to be a "patriot" in a new and additional sense, and to appeal to every sort of national and popular prejudice.

When Carteret was forced to resign in 1744 Newcastle and his brother, Henry Pelham, took office. They wanted to include Pitt but George II had been so offended by Pitt's attacks on Hanover that he refused to accept him. During the Jacobite rising of 1745 Pitt gained new stature as the one statesman of effectiveness and vigour; and the rising was itself a further argument against the continental policy of the king. In Feb. 1746 the king agreed to appoint Pitt joint vice-treasurer of Ireland at £3,000 a year, and two months later he became paymaster general of the forces. His first ten years in parliament had been spent in opposition and he had earned a formidable reputation as a *frondeur*. His acceptance of the paymastership, which was notoriously the richest plum of place hunters, at first caused bewilderment and recriminations, even from his friends. It seemed that the "patriot" had been bought by the government. But it gave Pitt a further opportunity to earn a unique reputation for honesty and disinterestedness. He renounced for himself all the rich perquisites of the office except its official salary of more than £4,000. He also introduced many useful reforms in the administration of the office and dramatically regained his reputation for both scrupulous honesty and efficiency. He held the office for nine years and left it still a poor man.

But a legacy of £10,000 from the old duchess of Marlborough enabled him to indulge in more lavish expenditure and generosity. He spent a good deal on landscape gardening and bought South lodge at Enfield. In 1754 he married Hester Grenville and thereafter found, in a supremely happy home life, a new source of strength and escape from his somewhat solitary existence. In policy he supported the Pelhams' alliance with Hanover, but tried to strengthen British naval power as the chief weapon of both offense and defense. When Henry Pelham died, in 1754, Pitt hoped to become leader of the house of commons. The duke of Newcastle, jealous of Pitt's abilities and distrustful of his only serious rival, Henry Fox, manoeuvred into office a colourless nonentity, Sir Thomas Robinson. Pitt and Fox joined in baiting and ridiculing Robinson, but when he was driven to resign it was Fox whom Newcastle took in as secretary of state. Pitt transferred his attacks to the Newcastle-Fox combination, likening it to "the conflux at Lyons of the Rhône and the Saône: this a feeble, languid stream, and, though languid, of no depth—the other a boisterous and overbearing torrent—but they meet at last." The jibe cost him the pay office, from which he was dismissed in 1755.

The outbreak of the Seven Years' War gave Pitt his supreme opportunity for statesmanship. It began with heavy losses and considerable confusion of policy. The popular demand for Pitt became irresistible, and he declared "I know that I can save this country and that no one else can." In Nov. 1756 he formed a ministry which excluded Newcastle, with the duke of Devonshire as its nominal head. In June 1757 Newcastle returned to office on the understanding that he should control all the patronage and leave Pitt to conduct the war. It proved to be an admirable division of labour.

Pitt determined that it should be in every sense a national war and a war at sea. He got rid of the German mercenaries who had been sent over to resist invasion and revived the militia, which was made into a serviceable defense force. He re-equipped and reorganized the navy. He sought to unite all parties and public opinion behind a coherent and intelligible war policy. He seized upon America and India as the main objects of British strategy. He sent his main expeditions to America, to ensure the conquest of Canada; and supported the East India company and their "heaven-born general" Robert Clive in their struggle against the French East India company. He also subsidized and reinforced the armies of Frederick the Great of Prussia, so as to engage the main French armies on the continent, while he used naval power to harrass the French on their own coasts, in the West Indies and in Africa. He chose good generals and admirals—James Wolfe, Jeffrey Amherst, and Edward Boscawen, Edward Hawke, Charles Saunders, George Pocock, Charles Watson—and he inspired them with a new spirit of dash and enterprise. Against so resolute and concerted a policy the Bourbon powers even in alliance could not avail. At the treaty of Paris in 1763 Great Britain remained supreme in North America and India, held Minorca as a Mediterranean base and gained territory in Africa and the West Indies. Pitt had given Britain a new empire as well as preserving and consolidating the old.

But before the war ended Pitt had been forced to resign. In 1760 George III came to the throne resolved, as was his chief adviser Bute, to end the war as speedily as possible. When Pitt failed to persuade his colleagues to forestall Spain's entry into hostilities by an immediate declaration of war he resigned, in Oct. 1761. He had tended to concentrate the whole conduct of government into his own hands and had worked with a furious energy. His haughty and aloof manner, which alienated so many of his colleagues, and his high-handed treatment of affairs, rendered tolerable only so long as he was proved right, had earned him respect and admiration but little friendship. When his resignation was accompanied by the grant of a peerage to Hester and an annuity of £3,000 a year for himself, there was again an outburst of abuse and scurrility. Just as when he had accepted the pay office, this acceptance of a peerage and a pension seemed to be the result of a political bargain and a sordid anticlimax to so brilliant a career. As rewards for his immense services they were meagre enough; but it is some measure of the unique repute for high-minded disinterestedness which he had won that his acceptance of such rewards should provoke so much bitter disillusionment. His effigy was burned in the City, and Hester was reviled as Lady Cheat'em.

He attacked the terms of the treaty of Paris as an inadequate recognition of Great Britain's world-wide successes. The intense unpopularity of Bute and Pitt's role as champion of national rights soon restored his popular appeal. But his career as a war minister was now over. He had delivered 115 speeches since he had entered parliament and more than half of them had been concerned with war or preparations for war. As a supremely successful secretary of state during the Seven Years' War he had combined colonial and naval operations with containing operations in Europe, and had shown that they were not alternative theories of strategy but were complementary. The rest of his political career was devoted to attempting a similar reconciliation of principles: of imperial power with constitutional liberty.

When Bute resigned in April 1763, he was succeeded by George Grenville. Pitt's attacks on his administration completed the breach between the two brothers-in-law. He condemned the action taken by the ministry against John Wilkes, for his attack on the king's speech in no. 45 of the *North Briton*, and opposed Grenville's Stamp act. He took no active part in politics between 1764 and 1766, and was now becoming subject to the recurrent fits of manic-depressive insanity which were to cloud the rest of his life. In 1765 he was left, by Sir William Pynsent, the estate of Burton Pynsent in Somerset, worth more than £3,000 a year. In Jan. 1766 he re-entered the stage with a passionate appeal for imperial liberty. Of the American colonists, who had resisted the Stamp act, he proclaimed, "as subjects they are entitled to the common right of representation, and cannot be bound to pay taxes without their consent." He supported and defended their resistance and demanded the complete repeal of the Stamp act. This was done, but replaced by a Declaratory act maintaining the right of taxation. Grenville's successors, the Rockinghams, found their position equally untenable and in July 1766 the king asked Pitt to form a ministry drawn from all sections of the house.

The idea of an all-party ministry had long haunted English politics. Parties were regarded as factions and the unit of parliamentary politics was not party but aristocratic group connection. Every ministry was a combination of several such groups and the groups excluded tended to form an opposition until some of them, at least, were offered places. While the notion of a regularly formed opposition was viewed with much distrust, it was natural to seek strength for government in a "broad-bottomed" or all-party administration. Pitt had propounded the view that a ministry should be formed on the principle of "measures and not men"; that is, that ministers should be appointed for their abilities and policies, and not because of their group connections. This has often been assumed to mean agreement with the aims of George III, who in his efforts to recover for the crown the use of royal patronage which the first two Georges had allowed to fall into the hands of the Whig oligarchy, was seeking a ministry similarly united on principles rather than on group affiliations. But Pitt's interests were different. He was not concerned to attack the system of group connections, but rather to insert himself, alongside the oligarchic leaders, as an individual who should be indispensable to any effective administration. He played, by instinct and temperament, something of a lone hand in politics. His main principle was that the king's government must be carried on, and what he wanted was strong, coherent and efficient administration. In 1763 he told the king that "it cannot be carried on without the great families who have supported the Revolution Government, and other great persons of whose abilities and integrity the public have had experience, and who have weight and credit in the nation." He repeatedly showed that he had no wish to destroy the oligarchic groups, but was perfectly willing to collaborate with them so long as they would acknowledge his own unique position and influence. Accordingly, his ministry of 1766 included Henry Conway and Lord Northington from the previous ministry, Lord Camden, Lord Grafton and Lord Shelburne who were his own followers, and Lord North and Charles Townshend. It could have worked well only if Pitt himself had remained in active control over it. But he accepted an earldom and took the almost sinecure post of lord privy seal. The "great commoner" retired to the lords, and fell ill for another two years. The luckless duke of Grafton was left in nominal control of the government just when the disturbances in America and in Middlesex, over the Wilkes elections case, were reaching their climax.

The new ministry was probably doomed to failure from the start. Its members held contrary views about America, and had little harmony of temperament or purpose. It is doubtful if even Chatham could have made them into a team; certainly the indolent Grafton could not. Engulfed in a black fit of insanity, Chatham withdrew completely and, in 1768, resigned office. His own chancellor of the exchequer, Townshend, imposed a series of duties on the American colonists which brought in little revenue but caused widespread discontent. He appeared in the lords in 1770 to launch a savage attack on the ministry, and on the house of commons for its surrender to the wishes of the king in the Middlesex elections, when it not only expelled Wilkes but illegally declared the defeated candidate, H. L. Luttrell, elected. He supported the City in its protests against the government and demanded a dissolution to get rid of a subservient commons. He even proposed a measure of parliamentary reform to strengthen the county representation as against the boroughs, the "rotten parts" of the constitution. In the following year he pressed for triennial, instead of septennial, elections, as a method of bringing the commons more closely into touch with public opinion in the country. His early "radical" propensities came more into the open.

During the last ten years of his life, 1768–78, he acquired a group of followers of his own, including Grafton, Shelburne, Camden and Isaac Barré. In parliamentary action he was driven to rely more upon this group and less upon his own eloquence and popularity. Instead of being able, in Burke's words, "to keep hovering in air, over all parties, and to souse down where the prey may prove best," he was driven into active alliance with the Rockingham group. He was forced into the normal Whig procedure of negotiating group alliances and in his deliberate disruption of the Grafton ministry in 1770 he acted little differently from the ordinary party man in opposition. The end of his career showed that there was little permanent place, in 18th century politics, for one who claimed to depend primarily upon a personal reputation for ability and disinterestedness. In the end he, like the king himself, found that he had to come down into the arena and deal with politicians and group connections on their own ground.

His last years were clouded by illness and only on rare occasions did he emerge from seclusion to appeal for a more generous and understanding treatment of America. Yet he broke with the Whig groups when they were prepared to recognize the independence of the 13 colonies and when the Americans had allied with Britain's traditional enemy, France. His last speech in the lords was a protest against any diminution of an empire based on freedom. In 1775 he hurriedly introduced a bill designed to suspend repressive measures in Boston, maintain the legislative authority of parliament over the colonies, and yet use the Continental congress established at Philadelphia as a body for assessing the monetary contributions of each colony. The bill was summarily rejected, but is the best indication of how Chatham would have handled the American problem.

After 1771 it was his practice to emerge only occasionally as the elder statesman, to promote or attack individual measures, but not to attempt, as in 1770, to overthrow the ministry as a whole. He spent most of these years enjoying the life of a country gentleman, or in gloomy seclusion as an invalid. He died at Hayes, Middlesex on May 11, 1778 and was buried in Westminster abbey.

Chatham remains a brilliant and dominant yet enigmatic figure in 18th century history. Even the fragmentary reports of his speeches which survive endorse his contemporary reputation: one of the greatest orators that England has ever known. As war minister he combined immense breadth of vision with brilliant executive ability. As a statesman, he raised British power and prestige to great heights, and added large territories to Britain's overseas possessions. As a man he was a model of devotion to his family as well as of unstinted public service. But his genius was erratic, his political behaviour at times factious and at variance with his professed principles. The penalty of his eminence was a certain isolation. He had the defects of spiritual pride and haughtiness, which were perhaps the natural counterparts of his great talents.

His role in the development of the English party system is ambiguous. He did not seek to destroy the system of aristocratic patronage and group connection in politics, yet he in effect did much to undermine their power and to introduce into parliamentary life the force of public opinion. By his sustained and vigorous opposition to ministers such as Walpole, Carteret, Fox, Bute, Grenville and Grafton, he established a powerful tradition of the merits and rights of an organized opposition in parliament, yet this development seemed to be denied by his support for the idea of an all-party administration based on "measures and not men." He had a less profound insight than his contemporary Edmund Burke, into the basic implications of a constitutional parliamentary system. He remains none the less, one of the greatest geniuses of statecraft in British history.

CHATHAM, an incorporated town and port of entry in Northumberland county, New Brunswick, Canada, with good harbour on the Miramichi river, 24 mi. from its mouth and on the Canadian National railway. Pop. (1951) 5,223. The town contains a Roman Catholic pro-cathedral. The chief industries are

saw mills, pulp mills and fish curing plants. Ships load millions of feet of lumber annually for foreign markets. (C. Cy.)

CHATHAM, a city and port of entry of Ontario, Canada, and the capital of Kent county, 64 mi. S.W. of London and 11 mi. N. of Lake Erie, on the Thames river and the Canadian National, Canadian Pacific, Chesapeake and Ohio, and Wabash railways. Pop. (1951) 21,218. It has steamboat connection with Detroit and the cities on Lakes Huron and Erie. It is situated in a rich agricultural and fruit-growing district, and carries on a large export trade. It contains canneries, planing and flour mills, manufactories of fanning mills, binder-twine, woven-wire goods, engines and auto parts, and a large beet sugar factory. (C. Cy.)

CHATHAM, a port and municipal borough in the parliamentary division of Rochester and Chatham, Kent, Eng., on the right bank of the river Medway 10 mi. above its confluence with the Thames and about 30 mi. E.S.E. of London by road. Pop. (1951) 41,231. Area 6.8 sq.mi. Though a distinct borough, it is coterminous with Rochester on the west and forms, with it and Gillingham on the east, one large conurbation of which Chatham is the principal shopping, commercial and entertainment centre. Industries include flour mills, timber works, etc., but by far the biggest employer is the royal naval dockyard.

Chatham (*Ceteham, Chetham*) belonged at the time of Domesday to Odo, bishop of Bayeux. It later formed a suburb of Rochester, but Henry VIII and Elizabeth I established dockyards and an arsenal. The dockyard was altered and improved by Charles I and Charles II and became the chief naval station of England. In 1708 an act was passed for extending the fortifications of Chatham, and the town grew around the dockyard.

The royal naval dockyard is situated to the north of the town, on a point, partly of reclaimed marsh, beyond which the sharply curving river widens from about 400 yd. to its broad tidal estuary. The dockyard covers more than 500 ac. and has a river frontage of more than 3 mi. It is equipped both for building and repairing naval vessels of all kinds. There is a church in the dockyard, and near at hand are the royal naval, royal marine and royal engineers barracks. Chatham has a number of striking memorials to members of the services in various campaigns. A series of open spaces on the hill east of the town are known as the "Chatham Lines." On this hill a number of forts were erected to defend the position during the Napoleonic wars; conspicuous on the heights is the Royal naval war memorial. Just below Fort Amherst is the town hall. Fort Pitt was adapted to house a girls' technical school. The High street is formed by part of the ancient Watling street connecting Canterbury and London.

St. Mary's church occupies a site in similar use since Saxon times. Norman and Early English features from the old church, which was destroyed by fire, are incorporated in the present 18th century building (thoroughly restored in 1903). The church contains a memorial to Stephen Borough (d. 1584) who in 1553 discovered the northern passage to Archangel. Near the railway station is a monument to Thomas Waghorn (d. 1850), a Chatham man who founded the overland route to India. St. Bartholomew's chapel, originally attached to the hospital for lepers founded by Gundulph, bishop of Rochester in 1078, is partly Norman. The hospital still has connections with Rochester cathedral. The Hospital of Sir John Hawkins, knight, in Chatham, for ex-seamen and shipwrights of Chatham and Sheerness dockyards, was founded in 1592 by Sir John Hawkins and rebuilt in the middle of the 18th century. The fund called the Chatham Chest, originated by Hawkins and Drake in 1588, was incorporated with Greenwich hospital in 1802.

Charles Dickens and his family lived from 1817 to 1821 in a house at Ordnance terrace, where his father worked in the navy pay office, and Chatham people were the originals of certain characters in *Sketches by Boz* and *David Copperfield*.

Chatham was constituted a parliamentary borough by the Reform bill of 1832. In 1918 the municipal boroughs of Chatham, Gillingham and Rochester combined to return two members to parliament. The town, with the suburb of Luton, was incorporated in 1890.

CHATHAM ISLANDS, a small group of islands in the Pacific ocean forming part of New Zealand, 450 mi. due E. of Lyttleton, in South Island, in about 44° S., 177° W. It consists of three islands, a large one called Whairikauri, or Chatham Island, a small one, Rangihaute, or Pitt Island, and a third, Rangatira, or South-East Island. There are also several rocky islets. Whairikauri, of which the highest point reaches about 1,000 ft., is remarkable for the number of small lakes it contains. Its form is irregular, being about 38 mi. in length and 25 mi. in extreme breadth, with an area of 321 sq. miles. The geological structure (mainly volcanic rocks with schists and Tertiary limestone) indicates that the islands were once part of New Zealand. In general, the soil is extremely fertile, and where it is naturally drained a rich vegetation of fern and flax occurs. On the southwestern side is Petre bay, on which, at the mouth of the river Mantagu, is Waitangi, the main settlement.

The islands were discovered in 1791 by Lieutenant W. R. Broughton (1762–1821) who gave them the name of Chatham after the earl of Chatham. He called the natives Morioris or Maiorioris. In 1831 they were conquered by 800 Maori who were landed from a European vessel. The natives were almost exterminated, and disease killed off most of the remainder. Their language was akin to that of the Maori of New Zealand, though they differed from them physically. Cattle and sheep are bred. At one period whalers visiting these seas used to call at the Chathams for supplies. The chief exports are wool and fishery products, particularly frozen fish. The area of the group is 372 sq.mi. In 1945 the population on all islands totalled only 505 (290 Europeans and 215 Maori). The 1951 total was 471.

There are no indigenous mammals; the reptiles belong to New Zealand species. The birds—the largest factor in the fauna—have become very greatly reduced through the introduction of cats, dogs and pigs, as well as by constant destruction. The larger bellbird is now scarce, the fruit-pigeon and the two endemic rails are extinct. The fossil avian forms are very important, especially from the point of view of the geographical distribution of species and the survival of the older forms in these remote corners. There have been discovered the remains of a species of swan belonging to the South American genus *Chenopis*, and of the tuatara (*Hatteria*) lizard, the unique species of an ancient family now surviving only in New Zealand. One of the finest of the endemic flowering plants of the group is the boraginaceous "Chatham Island lily" (*Myositidium nobile*), and a gigantic forget-me-not, growing on the shores. Dracophyllums leucopogous, and arborescent ragworts are characteristic forms in the vegetation.

CHÂTILLON-SUR-SEINE, a town of eastern France, in the department of Côte-d'Or, on the Eastern and P.L.M. railways, 67 mi. N.N.W. of Dijon. Pop. (1946), 4,109. It is situated on the upper Seine, which is here joined by the Douix, the source of which is much visited. Châtillon, an old feudal town, anciently consisted of two parts, Chaumont, belonging to the duchy of Burgundy, and Bourg, ruled by the bishop of Langres; they did not coalesce till the end of the 16th century. It was taken by the English in 1360 and by Louis XI in 1475, during his struggle with Charles the Bold. Châtillon was one of the first cities to adhere to the League, but suffered severely from the oppression of its garrisons and governors. It is associated with the abortive conference of 1814 between the representatives of Napoleon and the Allies. The ruined 13th century castle of the dukes of Burgundy lies above the town. Near by stands the church of St. Vorles, begun in the 10th century, but with many additions; it contains a sculptured Holy Sepulchre of the 16th century and a number of frescoes. Marshal Marmont, duke of Ragusa was born at Châtillon in 1774, and built a château here. Its industries include iron-founding and the manufacture of agricultural machinery.

CHATSWORTH, the principal seat of the dukes of Devonshire, in the parish of Edensor, Derbyshire. Chatsworth house stands close to the left bank of the River Derwent, 2¾ mi. E.N.E. of Bakewell. The park is more than 11 mi. in circumference. The house is built around a large open courtyard which has a fountain in the centre. The gardens are adorned with sculptures by Gabriel Cibber and its fountains are said to be surpassed only by those at Versailles. The house contains a library and art

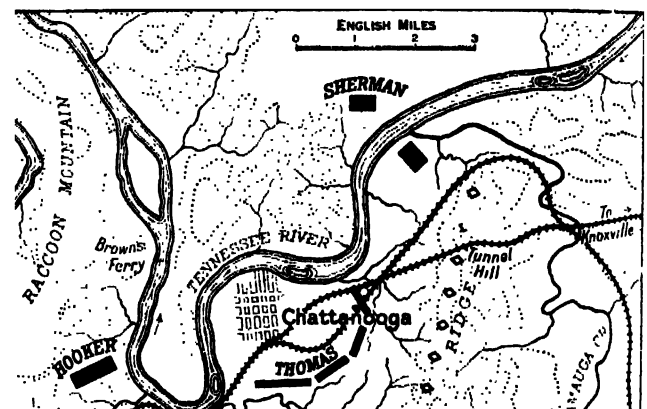
collection which includes works by Reynolds, Holbein, Dürer, Memlinc, Murillo, Dolci, Veronese, Titian, Michelangelo, Leonardo da Vinci and Correggio, and sculptures by Canova, Bertel Thorwaldsen, Chantrey and R. J. Wyatt. Beyond the river, and immediately opposite the house, is the model village of Edensor: of Saxon origin, it was almost entirely rebuilt by the 6th duke. The parish church, built by Sir Gilbert Scott to replace a much older building, contains a brass in memory of John Beaton, confidential servant to Mary queen of Scots.

Chatsworth (*Chetesworde, Chattesworth,* "Ceatt's homestead") took its name from Ceatt, one of its Saxon owners. It was entrusted by William the Conqueror to the custody of William Peverel. It afterward belonged for many generations to the family of Leech, and was purchased in the reign of Elizabeth I by Sir William Cavendish, husband of the famous Bess of Hardwick. In 1553 he began to build Chatsworth house, which was completed, after his death, by his widow, later countess of Shrewsbury. Here Mary queen of Scots spent several years of her imprisonment under the care of the earl of Shrewsbury. During the Civil War, Chatsworth was occupied as a fortress by both parties and subsequently pulled down. The present house was designed by William Talman for the 4th earl (created 1st duke in 1694). Although a marble slab in the Great hall states that it was begun in 1688, work was already in progress in 1687. The long north wing was added (1820–27) by Sir Jeffry Wyatville for the 6th duke who also extended the east side (1827–34) and rebuilt the interior of the south wing.

CHATTANOOGA, a city of Tennessee, U.S., on the Tennessee river, at the southern boundary of the state adjoining Georgia; county seat of Hamilton county. It is at the intersection of federal highways 11, 27, 41 and 64.

It is served by the following railroads: Southern, Nashville, Chattanooga and St. Louis, the Central of Georgia and the Tennessee, Alabama and Georgia. By air it is served by Capital, Delta, and Eastern air lines. The Tennessee river is navigable all year round, and river steamers and barges supplement the city's transportation requirements. The land area of the incorporated city is 27.4 sq.mi. The population by the 1950 federal census was 130,333; in 1940 it was 128,163.

Chattanooga is the geographic centre and largest city of the Tennessee Valley authority's development program.



The mile-long $36,000,000 Chickamauga dam is in the northern outskirts of the city; the Watts Bar dam and Hales Bar dam are near by. Manufacturing is the principal industry. Chief among the city's industrial products are: textiles, farm implements, steam boilers, gas, coal and electric stoves and ranges, plumbing supplies, machinery, bathtubs, soil pipe, structural steel, furniture, chemicals, paper, glass bottles, ceramic products, beverages, medicines, cement, candy and electrically treated iron ore. Its educational institutions include: University of Chattanooga (coeducational); two private military schools for boys, Baylor school and McCallie school; one private school for girls, Girls' Preparatory school; and two private grammar-kindergarten schools, Bright school and Wert school; Chattanooga College of Law; Cadek Conservatory of Music; and Tennessee Temple college (Baptist theological).

Signal mountain and Lookout mountain, on the northern and southern outskirts, respectively, of Chattanooga have units of the national military park which offer unusual views of the Tennessee river, Chattanooga and surrounding country. Ascending Lookout mountain is a steep incline railway. Inside Lookout mountain is a cave which contains a natural waterfall 145 ft. high; atop the mountain are unusual rock formations and fine gardens. Lake Chickamauga, a 59-mile-long body of water formed on the Tennessee river by the Chickamauga dam, is a centre for yachting, swimming and fishing. On exhibition in the Union Station is "The General," an old locomotive that was captured by Northern troops in the Civil War and, after a running battle, was recaptured by the Confederates.

A large municipal auditorium, built as a memorial to men of Chattanooga who served in World War I, houses all types of indoor performances.

The beginning of Chattanooga dates from the establishment of a trading post on the Tennessee river by Timothy Meigs and John Ross. Meigs soon died and the trading post, located near what is now downtown Chattanooga, became known as Ross' Landing. In 1834 Ross, who was a Cherokee chief, also built a home about 6 mi. from the landing in what is now Rossville, Ga.; this home is still standing. In 1817 missionaries had established their first mission in the Cherokee nation about 5 mi. east of Ross' Landing and in 1818 the mission was named Brainerd mission in honour of David Brainerd, a missionary among New England Indians. It was incorporated as Chattanooga in 1851, and received a city charter in 1866. In 1911 it adopted a commission form of government. In 1860 the population was 2,545; in 1880, 12,892; in 1900, 30,154. The iron industry was well established even before the development of hydroelectric power, because of the proximity of coal-fields and iron mines. The city and its environs were the scene of important engagements in the Civil War, notably the battles of Chickamauga, on Sept. 19–20, 1863; and of Missionary Ridge and Lookout mountain ("the battle above the clouds"), on Nov. 24–25, 1863. The national cemetery in the city contains 14,248 graves (5,059 marked "unknown"), and there is also a Confederate cemetery. Chickamauga and Chattanooga national military park (8,146.33 ac.) in Tennessee and Georgia was established in 1890. In both the Spanish-American War and World War I it was used for the mobilization and training of troops. Chickamauga battlefield is dotted with more than 2,000 monuments, and many others are scattered over Missionary Ridge, Lookout mountain, Signal mountain and other historic spots. Ft Oglethorpe, just north of the battlefield, is a regimental cavalry post.

Battle of Chattanooga.—From late September to Nov. 24, 1863, the Army of the Cumberland was invested in Chattanooga by the Confederates, whose position lay along Missionary Ridge from its north end toward Rossville, whence their entrenchments extended westward to Lookout mountain, which dominates the whole ground, the Tennessee running directly beneath it. Thus Rosecrans was confined to a semicircle of low ground around Chattanooga itself, and his supplies had to make a long and difficult detour from Bridgeport, the main road being under fire

PLAN OF THE BATTLE OF CHATTANOOGA, NOV. 23–25, 1863

from the Confederate position on Lookout and in the Wauhatchie valley adjacent. Bragg indeed expected that Rosecrans would be starved into retreat. But the Federals once more, and this time on a far larger scale, concentrated in the face of the enemy. The XI and XII corps from Virginia, under Hooker, were transferred by rail to reinforce Rosecrans; other troops were called up from the Mississippi, and on Oct. 16 the Federal government reconstituted the western armies under the supreme command of General Grant. The XV corps of the Army of the Tennessee, under Sherman, was on the march from the Mississippi. Hooker's troops had already arrived when Grant reached Chattanooga on Oct. 23. The Army of the Cumberland was now under Thomas, Rosecrans having been recalled. The first action was fought at Brown's Ferry

in the Wauhatchie valley, where Hooker executed with complete precision a plan for the revictualling of Chattanooga, established himself near Wauhatchie on the 28th, and repulsed a determined attack on the same night. But Sherman was still far distant, and Federal forces at Knoxville, against which a large detachment of Bragg's army under Longstreet was now sent, were in grave danger. Grant waited for Sherman's four divisions, but prepared everything for battle in the meantime. His plan was that Thomas, in the Chattanooga lines, should contain the Confederate centre on Missionary Ridge, while Hooker on the right, at Wauhatchie, was to attack Lookout mountain, and Sherman, farther up the river, was to carry out the decisive attack against Bragg's extreme right wing at the end of Missionary Ridge. The last marches of the XV corps were delayed by stormy weather, Bragg reinforced Longstreet, and telegraphic communication between Grant and the Federals at Knoxville had already ceased. But Grant would not move forward without Sherman, and the battle of Chattanooga was fought more than two months after Chickamauga. On Nov. 23 a forward move of Thomas's army, intended as a demonstration, developed into a serious and successful action, whereby the first line of the Confederate centre was driven in for some distance. Bragg was now much weakened by successive detachments having been sent to Knoxville, and on the 24th the real battle began. Sherman's corps was gradually brought over the river near the mouth of Chickamauga creek and formed up on the east side.

The attack began at 1 P.M. and was locally a complete success. The heights attacked were in Sherman's hands, and fortified against counter-attack, before nightfall. Hooker in the meanwhile had fought the "Battle above the Clouds" on the steep face of Lookout mountain, and though opposed by an equal force of Confederates, had completely driven the enemy from the mountain. The 24th then had been a day of success for the Federals, and the decisive attack of the three armies in concert was to take place on the 25th. But the maps deceived Grant and Sherman as they had previously deceived Rosecrans. Sherman had captured, not the north point of Missionary Ridge, but a detached hill, and a new and more serious action had to be fought for the possession of Tunnel Hill, where Bragg's right now lay strongly entrenched. The Confederates used every effort to hold the position and all Sherman's efforts were made in vain. Hooker, who was moving on Rossville, had not progressed far, and Bragg was still free to reinforce his right. Grant therefore directed Thomas to move forward on the centre to relieve the pressure on Sherman. The Army of the Cumberland was, after all, to strike the decisive blow. About 3.30 P.M. the centre advanced on the Confederate's trenches at the foot of Missionary Ridge. These were carried at the first rush, and the troops were ordered to lie down and await orders. Then occurred one of the most dramatic episodes of the war. Suddenly, and without orders either from Grant or the officers at the front, the whole line of the Army of the Cumberland rose and rushed up the ridge. Two successive lines of entrenchments were carried at once. In a short time the crest was stormed, and after a last attempt at resistance the enemy's centre fled in the wildest confusion. The pursuit was pressed home by the divisional generals, notably by Sheridan. Hooker now advanced in earnest on Rossville, and by nightfall the whole Confederate army, except the troops on Tunnel Hill, was retreating in disorder. These too were withdrawn in the night, and the victory of the Federals was complete. Bragg lost 8,684 men killed, wounded and prisoners out of perhaps 34,000 men engaged; Grant, with 60,000 men, lost about 6,000.

CHATTEL, a term used in English law as equivalent to "personal property," that is, property which, on the death of the owner, devolves on his executor or administrator to be distributed (unless disposed of by will) among the next of kin according to the Statutes of Distributions. Chattels are divided into *chattels real* and *chattels personal*. Chattels real are those interests in land for which no "real action" (*see* PRACTICE AND PROCEDURE) lies; estates which are less than freehold (estates for years, at will, or sufferance) are chattels real. Chattels personal are such things as belong immediately to the person of the owner, and for which if they are injuriously withheld from him, he has no remedy other than by a personal action. Chattels personal are divided into *choses in possession* and *choses in action* (*see* CHOSE).

CHATTEL MORTGAGE, a transaction by which an owner of personal property transfers the property to a creditor for the purpose of securing payment of the debt. The chattel mortgage differs from a pledge in that the latter requires transfer of possession and control of the goods to the creditor, whereas in the typical chattel mortgage full possession and use of the goods remain in the mortgagor. And precisely here lie both the great economic advantage and the social danger of the device. For, having possession, use and control, the mortgagor retains the economic use of goods which he is vastly better able to utilize than is his lender; indeed, out of such use he may realize the wherewithal to pay off the very debt secured by the mortgage. So in the case of a chattel mortgage on crops to be sown or grown, the advances of the country banker are intended to finance the growing of those crops, and will normally be repaid out of its sale. And so with live stock mortgages and mortgages on the equipment of a factory, of a small plant, etc. On the other hand, the continued and unrestricted possession of the goods by the mortgagor is likely to mislead his other creditors, present or prospective, into the belief that his assets are greater than they are; and in the event of trouble, the mortgagee's prior claim, if sustained, may come in to cut them off from any possibility of realizing their debts. Out of this double need has arisen legislation in all American States except Pennsylvania (which does not recognize the chattel mortgage) limiting the validity of the transaction unless the mortgagee takes possession, or unless the mortgage instrument is filed for public information in some prescribed public office. But the details of the legislation are amazingly diverse. In some States the filing is required to be in the county where the mortgagor resides; in others, in that where the goods are located, in still others, in both. In some States possession or filing must occur at once, to be effective; in others, within a fixed period, such as ten days; in still others it is effective as soon as it occurs, whenever that may be. Everywhere, persons purchasing the goods from the mortgagor in possession take free of the mortgage if it has not been filed, and if they are ignorant of it. Everywhere, some of the mortgagor's creditors can disregard the mortgage, if it remains unfiled; but the precise classes of creditors protected vary widely. It may be safely stated, however, that a mortgagee who does not comply with the statute nowhere acquires a satisfactory security.

The requirements of form are equally diverse. The form of apparently outright bill of sale (*q.v.*) is permissible, but not widely used, to evidence chattel mortgages in the United States. In States where no form is required, save a paper signed by the mortgagor, the object is to allow business to be done simply and quickly. But some States attempt to avoid fraudulent practices of mortgagees by requiring the mortgagor to receive, and give a receipt for, a copy of the mortgage; the purpose is to make fraudulent alteration easy to detect. Others fear dishonest practices of mortgagors, and require witnesses or formal acknowledgment to make the document valid. Here the attempt is, in part, to prevent the mortgagor from later denying that he gave the mortgage. Others require, in addition, affidavits by the mortgagor, or by the mortgagee, or by both, that the debt secured is in truth owed, and the transaction *bona fide*. This last requirement arises out of the apparently not uncommon practice of debtors—especially merchants—when approaching insolvency, of creating fictitious debts to their friends, and attempting to divert their assets by colourable mortgages to secure such debts. And because of a similar fear of creditors being misled, a mortgage on a merchant's floating stock in trade has been hedged about by the courts with so many restrictions as to make it worthless as a continuing security to-day. That chattel mortgages are regarded—at least where merchants are the mortgagors—as signs of serious financial difficulty, sufficient to cause suspension of credit, is partly due to this fact, partly to their evil odour because of much attempted fraudulent use, and partly to the fact that in open-credit selling the sellers properly insist on the stock of goods continuing unencumbered: they have supplied the goods; they do not want those same goods to be diverted to paying debts to others.

Almost everywhere a chattel mortgage is good between mortgagor and mortgagee, despite non-compliance with such formalities or with the filing provisions of the local statute. The mortgagee can take possession and foreclose on default in payment of the debt, or in any other of the terms of the transaction—common requirements being that the mortgagor shall keep the goods on the premises, shall not attempt to sell them, nor suffer attachment of the goods by other creditors, and so on. The risk of loss by fire or theft lies, always, on the mortgagor; and often, too, he is required by the mortgage to keep the goods insured for the mortgagee's benefit.

Chattel mortgages are in wide use. Crop mortgages are a major

basis for financing current farm operations throughout the country. The same is true of live stock raising; save that here the mortgages are commonly taken in the first instance by specialized mortgage companies rather than by banks or local merchants. The wide-spread instalment selling business makes considerable use of the device, though more of the conditional sale (*see* INSTALMENT PURCHASE). In the shape of mortgages on articles of personal use such as automobiles and on household furniture, chattel mortgages underlie many of the small consumption loans of needy borrowers—often with serious abuses. And they are becoming increasingly important in corporate mortgage-bond issues, since a mortgage on plant is obviously seriously impaired unless it can be made to cover the plant's equipment as well. In this last field serious discrepancy is beginning to be felt between the real estate portion of the security, as to which recording, once effected, is good forever, and the chattel portion, as to which periodical refiling is necessary. Finally, the chattel mortgage in the peculiar form of the trust receipt is used in the financing of imports, and of the sale of automobiles. In this form—an exception carved by the courts out of general statutes—it is good as against the mortgagor's creditors irrespective of filing or possession; but not as against purchasers without notice.

In the United States the chattel mortgage takes the place of the bill of sale, the latter term being there applied to a signed document describing goods and evidencing their sale, which a seller gives to a buyer who for some reason requires evidence of his ownership. Of late years the prevalence of automobile thefts has led generally to legislation requiring a bill of sale to be made out in the case of sales of second hand cars, and filed with the licensing authorities of the State. (K. N. L.)

See L. A. Jones, *Chattel Mortgages* (Indianapolis, 1908); *Hubbell's Legal Directory* (annual); Karl T. Frederick (1922), *22 Col. L. Rev.*, 395, 546; C. Eliot, *The Farmer's Campaign for Credit* (N.Y., 1927).

CHATTERER, the general name applied to the members of two families of birds. The South American chatterers are the Cotingidae, woodland birds feeding mainly on fruit: the best known are the cocks of the rock, umbrella and bellbirds (*qq.v.*). Chatterer was once inappropriately applied to the waxwing (*q.v.*), originally wrongly placed in a genus of jays, *Garrulus*, which was rendered *chatterer* in an early book on ornithology.

CHATTERIS, urban district and market town in the Isle of Ely, Cambridgeshire, England, 25½ mi. N. by W. of Cambridge by the L.N.E.R. Pop. (1938) 5,085. Area 21 sq.mi. St. Peter's church is principally Decorated. Parts remain of a Benedictine convent founded in the 10th century and rebuilt after fire in the early 14th.

To the north runs the great Forty-foot Drain, also called Vermuyden's, after the Dutch engineer, whose name is associated with the fen drainage works of the mid 17th century.

CHATTERJI, BANKIM CHANDRA (BANKIMACHANDRA CHATTOPADHYAYĀ) (1838–1894). Indian novelist, was born in the district of the Twenty-four Parganas in Bengal on June 27, 1838, and was by caste a Brahman. He was educated at the Hugli college, at the Presidency college in Calcutta, and at Calcutta university, where he was the first to take the degree of B.A. (1858). He entered the Indian civil service, and served as deputy magistrate in various districts of Bengal, his official services being recognized, on his retirement in 1891, by the title of rai bahadur and the C.I.E. He died April 8, 1894. Bankim Chandra was the greatest novelist of India during the 19th century, whether judged by the amount and quality of his writings, or by the influence which they have continued to exercise. He created in India a school of fiction on the European model. His novels include *Durges-Nandini*, *Kapala-Kundala*, *Mrinalini*, and *Bisha-Brikkha*. His outstanding work however is the *Ananda Math*, a story of the Sannyasi rebellion of 1772. The rebels gained a crushing victory over the British and Mohammedan forces. This success was, however, not followed up as a mysterious "physician," speaking as a divinely-inspired prophet, advised Satyananda to abandon further resistance, as, for the time, British rule was the only alternative to Mohammedan oppression. This book contains the famous song *Bande Mataram*.

Although the *Bande Mataram* was not used during Chatterji's life time as a party war-cry, it became, during the agitation which followed the partition of Bengal the recognized patriotic song of the revolutionary party. The words *Bande Mataram*, "Hail to thee Mother" are usually held to be an invocation to Kali the goddess of death and destruction. The Sanyassi rebels are represented as having erected in addition to the dark image of Kali "The Mother who has been" a *white* marble statue of the "Mother that shall be"; the poet sings the praise of the "Mother"

> as Lachmi bowered in the flower
> that in the water grows,

but he also praises her as Durga, bearing "ten weapons." Other passages, too, are susceptible of revolutionary interpretation. Whatever Chatterji's original intention (it is sometimes held that it is merely an invocation of the Motherland) the story of the Sanyassis, the ingenious language and its stirring air, the *Mallar-Kawali Tal*, all have a strong appeal to the Hindu mind and the *Bande Mataram* has become a powerful influence in political agitation and the accepted hymn of the extremist party.

In his earlier years Bankim Chandra served his apprenticeship in literature under Ishwar Chandra Gupta, the chief poet and satirist of Bengal during the earlier half of the 19th century. Bankim Chandra's friend and colleague Dina Bandhu Mitra was virtually the founder of the modern Bengali drama. Among the younger men who venerated Bankim Chandra, and benefited by his example and advice, may be mentioned two distinguished poets, Nabin Chandra Sen and Rabindranath Tagore.

CHATTERTON, THOMAS (1752–1770). English poet, was born at Bristol on Nov. 20, 1752, three months after the death of his father who had been master of the Pile street free school. At Bristol in 1760 Chatterton was sent to the Colston free school where he stayed for eight years. But this ancient blue-coat school had little share in the education of its precocious pupil. The office of sexton at the church St Mary Redcliffe had been held for nearly two centuries by the Chatterton family, and under the guidance of his uncle, the child found his favourite haunt in the beautiful old church, deriving special interest, when he was able to read, in certain quaint old charters where parchment deeds, old as the Wars of the Roses, were heeded and forgotten. In 1763 a beautiful cross of curious workmanship, which had adorned the churchyard of St Mary Redcliffe for upwards of three centuries, was destroyed by a church warden, and the boy sent to the local journal on Jan. 5 a clever satire on the parish vandal. His delight was to shut himself in a little attic, where, with books, cherished parchments saved from the loot of the muniment room of St Mary Redcliffe, and drawing materials he lived in thought with his 15th century heroes and heroines. The first of his literary fabrications, the duologue of "Elinoure and Juga," was written before he was twelve years old, and he showed it to the usher at Colston's hospital, T. Phillips, as the work of a 15th century poet.

His "Rowleian" jargon appears to have been chiefly the result of the study of John Kersey's *Dictionarium Anglo-Britannicum*, and Prof. W. W. Skeat seems to think his knowledge even of Chaucer was very slight. He had already conceived the romance of Thomas Rowley an imaginary monk of the 15th century and lived for the most part in an ideal world of his own, in that elder time when Edward IV. was England's king, and Master William Canynge—familiar to him among the recumbent effigies in Redcliffe church—still ruled in Bristol's civic chair. Canynge is represented as an enlightened patron of literature, and Rowley's dramatic interludes were written for performance at his house. In order to escape a marriage urged by the king, Canynge retired to the college of Westbury in Gloucestershire, where he enjoyed the society of Rowley, and eventually became dean of the institution. The literary masquerade which thus constituted the life-dream of the boy was wrought out by him in fragments of prose and verse into a coherent romance, until the credulous scholars and antiquaries of his day were persuaded into the belief that there had lain in the parish chest of Redcliffe church for upwards of three centuries, a collection of mss. of rare merit, the work of Thomas Rowley, an unknown priest of Bristol in the days

of Henry VI., and his poet laureate, John Lydgate.

Among the Bristol patrons of Chatterton were two pewterers: George Catcott and his partner Henry Burgum. Catcott was one of the most zealous believers in Rowley, and continued to collect his reputed writings long after the death of their real author. On Burgum, who had risen in life by his own exertions, the blue-coat boy palmed off the de Bergham pedigree, and other equally apocryphal evidences of the pewterer's descent from an ancestry old as the Norman Conquest. The de Bergham quartering, blazoned on a piece of parchment doubtless recovered from the Redcliffe muniment chest, was itself supposed to have lain for centuries in that ancient depository. The pedigree was professedly collected by Chatterton from original records, including "The Rowley mss." The pedigree still exists in Chatterton's own handwriting, copied into a book in which he had previously transcribed portions of antique verse, under the title of "Poems by Thomas Rowley, priest of St. John's, in the city of Bristol"; and in one of these, "The Tournament," Syrr Johan de Berghamme plays a conspicuous part. The ennobled pewterer rewarded Chatterton with five shillings, and was satirized for the exhibition of a noble pedigree in some of Chatterton's latest verse.

On July 1, 1767, Chatterton was transferred to the office of John Lambert, attorney, to whom he was bound apprentice as a clerk. There he found leisure for his own favourite pursuits. An ancient stone bridge on the Avon, built in the reign of Henry II., had been displaced by a new bridge opened in 1768. Shortly afterwards the editor of *Felix Farley's Journal* received from a correspondent signing himself *Dunelmus Bristoliensis*, a "description of the mayor's first passing over the old bridge," professedly derived from an ancient ms. The original manuscript is now preserved in the British Museum, along with other Chatterton mss., most of which were ultimately incorporated by William Barrett in his *History and Antiquities of the city of Bristol*, published nearly 30 years after the poet's death. It was at this time that the definite story made its appearance—over which critics and antiquaries wrangled for nearly a century—of numerous ancient poems and other mss. taken by the elder Chatterton from a coffer in the muniment room of Redcliffe church and transcribed, and so rescued from oblivion, by his son. The pieces include the "Bristowe Tragedie or the Dethe of Syr Charles Bawdin," a ballad celebrating the death of the Lancastrian knight, Charles Baldwin; "Ella," a "Tragycal Enterlude" as Chatterton styles it, but in reality a dramatic poem of sustained power; "Goddwyn," a dramatic fragment; "Tournament," "Battle of Hastings," "The Parliament of Sprites," "Balade of Charitie," with numerous shorter pieces, forming altogether a volume of poetry, the rare merit of which is indisputable wholly apart from the fact that it was the production of a mere boy.

In Dec. 1768, in his seventeenth year, he wrote to Dodsley, the London publisher, offering to procure for him "copies of several ancient poems, and an interlude, perhaps the oldest dramatic piece extant, wrote by one Rowley, a priest in Bristol, who lived in the reigns of Henry VI. and Edward IV." To this letter as well as to another letter enclosing an extract from the tragedy of "Ella," no answer appears to have been returned. Chatterton then bethought him of Horace Walpole, who not only indulged in a mediaeval renaissance of his own, but was the reputed author of a spurious antique in the *Castle of Otranto*. He wrote to him offering him a document entitled "The Ryse of Peyncteyne yn Englande, wroten by T. Rowleie, 1469, for Mastr Canynge," accompanied by notes which included specimens of Rowley's poetry. To this Walpole replied with courteous acknowledgments. He characterized the verses as "wonderful for their harmony and spirit," and added, "Give me leave to ask you where Rowley's poems are to be had? I should not be sorry to print them, or at least a specimen of them, if they have never been printed." Chatterton replied, enclosing additional specimens of antique verse, and telling Walpole that he was the son of a poor widow, and clerk to an attorney, and he hinted a wish that he might help him to some more congenial occupation. Walpole's manner underwent an abrupt change. The specimens of verse had been submitted to his friends, Gray and Mason, and pronounced modern. He now coldly advised the boy to stick to the attorney's office, and "when he should have made a fortune," he might betake himself to more favourite studies. Chatterton had to write three times before he recovered his mss. Walpole has been loaded with more than his just share of responsibility for the fate of the unhappy poet, of whom he admitted when too late, "I do not believe there ever existed so masterly a genius."

Chatterton now began to contribute to the *Town and County Magazine* and other London periodicals. Assuming the vein of Junius—then in the full blaze of his triumph—he turned his pen against the duke of Grafton, the earl of Bute, and the princess of Wales. He had just despatched one of his political diatribes to the *Middlesex Journal*, when he sat down on Easter Eve, April 17, 1770, and penned his "Last Will and Testament," a strange satirical compound of jest and earnest, in which he intimated his intention of putting an end to his life the following evening. Among his satirical bequests, such as his "humility" to the Rev. Mr. Camplin, his "religion" to Dean Barton, and his "modesty" along with his "prosody and grammar" to Mr. Burgum, he leaves "to Bristol all his spirit and disinterestedness, parcels of goods unknown on its quay since the days of Canynge and Rowley." In more genuine earnestness he recalls the name of Michael Clayfield, a friend to whom he owed intelligent sympathy. The will was probably purposely prepared in order to frighten his master into letting him go. Lambert cancelled his indentures, his friends made him up a purse, and on the 25th or 26th of the month he arrived in London.

Chatterton was already known to the readers of the *Middlesex Journal* as a rival of Junius under the *nom de plume* of Decimus. He had also been a contributor to Hamilton's *Town and County Magazine*, and speedily found access to the *Freeholder's Magazine*, another political miscellany strong for Wilkes and liberty. Wilkes himself had noted his trenchant style, "and expressed a desire to know the author"; and Lord Mayor Beckford graciously acknowledged a political address of his, and greeted him "as politely as a citizen could." But of actual money he received little. He was extremely abstemious, but his diligence was great, and his versatility wonderful. He could assume the style of Junius or Smollett, reproduce the satiric bitterness of Churchhill, parody Macpherson's Ossian, or write in the manner of Pope, or with the polished grace of Gray and Collins. He wrote political letters, eclogues, lyrics, operas and satires, both in prose and verse. In June, 1770—after Chatterton had been some nine weeks in London—he removed from Shoreditch, where he had hitherto lodged with a relative, to an attic in Brook street, Holborn, where, for the first time, he enjoyed uninterrupted solitude. The romance of his earlier years revived, and he transcribed from an imaginary parchment of the old priest Rowley his "Excelente Balade of Charitie." This fine poem, perversely disguised in archaic language, he sent to the editor of the *Town and County Magazine*, and had it rejected.

The high hopes of the sanguine boy had begun to fade. He had not yet completed his second month in London, and already failure and starvation stared him in the face. The note of his actual receipts, found in his pocket-book after his death, shows that Hamilton, Fell and other editors who had been so liberal in flattery had paid him at the rate of a shilling for an article, and somewhat less than eightpence each for his songs; while much which had been accepted was held in reserve, and still unpaid for. The beginning of a new month revealed to him the indefinite postponement of the publication and payment of his work. He had wished, according to his foster-mother, to study medicine with Barrett; in his desperation he now reverted to this, and wrote to Barrett for a letter to help him to an opening as a surgeon's assistant on board an African trader. He appealed also to Mr. Catcott to forward his plan, but in vain. On Aug. 24, 1770, he retired for the last time to his attic in Brook street, carrying with him the arsenic which he there drank, after tearing into fragments whatever literary remains were at hand.

He was only seventeen years and nine months old; but the best of his numerous productions, both in prose and verse, require no allowance to be made for the immature years of their author. He pictures Lydgate, the monk of Bury St. Edmund's, challenging Rowley to a trial at versemaking, and under cover of this fiction, produces his "Songe of Ælla," a piece of rare lyrical beauty, worthy of comparison with any antique or modern production of its class. Again, in his "Tragedy of Goddwyn," of which only a fragment has been preserved, the "Ode to Liberty," with which it abruptly closes, may claim a place among the finest martial lyrics in the language. The death of Chatterton attracted little notice at the time; for the few who then entertained any appreciative estimate of the Rowley poems regarded him as their mere transcriber. He was interred in a burying-ground attached to Shoe Lane Workhouse. A monument has since been erected to his memory in Redcliffe churchyard, Bristol, with the appropriate inscription, borrowed from his "Will," and so supplied by the poet's own pen—"To the memory of Thomas Chatterton. Reader! judge not. If thou art a Christian, believe that he shall be judged by a Superior Power. To that Power only is he now answerable."

BIBLIOGRAPHY.—*Poems supposed to have been written at Bristol by Thomas Rowley and others, in the Fifteenth Century* (1777) was edited by Thomas Tyrwhitt; Thomas Warton, in his *History of English Poetry* (1778); vol. ii., section viii., gives Rowley a place among the 15th century poets; but neither of these critics believed in the antiquity of the poems. In 1782 a new edition of Rowley's poems appeared, with a "Commentary, in which the antiquity of them is considered and defended," by Jeremiah Milles, dean of Exeter. The controversy which raged round the Rowley poems is discussed in A. Kippis *Biographia Britannica* (vol. iv., 1789), where there is a detailed account by G. Gregory of Chatterton's life (pp. 573–619). This was reprinted in the edition (1803) of Chatterton's *Works* by R. Southey and J. Cottle, published for the benefit of the poet's sister. The neglected condition of the study of earlier English in the 18th century alone accounts for the temporary success of Chatterton's mystification. It has long been agreed that Chatterton was solely responsible for the Rowley Poems, but the language and style are analysed in confirmation of this view by Prof. W. W. Skeat in an introductory essay prefaced to vol. ii. of *The Poetical Works of Thomas Chatterton* (1871) in the "Aldine Edition of the British Poets." This, which is the most convenient edition, also contains a memoir of the poet by Edward Bell. The spelling of the Rowley poems is there modernized, and many of the archaic words are replaced by modern equivalents provided in many cases from Chatterton's own notes, the theory being that Chatterton usually composed in modern English, and inserted his peculiar words and his complicated orthography afterwards. *See* also H. B. Forman, *Thomas Chatterton and his latest Editor* (1874). The Chatterton mss., originally in the possession of William Barrett of Bristol, were left by his heir to the British Museum in 1800. Others are preserved in the Bristol library.

Chatterton's genius and his tragic death are commemorated by Shelley in *Adonais*, by Wordsworth in "Resolution and Independence," by Coleridge in "A Monody on the Death of Chatterton," by D. G. Rossetti in "Five English Poets"; John Keats inscribed *Endymion* "to the memory of Thomas Chatterton." Alfred de Vigny's drama of *Chatterton* gives an altogether fictitious account of the poet. Sir Herbert Croft, in his *Love and Madness*, interpolated a long and valuable account of Chatterton, giving many of the poet's letters, and much information obtained from his family and friends (pp. 125–244, letter li.). There is a valuable collection of "Chattertoniana" in the British Museum, consisting of separate works by Chatterton, newspaper cuttings, articles, dealing with the Rowley controversy and other subjects, with ms. notes by Joseph Haslewood, and several autograph letters. F. A. Hyatt and W. Bazeley, *Chattertoniana* (Gloucester, 1914), a catalogue of printed matter.

Among biographies of Chatterton may be mentioned Daniel Wilson, *Chatterton: A Biographical Study* (1869); D. Masson, *Chatterton: A Biography* (1899); Helene Richter, "Thomas Chatterton" (1900), in *Wiener Beitrage zur engl. Philologie;* C. E. Russell, *Chatterton*, (1900); J. H. Ingram, *The True Chatterton* (1910); Sir E. Clarke, *New Lights on Chatterton* (1916), a paper read before the Bibliographical Society, London.

CHATTI, an ancient German tribe inhabiting the upper reaches of the rivers Weser, Eder, Fulda and Werra, a district approximately corresponding to Hesse-Cassel, though probably somewhat more extensive. They frequently came into conflict with the Romans during the early years of the 1st century A.D. Eventually they formed a portion of the Franks and were incorporated in the kingdom of Clovis at the beginning of the 6th century.

See Tacitus, *Annals*, i., ii., xi., xii. and xiii.; *Germania*, 30–31.

CHAUCER, GEOFFREY (1340?–1400), English poet, was born, about 1340, of a family which had been settled in London for at least two generations, but probably came from the eastern counties. His father, John Chaucer, lived at one time in Cordwainer street, the quarter of the shoemakers, with which the name Chaucer (a French form of the Latin *Calcearius*) connects the family. But John Chaucer, his father Robert, and a stepfather Richard, were vintners, and Robert and John held offices connected with the customs on wine. Geoffrey was probably born at Thames street, where his father is found living somewhat later, with a wife, Agnes, niece of Hamo de Compton, probably the poet's mother. In 1357 Geoffrey is found, apparently as a lad, in the service of Elizabeth, countess of Ulster, wife of Lionel duke of Clarence. In 1359 he went to the war in France and is heard of at Retters, *i.e.*, Rethel, near Reims, and as being taken prisoner. The king contributed £16 to his ransom and it is probable that after his return he was for some time at the Inner Temple, where, at a considerable cost, an education was given likely to help suitable men for civil employment under the Crown. By June 20, 1367, he had been long enough in the king's service to be granted a pension of 20 marks, probably in connection with his marriage with a Philippa, one of two daughters of Sir Payne Roet, who in the previous September had been granted a pension of ten marks for her services to the queen as one of her *domicellae*. Philippa's sister, Katherine, after the death of her husband, Sir Hugh de Swynford, in 1372, became governess to John of Gaunt's children, and subsequently his mistress, and (in 1396) his wife. The marriage with Philippa thus helps to account for the favour subsequently shown to Chaucer by John of Gaunt.

In the grant of his pension Chaucer is called "dilectus valletus noster," our beloved yeoman; before the end of 1368 he had risen to one of the king's esquires. In September of the following year John of Gaunt's wife, the duchess Blanche, died at the age of 29, and Chaucer wrote in her honour *The Book of the Duchesse*, a poem of 1,334 lines in octosyllabic couplets. In June 1370 he went abroad on the king's service, on an unknown errand, returning probably some time before Michaelmas. On Dec. 1, 137-, he started, with an advance of 100 marks in his pocket, for Italy, as one of three commissioners to treat with the Genoese as to an English port where they might have special facilities for trade. His accounts, delivered on May 23, 1373, show that he had also visited Florence on the king's business, and he possibly went also to Padua and there made the acquaintance of Petrarch.

In the second quarter of 1374, Chaucer lived in a whirl of prosperity. On April 23 the king granted him a pitcher of wine daily, subsequently commuted for an annuity of 20 marks. From John of Gaunt, who in Aug. 1372 had granted Philippa Chaucer £10 a year, he himself now received (June 13) a like annuity. On June 8 he was appointed (with a salary of £10 and an annual gratuity of £6 13s.4d.) comptroller of the Custom and Subsidy of Wools, Hides and Woodfells and also of the Petty Customs of Wine in the Port of London. Probably in anticipation of this appointment he had taken, on May 10, a lease for life from the city of London of the dwelling-house above the gate of Aldgate, and here he lived for the next 12 years. In 1375–76 two large windfalls came to him, the first being two wardships of Kentish heirs, one of whom paid him £104, the second a grant of £71 4s.6d. the value of some confiscated wool. In Dec. 1376 he was sent abroad on the king's service in the retinue of Sir John Burley; in Feb. 1377 he was sent to Paris and Montreuil in connection probably with the peace negotiations between England and France, and at the end of April (after a reward of £20 for his good services) he was again despatched to France. It is generally considered that this diplomatic period of his life was unprolific in poetry.

On the accession of Richard II., Chaucer was confirmed in his offices and pensions. In Jan. 1378 he seems to have been in France in connection with a proposed marriage between Richard and the daughter of the French king; and on May 28 of the same year he was sent (his last diplomatic journey) with Sir Edward de Berkeley to the lord of Milan and Sir John Hawkwood to treat for help in the king's wars, returning on Sept. 19. In April 1382 a new comptrollership, that of the petty customs in the Port of London,

was given him, and shortly after he was allowed to exercise it by deputy, a similar licence being given him in Feb. 1385, at the instance of the earl of Oxford, as regards the comptrollership of wool. In Oct. 1385 he was made a justice of the peace for Kent. In Feb. 1386 we catch a glimpse of his wife, Philippa, being admitted to the fraternity of Lincoln cathedral in the company of Henry, earl of Derby (afterwards Henry IV.), Sir Thomas de Swynford and other distinguished persons. In Aug. 1386 he was elected one of the two knights of the shire for Kent, and with this dignity (one not much appreciated in those days) his good fortune reached its climax. In December he was superseded in both his comptrollerships, probably as a result of the absence of his patron, John of Gaunt, in Spain, and the supremacy of the duke of Gloucester. In the following year the cessation of Philippa's pension suggests that she died between midsummer and Michaelmas. In May 1388 Chaucer surrendered to the king his two pensions of 20 marks each, and they were regranted at his request to one John Scalby, an unusual transaction, pointing to a pressing need for ready money.

In July 1389, after John of Gaunt had returned to England, and the king had taken the government into his own hands, Chaucer was appointed clerk of works at various royal palaces at a salary of two shillings a day. To this post was subsequently added the charge of some repairs at St. George's chapel, Windsor. He was also made a commissioner to maintain the banks of the Thames between Woolwich and Greenwich, and was given by the earl of March (grandson of Lionel, duke of Clarence, his first patron) a sub-forestership at North Petherton, Devon; obviously a sinecure. While on the king's business, in Sept. 1390, Chaucer was twice robbed by highwaymen, losing £20 of the king's money. In June 1391 he was superseded as clerk of the works, and seems to have suffered another spell of misfortune, of which the first alleviation came in Jan. 1393, when the king made him a gift of £10. In Feb. 1394 he was granted a new pension of £20. In 1397 he received from King Richard a grant of a butt of wine yearly. For this he appears to have asked in terms that suggested poverty, and in May 1398 he obtained letters of protection against his creditors. On the accession of Henry IV. a new pension of 40 marks was granted him (Oct. 13, 1399) and Richard II.'s grants were formally confirmed. Though no instalment of the new pension was paid, on the strength of his expectations (Dec. 24, 1399) Chaucer leased a tenement in the garden of St. Mary's chapel, Westminster, and it was probably here that he died on the following Oct. 25. He was buried in Westminster Abbey, and his tomb became the nucleus of what is now known as Poets' Corner. The portrait of Chaucer, which the affection of his disciple, Thomas Hoccleve, caused to be painted in a copy of the latter's *Regement of Princes* (now Harleian ms. 4.866 in the British Museum), shows him an old man with white hair; he has a fresh complexion, grey eyes, a straight nose, a grey moustache and a full double-pointed beard. His dress and hood are black, and he carries in his hands a string of beads.

Works.—Henry IV.'s promise of an additional pension was doubtless elicited by the *Compleynt to his Purs*, in the envoy to which Chaucer addresses him as the "conquerour of Brutes Albion" Thus within the last year of his life the poet was still writing. Nevertheless, as early as 1393–94, in lines to his friend Vogan, he had written as if his day for poetry were past, and it seems probable that his longer poems were all composed before this date. In the preceding 15—or, if another view be taken, 20—years, his literary activity was very great, and with the aid of the lists of his works which he gives in the *Legende of Good Women* (lines 414–431), and the talk on the road which precedes the "Man of Lawe's Tale" (*Canterbury Tales*, B. 46–76), the order in which his main works were written can be traced with approximate certainty.

The development of Chaucer's genius has been attractively summed up as comprised in three stages, French, Italian and English, and there is a rough approximation to the truth in this formula, since his earliest poems are translated from the French or based on French models, and the two great works of his middle period are borrowed from the Italian, while his latest stories have no such obvious and direct originals, and in their humour and freedom anticipate the typically English temper of Henry Fielding. But Chaucer's indebtedness to French poetry was no passing phase. He knew the *Roman de la rose* as modern English poets know Shakespeare, and the full extent of his debt to his French contemporaries, not merely in 1369, but in 1385, and in 1393 (the dates are approximate), has only gradually been discovered. To this continuing French influence it was his good fortune to add lessons in plot and construction derived from Boccaccio's *Filostrato* and *Teseide*, as well as some glimpses of the higher art of the *Divina Commedia*. He shows acquaintance also with one of Petrarch's sonnets. His study of Italian models was thus an episode of unique importance in his literary life, but before it began he had already been making his own artistic experiments, and it is noteworthy that while he learnt much from Boccaccio he improved on his originals as he translated them. Doubtless his busy life in the service of the Crown had taught him self-confidence, and he uses his Italian models in his own way and with the most triumphant and assured success. When he had no more Italian poems to adapt he had learnt his lesson. In his "English" period we find him taking what might be little more than an anecdote and lending it body and life and colour with a skill never surpassed.

Early Period.—The most direct example of Chaucer's French studies is his translation of *Le Roman de la rose*, a poem written in some 4,000 lines by Guillaume de Lorris about 1237 and extended to over 22,000 by Jean Clopinel, better known as Jean de Meun, 40 years later. We know from Chaucer himself that he translated this poem, and the extant English fragment of 7,698 lines was generally assigned to him from 1532, when it was first printed, till its authorship was challenged in the early years of the Chaucer Society. The ground of this challenge was its wide divergence from Chaucer's practice in his undoubtedly genuine works as to certain niceties of rhyme, notable as to not rhyming words ending in *-y* with others ending *-ye*. It was subsequently contended, however, that the whole fragment is divisible linguistically into three portions, of which the first and second end respectively at lines 1,705 and 5,810, and that in the first of these three sections the variations from Chaucer's accepted practice are insignificant. Lines 1–1,705 have therefore been provisionally accepted as Chaucer's and the other two fragments as the work of unknown translators which somehow came to be pieced together. A rival theory proposed by Dr. Brusendorf assigns the whole fragment to a professional reciter writing down what he remembered of the parts of Chaucer's translation he was accustomed to recite, and varying when his memory failed.

While our knowledge of Chaucer's *Romaunt of the Rose* is in this unsatisfactory state, another translation of his from the French, the *Book of the Lyon* (alluded to in the "Retraction" found, in some manuscripts, at the end of the *Canterbury Tales*), which must certainly have been taken from Guillaume Michault's *Le Dit du lion*, has perished altogether. The strength of French influence on Chaucer's early work may, however, be amply illustrated from the first of his poems with which we are on sure ground, the *Book of the Duchesse*, or, as it is alternatively called, the *Deth of Blaunche*. Here not only are individual passages closely imitated from Machault and Froissart, but the dream, the May morning, and the whole machinery of the poem are taken over from contemporary French conventions. But even at this stage, Chaucer could prove his right to borrow by the skill with which he makes his materials serve his own purpose, and some of the lines in the *Deth of Blaunche* are among the most tender and charming he ever wrote.

Chaucer's *A.B.C.*, a poem in honour of the Blessed Virgin, of which the stanzas begin with the successive letters of the alphabet, is another example of French influence. It is taken from the *Pèlerinage de la vie humaine*, written by Guillaume de Deguilleville about 1330. The occurrence of some magnificent lines in Chaucer's version, combined with evidence that he did not yet possess the skill to translate at all literally as soon as rhymes had to be considered, accounts for this poem having been dated sometimes earlier than the *Book of the Duchesse*, and sometimes sev-

eral years later. With it is usually moved up and down, though it should surely be placed in the '70s, the *Compleynt to Pity*, a fine poem which yet, from its slight obscurity and absence of Chaucer's usual ease, may very well some day prove to be a translation from the French.

Middle Period.—While Chaucer thus sought to reproduce both the matter and the style of French poetry in England, he found other materials in popular Latin books. Among his lost works are renderings of "Origenes upon the Maudeleyne" and of Pope Innocent III. on "The Wrecched Engendring of Mankinde" (*De miseria conditionis humanae*). He must have begun his attempts at straightforward narrative with the *Lyf of Seynt Cecyle* (the weakest of all his works, the second Nun's Tale in the Canterbury series) from the *Legenda Aurea* of Jacobus de Voragine and the story of the patience of Grisilde taken from Petrarch's Latin version of a tale by Boccaccio. In both of these he condenses a little, but ventures on very few changes, though he lets his readers see his impatience with his originals. In his story of Constance (afterwards ascribed to the Man of Lawe), taken from the Anglo-Norman chronicle of Nicholas Trivet, written about 1334, we find him strengthening another weak tale, but still without the courage to remedy its radical faults, though here, as with Grisilde, he does as much for his heroine as the conventional exaltation of one virtue at a time permitted. It is possible that other tales which now stand in the Canterbury series were written originally at this period. What is certain is that at some time in the '70s, independently of any glimpses he may have obtained of the *Divina Commedia* and of Petrarch's sonnets, two notable Italian poems by Boccaccio passed into Chaucer's possession and that the turning of the *Filostrato* into *Troilus and Criseyde* and the *Teseide* into "al the storye of Palamon and Arcyte" was his main poetic business during the next few years and vitally affected his development. He did not, however, work on these masterpieces uninterruptedly. Almost at the outset two court poems had to be written in connection with the betrothal and marriage of Richard II. to Anne of Bohemia, the *Hous of Fame* and *The Parlement of Foules*. The former begins with a dream on a certain tenth of December and Dr. Aage Brusendorf is almost certainly right in linking this with the formal appointment on Dec. 12, 1380, of an English embassy to treat for the marriage and the conception of the poem with Froissart's *Le Temple d'Honneur* in which a marriage is guardedly forecast. Unhappily, one or more leaves at the end of the archetype manuscript of Chaucer's poem were lost before other copies were made from it, so that the conjecture cannot be finally verified, but it offers a much needed clue to the meaning, which had previously been rashly connected with Dante's *Divina Commedia*. Written in octosyllabic couplets, like the *Romaunt of the Rose*, it shows Chaucer already possessed of the conversational ease which marks his later work, but the ease tempted him to extend the poem to a length out of keeping with his subject, and it is best known by the few lines in which he talks about himself. *The Parlement of Foules*, written in seven-line stanzas, commemorating the delay of over a year in the celebration of the marriage, and full of gaiety and humour, is in much better proportion.

Besides these two poems Chaucer about this time produced his most important prose work, the translation of the *De Consolatione Philosophiae* of Boethius. Reminiscences of this helped to enrich many of his subsequent poems and inspired five of his shorter pieces (*The Former Age, Fortune, Truth, Gentilesse* and *Lak of Stidfastnesse*), but the translation itself cannot be counted a success. To borrow Chaucer's own phrase his "English was insufficient" to reproduce such difficult Latin. The translation is often barely intelligible without the original, and it is only here and there that it flows with any ease or rhythm.

Troilus and Criseyde.—A snatch of abuse of his scrivener shows that the translation of Boethius and *Troilus and Criseyde* were being copied for circulation at the same time and in the *Troilus*, after a good many half-successes, Chaucer achieved a great artistic triumph. He follows Boccaccio's *Filostrato* step by step, but he does not follow it as a mere translator. He had done his duty manfully for St. Cecyle, Grisilde and Constance, whom he was forbidden by the conventions of his originals to clothe with complete flesh and blood. In this great story of love and betrayal there were no such restrictions and the characters, which Boccaccio's treatment left thin and conventional, became in Chaucer's hands convincingly human. No other English poem is so instinct with the glory and tragedy of youth, and in the details of the story Chaucer's gifts of vivid colouring, of humour and pity, are all at their highest. *Troilus and Criseyde* is written in seven line stanzas for the telling from the *Teseide* the story of *Palamon and Arcyte*. Chaucer used for the first time decasyllabic couplets for which Guillaume Machault had provided him with a French model, with a great gain in swiftness and compression. The story has not the poignant interest of the *Troilus* or probably the "comedye" which in the epilogue to the earlier poems Chaucer promised to write, but Chaucer's skill is again at its highest. This time, while he takes Boccaccio's plot, he takes only as much of it as he wants and what he takes he heightens and humanizes with the same skill as he had shown in transforming the *Filostrato*. Of the individual characters Theseus himself, the arbiter of the story, is developed a, notably as Sir Pandarus in the *Troilus*, while the fair Emilye and her two lovers-at-first-sight receive just as much individuality as they can be given without burdening the story with a greater intensity than it will bear. With what revision we know not, the story was fitted into the *Canterbury Tales* and assigned to the chivalrous Knight; but that it was written soon after *Troilus* and the translation of Boethius and before the *Legende of Good Women* (in which it is mentioned), should not be doubted, though other theories have been proposed.

When the *Teseide* had been used, Chaucer had no more Italian stories to translate and he turned to his Latin materials to compile a lectionary of Cupid's Saints for presentation to the queen. To atone for his portrayal of the disloyalty of Criseyde he accepted as a penance the painting of 19 women faithful to love, with Alcestis as their queen, enriching his scheme with a delightful prologue (extant in two rather widely differing forms) into which he introduces touches about his worship of the Deity and the controversy between the partisans of the Flower and the Leaf from his French friends, Froissart and Deschamps. Of the stories of constant women, those of Dido and Cleopatra are fully worthy of him. When, however, he had written eight and part of a ninth he wearied of the monotony of his theme, which he was beginning to treat with scant respect, and broke off.

Canterbury Tales.—Chaucer's failure to complete the scheme of the *Legende of Good Women* may have been partly due to the attractions of the *Canterbury Tales*, which were probably taken up in immediate succession to it. His guardianship of two Kentish wards, his justiceship of the peace, his representing the county in the parliament of 1386, his commissionership of the river-bank between Greenwich and Woolwich, all make it easy to understand his dramatic use of the merry crowds he saw on the Canterbury road, without supposing him to have had recourse to Boccaccio's *Decameron*, a book which there is no proof of his having seen. The pilgrims whom he imagines to have assembled at the Tabard inn in Southwark, where Harry Bailey was host, are said to have numbered "wel nyne and twenty in a company," and the Prologue gives full-length sketches (at least some of which Prof. Manly, in his *New Light on Chaucer*, has shown to have been drawn from life) of a Knight, a Squire (his son), and their Yeoman; of a Prioress, Monk, Friar, Oxford Clerk, and Parson, with two disreputable hangers-on of the church, a Summoner, and a Pardoner; of a Serjeant-at-Law and a Doctor of Physic, and of a Franklin, or country gentleman, Merchant, Shipman, Miller, Cook, Manciple, Reeve, Ploughman (the Parson's brother) and the ever-famous Wife of Bath. Five London burgesses are described in a group, and a Nun and Priest (altered possibly in a moment of hopefulness by Chaucer himself, to "priestes three") are mentioned as in attendance on the Prioress. Each of these, with Chaucer himself making the 29th, was pledged to tell two tales, but including one second attempt and a tale told by the Yeoman of a Canon, who overtakes the pilgrims on the road, we have only 20 finished stories, two unfinished and two interrupted ones.

As in the case of the *Legende of Good Women*, our loss is not so much that of the additional stories as of the completed framework. The wonderful character sketches of the Prologue are carried yet farther by the Talks on the Road which link the different tales, and two of these Talks, in which the Wife of Bath and the Pardoner respectively edify the company, have the importance of separate Tales, but between the Tales that have come down to us there are seven links missing, and it was left to a later and weaker hand to narrate, in the "Tale of Beryn," the adventures of the pilgrims at Canterbury.

The reference to the *Lyf of Seynt Cecyle* in the prologue to the *Legende of Good Women* gives external proof that Chaucer included earlier work in the scheme of the *Canterbury Tales*, and mention has been made of other stories which are indisputably early, while in the case of at least two, the Clerk's tale of Grisilde and the Monk's tragedies, there is evidence of early work being revised and supplemented. It is fortunately impossible to separate the prologue to the charmingly told story of "yonge Hugh of Lincoln" from the tale itself, and with the "quod sche" in the second line as proof that Chaucer was here writing specially for his pilgrims we are forbidden to limit the new stories to any one period or tone. There can be no doubt however, that what may be called the Tales of the Churls (Miller, Reeve, Summoner, Friar, etc.), and the conversational outpourings of the Pardoner and Wife of Bath, form, with the immortal Prologue, the most important and distinctive additions to the older work. In these, and in the Pardoner's story of Death and the Three Revellers, and the Nun's Priest's masterly handling of the fable of the Cock and Fox, both of them free from the grossness which marks the others, Chaucer takes stories which could have been told in a short page of prose and elaborates them with all the skill in narration which he had sedulously cultivated. The conjugal reminiscences of the Wife of Bath and the Reeve's Tale with its abominable climax (lightened a little by Aleyn's farewell, lines 4299–4319) are among the great things in Chaucer, as surely as *Troilus* and *Palamon and Arcyte* and the *Prologue*. They help notably to give him the width of range which may certainly be claimed for him.

In or soon after 1391 Chaucer wrote in prose for an 11-year-old reader, whom he addresses as "Litel Lowis my son," a treatise of the use of the Astrolabe, its short prologue being the prettiest specimen of his prose. The wearisome tale of "Melibee and his wyf Prudence," which was perhaps as much admired in English as it had been in Latin and French, may have been translated at any time. The sermon on Penitence, used as the Parson's Tale, was probably the work of his old age. "Envoys" to his friends Scogan and Bukton, a translation of some balades by Sir Otes de Granson and the *Complaynt to his Purs* complete the record of his minor poetry. We have his own statement that in his youth he had written many Balades, Roundels and Virelayes in honour of Love, and the two songs embedded respectively in the *Parlement of foules* and the Prologue to the *Legende of Good Women* are charming and musical. His extant shorter poems, however, whether early or late, offer no excuse for claiming high rank for him as a lyrist. He had very little sheer singing power, and though there are fine lines in his short poems, witness the famous "Flee fro the prees and dwell with soothfastnesse," they lack the sustained concentration of great work. From the drama, again, Chaucer was cut off, and it is idle to argue from the innumerable dramatic touches in his poems and his gift of characterization as to what he might have done had he lived two centuries later. His own age delighted in stories, and he gave it the stories it demanded invested with a humanity, a grace and strength which place him among the world's greatest narrative poets, and which bring the England of his own day, with all the colour and warmth of life, wonderfully near to his readers.

The part played by Chaucer in the development of the English language has often been overrated. He neither corrupted it, as used to be said, by introducing French words which it would otherwise have avoided, nor bore any such part in fixing it as was afterwards played by the translators of the Bible. The practical identity of Chaucer's language with that of Gower shows that both merely used the best English of their day with the care and slightly conservative tendency which befitted poets. Chaucer's service to the English language lies in his decisive success having made it impossible for any later English poet to attain fame, as Gower had done, by writing alternatively in Latin and French.

Chaucer borrowed both his stanza forms and his "decasyllabic" couplet (mostly with an extra syllable at the end of the line) from Guillaume Machault, and his music, like that of his French master and his successors, depends very largely on assigning to every syllable its full value and more especially on the due pronunciation of the final *-e*. The slower movement of change in Scotland allowed time for Chaucer to exercise a potent influence on Scottish poetry but in England this final *-e*, to which most of the earlier grammatical forms by Chaucer's time had been reduced, itself fell rapidly into disuse during the 15th century. his disciples, Hoccleve and Lidgate, quickly lost touch with his rhythms and successive copyists reduced his text to a state in which it was only by accident that lines could be scanned correctly. For fully three centuries his reputation was sustained solely by his narrative power, his warmest panegyrists betraying no consciousness that they were praising one of the greatest technical masters of poetry. Even when thus maimed, however, his works found readers and lovers in every generation, and every improvement in his text has set his fame on a surer basis.

BIBLIOGRAPHY.—The *Canterbury Tales* have always been Chaucer's most popular work, and, including fragments, upwards of 60 15th century manuscripts of it still survive. Two thin volumes of his minor poems were among the little quartos which Caxton printed by way of advertisement immediately on his return to England; the *Canterbury Tales* and *Boethius* followed in 1478, *Troilus* and a second edition of the *Tales* in 1483, the *Hous of Fame* in 1484. The *Canterbury Tales* were subsequently printed in 1492 (Pynson), 1498 (de Worde) and 1526 (Pynson); *Troilus* in 1517 (de Worde) and 1526 (Pynson); the *Hous of Fame* in 1526 (Pynson); the *Parlement of Foules* in 1526 (Pynson) and 1530 (de Worde), and the *Mars*, *Venus* and *Envoy to Bukton* by Julyan Notary about 1500. Pynson's three issues in 1526 almost amounted to a collected edition, but the first to which the title *The Workes of Geffray Chaucer* was given was that edited by William Thynne in 1532 for Thomas Godfray. Of this there was a new edition in 1542 for John Reynes and William Bonham, and an undated reprint a few years later for Bonham, Kele, Petit and Toye, each of whom put his name on part of the edition. In 1561 a reprint, with numerous additions, edited by John Stowe, was printed by J. Kyngston for J. Wight and this was re-edited, with fresh additions by Thomas Speght, in 1598 for G. Bishop and again in 1602 for Adam Islip. In 1687 there was an anonymous reprint, and in 1721 John Urry produced the last and worst of the folios. By this time the paraphrasers were already at work, Dryden rewriting the tales of the Knight, the Nun's Priest and the Wife of Bath, and Pope the Merchant's. In 1737 (reprinted in 1740) the Prologue and Knight's Tale were edited (anonymously) by Thomas Morell "from the most authentic manuscripts," and here, though by dint of much violence and with many mistakes, Chaucer's lines were for the first time in print given in a form in which they could be scanned. This promise of better things was fulfilled by a fine edition of the *Canterbury Tales* (1775–78), in which Thomas Tyrwhitt's scholarly instincts produced a comparatively good text from second-rate manuscripts and accompanied it with valuable illustrative notes. The next edition of any importance was that edited by Thomas Wright for the Percy Society in 1848–51, based on the erratic but valuable British Museum manuscript Harley 7334. In 1866 Richard Morris re-edited this text in a more scholarly manner for the Aldine edition of the British Poets.

In 1868 the foundation of the Chaucer Society, with Dr. Furnivall as its director and chief worker, and Henry Bradshaw as a leading spirit, led to the publication of a six-text edition of the *Canterbury Tales*, and the consequent discovery that a manuscript belonging to the earl of Ellesmere, though undoubtedly "edited" contained the best available text. The Chaucer Society also printed the best manuscripts of *Troilus and Criseyde* and of all the minor poems, and thus cleared the way for the "Oxford" Chaucer, edited by Prof. Skeat, with a wealth of annotation, for the Clarendon Press in 1894, the text of which was used for the splendid folio printed two years later by William Morris at the Kelmscott Press, with illustrations by Sir Edward Burne-Jones. A supplementary volume of the Oxford edition, entitled *Chaucerian and other Pieces*, issued by Prof. Skeat in 1897, contains the prose and verse which his early publishers and editors, from Pynson and Thynne onwards, included among his Works by way of illustration, but which had gradually come to be regarded as forming part of his text. Many of these pieces have now been traced to other authors, and their exclusion has helped to clear not only Chaucer's text but also his biography, which used (as in the "Life" published by William Godwin in two

quarto volumes in 1803) to be encumbered with inferences from works now known not to be Chaucer's, notably the *Testament of Love* written by Thomas Usk. *See* Eleanor P. Hammond, *Chaucer; a Bibliographical Manual* (1909); J. S. P. Tatlock and A. G. Kennedy, *A Concordance to the Complete Works of Geoffrey Chaucer and to the Romaunt of the Rose* (Carnegie Institute, 1927). (A. W. P.)

CHAUDESAIGUES, a village of central France, in the department of Cantal, at the foot of the mountains of Aubrac, 19 mi. S.S.W. of St. Flour. Pop. (1936) 953. It has hot mineral springs, which at their maximum rank as the hottest in France. The water, which contains bicarbonate of soda, is employed medicinally, and also for washing fleeces, incubating eggs and various other economic purposes; and it furnishes a ready means of heating the houses of the town during winter. In the immediate neighbourhood is the cold chalybeate spring of Condamine. The warm springs were known to the Romans, and are mentioned by Sidonius Apollinaris.

CHAUFFEUR. In its anglicized sense, the common name for a professional driver of a motor vehicle. The word is French (from *chauffer*, to heat) and, primarily used for a man in charge of a forge or furnace, came to describe a stoker on a locomotive or steamship.

CHAULIAC, GUY DE (Guido de Cauliaco) (*c.* 1300–1368), French surgeon, was born at Chauliac (Auvergne). He took holy orders and studied at Toulouse, Montpellier and Paris, and then went to Bologna to study anatomy under Nicolo Bertuccio. Chauliac was one of the most learned men of his time, and his book, *Chirurgia magna* (1363), passed through many translations and was for a long time the standard work on the subject, though it tended to retard progress in surgery by advocating meddlesome treatment of wounds. It was first printed in French at Lyons in 1478. In his *Capitulum singulare* he qualifies as an important medical historian. Guy died on July 25, 1368, at Avignon, where he was physician to the pope. He operated for hernia and cataract, which had hitherto been treated mainly by charlatans, and has left a description of the narcotic inhalation given to patients.

See Fielding H. Garrison, *History of Medicine*, p. 156-158 (1929); Arturo Castiglioni, ed. by E. B. Krumbhaar, *History of Medicine*, p. 345-347 (1941).

CHAULIEU, GUILLAUME AMFRYE DE (1639–1720), French poet and wit, was born at Fontenay, Normandy. His father, *maître des comptes* of Rouen, sent him to study at the Collège de Navarre. Louis Joseph, duke of Vendôme, and his brother Philippe, grand prior of the Knights of Malta in France, at that time had a joint establishment at the temple, where they gathered round them a very gay and reckless circle. Chaulieu received the abbey of Aumate and other benefices from the duke; and became the constant companion and adviser of the two princes. He made an expedition to Poland in the suite of the marquis de Béthune, but returned to Paris without securing any advancement. In his later years Chaulieu spent much time at the little court of the duchesse du Maine at Sceaux. There he became the trusted and devoted friend of Mdlle. Delaunay. Among his poems the best known are "Fontenay" and "La Retraite."

Chaulieu's works were edited, with those of his friend the marquis de la Fare, in 1714, 1750 and 1774. *See* also C. A. Sainte-Beuve, *Causeries du lundi*, vol. i; and *Lettres inédites* (1850), with a notice by Raymond, marquis de Berenger.

CHAUMETTE, PIERRE GASPARD (1763–1794), French revolutionary, was born at Nevers on May 24, 1763. Until the revolution he lived a somewhat wandering life, interesting himself particularly in botany. He was a student of medicine at Paris in 1790, became one of the orators of the club of the Cordeliers, and contributed anonymously to the *Révolutions de Paris*. As member of the insurrectionary Commune of Aug. 10, 1792, he was delegated to visit the prisons, with full power to arrest suspects. He was elected president of the Commune, defending the municipality in that capacity at the bar of the convention on Oct. 31, 1792. Chaumette was one of the ringleaders in the attacks of May 31 and of June 2, 1793, on the Girondists, towards whom he showed himself relentless. He was one of the promoters of the worship of reason, and on Nov. 10, 1793, he presented the goddess to the convention in the guise of an actress. On the 23rd he obtained a decree closing all the churches of Paris, and placing the priests under strict surveillance; but on the 25th he retraced his steps and obtained from the commune the free exercise of worship. Robespierre had him accused with the Hébertists; he was arrested, imprisoned in the Luxembourg, condemned by the revolutionary tribunal and executed on April 13, 1794. Chaumette was an ardent social reformer; he secured the abolition of corporal punishment in the schools, the suppression of lotteries, of houses of ill-fame and of obscene literature; he instituted reforms in the hospitals, and insisted on the honours of public burial for the poor.

CHAUMONT, a town of eastern France, capital of the department of Haute-Marne, a railway junction 163 mi. E.S.E. of Paris on the main line of the Eastern railway to Belfort. Pop. (1936) 17,389. Chaumont is situated on high ground at the confluence of the Marne and Suize. It received a charter from the counts of Champagne in 1190. The church of St. Jean-Baptiste dates from the 13th century, the choir and lateral chapels belonging to the 15th and 16th. The sculptured triforium (15th century), the spiral staircase in the transept and a Holy Sepulchre are of interest. The Tour Hautefeuille (a keep of the 11th century) is the principal relic of a château of the counts of Champagne; the rest of the site is occupied by the law courts. In 1814 Great Britain, Austria, Russia and Prussia concluded at Chaumont the treaty by which they bound themselves not to conclude a separate peace and to prosecute the Napoleonic war to a successful issue. Chaumont is the seat of a prefect and of a court of assizes, and has tribunals of first instance and of commerce. The main industries are glovemaking and leather dressing. The town has trade in grain, iron (mined in the vicinity) and leather.

CHAUNCEY, ISAAC (1772–1840), U.S. naval commander was born at Black Rock, Conn., Feb. 20, 1772. He was brought up in the merchant service, and entered the U.S. navy as a lieutenant in 1798. The most active period of his life was that of his command on the Great Lakes during the War of 1812. He took the command at Sackett's harbour on Lake Ontario in Oct. 1812. Commodore Chauncey brought from 400 to 500 officers and men with him, and local resources for building being abundant, he had by November formed a squadron of ten vessels, with which he attacked the Canadian port, York, taking it in April 1813. The Americans had the advantage of commanding greater resources for shipbuilding. Sir James Yeo began by blockading Sackett's harbour early in 1814, but when the U.S. squadron was ready he was compelled to retire by the disparity of the forces. Commodore Chauncey was now able to blockade the British flotilla at Kingston. During his later years he served as commissioner of the navy, and was president of the board of naval commissioners from 1833 till his death at Washington, Feb. 27, 1840.

See Roosevelt's *War of 1812* (1882); and A. T. Mahan, *Sea Power in its Relations to the War of 1812* (1905); also *see* E. Channing, *History of the United States*, vol. iv (1926).

CHAUNCY, CHARLES (1592–1672), president of Harvard college, was born at Yardley-Bury, England, in Nov. 1592, and attended Trinity college, Cambridge. He was in turn vicar at Ware and at Marston St. Lawrence, but twice incurred censure from the authorities for nonconformity. His formal recantation in Feb. 1637 caused him lasting self-reproach. In this same year he emigrated to America, where he was an associate pastor at Plymouth, then pastor at Scituate (Mass.), and, from 1654 until his death, president of Harvard college. He died on Feb. 19, 1672. According to Mather, he was "a most incomparable scholar." His writings include: *The Plain Doctrine of the Justification of a Sinner in the Sight of God* (1659) and *Antisynodalia Scripta Americana* (1662).

His great-grandson, Charles Chauncy (1705–1787), a prominent U.S. theologian, was born in Boston (Mass.), on Jan. 1, 1705, and graduated at Harvard in 1721. In 1727 he was chosen as the colleague of Thomas Foxcroft in the First Church of Boston, continuing as pastor until his death. He condemned

the "Great Awakening" as an outbreak of emotional extravagance in his sermon *Enthusiasm,* and in his *Seasonable Thoughts on the State of Religion in New England* (1743), written in answer to Jonathan Edwards' *Some Thoughts Concerning the Present Revival of Religion in New England* (1742). Before and during the War of Independence he ardently supported the patriot party. He died in Boston on Feb. 10, 1787. His publications include: *Salvation of All Men, Illustrated and Vindicated as a Scripture Doctrine* (1782) and *Five Dissertations on the Fall and its Consequences* (1785).

For Charles Chauncy *see* Cotton Mather's *Magnalia Christi Americana* (1702) and W. C. Fowler's *Memorials of the Chauncys* (1858). For the younger Chauncy *see* P. L. Ford's privately printed *Bibliotheca Chaunciana* (1884), and Williston Walker's *Ten New England Leaders* (1901).

CHAUNY, a town of northern France in the department of Aisne, 19 mi. S. by W. of St. Quentin by rail. Pop. (1946) 9,330. The town is situated on the Oise (which here becomes navigable) and at the junction of the canal of St. Quentin with the lateral canal of the Oise. It contains mirror-polishing works, chemical works and metal foundries. It was the scene of much fighting in the Hundred Years' War.

CHAUTAUQUA, Chautauqua county, N.Y., U.S., a summer centre of music, popular education and recreation, is located on the beautifully wooded west shore of Chautauqua lake. The resident population in 1950 was 4,082, but the summer program of symphony concerts, lectures, plays, operas, summer-school courses, religious works activities and recreation attracts an average of 50,000 summer visitors.

Originally established as a Sunday school assembly in 1874 by John Heyl Vincent and Lewis Miller, it operates about 30 public buildings and an outdoor amphitheatre seating 7,000 persons. Chautauqua maintains the Chautauqua Literary and Scientific circle founded in 1878.

CHAUVIGNY, a town of western France in the department of Vienne, 20 mi. E. of Poitiers by rail. Pop. (1946) 3,914. The town is finely situated overlooking the Vienne, and has two interesting Romanesque churches, both restored in modern times. It was a strong fortress in the middle ages, and still possesses the ruins of no less than five castles, the chief of which is the Château Baronnial (11th and 15th centuries) the old seat of the bishops of Poitiers, who were lords of Chauvigny.

CHAUVINISM, a term for unreasonable and exaggerated patriotism, the French equivalent of "Jingoism." The word originally signified idolatry of Napoleon, being taken from a much-wounded veteran, Nicholas Chauvin, who, by his adoration of the emperor, became the type of blind enthusiasm for military glory.

CHAUX DE FONDS, LA, an industrial town in the Swiss canton of Neuchâtel, about 19m. by rail N.W. of Neuchâtel, at a height of about 3,250ft. in a valley of the same name in the Jura. Pop. (1930) 35,252; mainly Protestant (27,306) and French-speaking; of the Catholic faith, the majority are "Old Catholics." It is a centre of the watch-making industry. There are schools of watch-making and of industrial art.

See *Dict. hist. et biogr. de la Suisse,* ii.

CHAVANTEAN, a small independent linguistic stock of South American Indians, so called from the Chavantes or Cainangs, its most important tribe. The Chavantean tribes are found today on the upper Parana and Lower Paranapanema rivers, in the state of São Paulo, Brazil. They formerly occupied a somewhat larger territory. These Chavantes are to be carefully distinguished from the tribe of the same name in the States of Goyaz and Matto Grosso, who belong to the Ges stock. The Chavantes are quite dark-skinned, rather timid hunting folk, of very primitive culture. They are very little known. Both sexes wear small bast breech-clouts, but no other clothing. Their dwellings are tiny thatched huts, and their weapons the bow and spear. They have no pottery or textiles.

See H. von Ihering, *The Anthropology of the State of S. Paulo, Brazil* (2nd ed. S. Paulo, 1906).

CHAVASSE, FRANCIS JAMES (1846–1928), the son of Thomas Chavasse, of Sutton Coldfield, and brother of Sir Thomas Chavasse, the Birmingham surgeon, was born on Sept. 27, 1846. He was educated privately, and later at Corpus Christi college, Oxford. He was ordained in 1870, and in 1878 became vicar of St. Peter-le-Bailey, Oxford, and a year later principal of Wycliffe hall. In 1900, on the resignation of Dr. J. C. Ryle, the first bishop of Liverpool, Chavasse was appointed to the vacant see. He was remarkable for his ability in finding common interests for people of very different types and holding very different views, and in bringing them together to work for a common purpose. This gift proved invaluable in the execution of the great scheme for the building of Liverpool cathedral (on the plans designed by Sir Giles Gilbert Scott, R.A.) with which his name will always be associated. He resigned his bishopric in 1923, owing to his advanced years, and died on March 11, 1928.

CHAVES, a town of northern Portugal, in the district of Vila Real, 8 mi. S. of the Spanish frontier. Pop. (1940), 8,822. Chaves is the ancient *Aquae Flaviae,* famous for its hot saline springs, which are still in use. A fine Roman bridge of 18 arches spans the Tamega. Chaves was long one of the principal frontier fortresses, and may derive its present name from the position which makes it the "keys" (*chaves*) of the north. One of its churches contains the tomb of Alphonso I. of Portugal (1139–85).

CHEADLE, a small town in the urban district of Cheadle and Gatley (pop. 1938, 26,220), in Cheshire, England, 6m. S. of Manchester. The name occurs in the formerly separate villages of Cheadle Hulme, Cheadle Bulkeley and Cheadle Moseley. Cheadle is one of the numerous townships of modern growth which fringe the southern boundaries of Manchester, and practically form suburbs of that city. Stockport lies immediately to the east. There are cotton printing and bleaching works in the locality.

CHEADLE, market town of north Staffordshire, England, 10 mi. E. of Stoke, on the L.M.S.R. Pop. civil parish (1931) 6,754. The Roman Catholic church of St. Giles, with a lofty spire, was designed by Pugin and erected in 1846. There are three collieries in the neighbourhood, and a large textile manufactory in the town. Metal-working is also carried on.

CHEATING, "the fraudulently obtaining the property of another by any deceitful practice not amounting to felony, which practice is of such a nature that it directly affects, or may directly affect, the public at large" (Stephen, *Digest of Criminal Law*). Cheating is either a common law or statutory offence, and is punishable as a misdemeanour. An indictment for cheating at common law is of comparatively rare occurrence, and the statutory crime usually presents itself in the form of obtaining money by false pretences (*q.v.*).

CHEBICHEV, PAFNUTIY LVOVICH (1821–1894), after N. I. Lobachevskiy, the most distinguished of Russian mathematicians, was born at Borovsk on May 26, 1821. Educated at the University of Moscow in 1859, he became professor of mathematics in the University of St. Petersburg, a position from which he retired in 1880. He became a correspondent in 1860, and in 1874 *associé étranger* of the Institute of France. He was also a foreign member of the Royal Society of London. In 1841 he published a valuable paper, "Sur la convergence de la série de Taylor," in *Crelle's Journal.* He wrote much on prime numbers; in one paper ("Sur les nombres premiers," 1850) he established the existence of limits within which must be comprised the sum of the logarithms of the primes inferior to a given number. He devoted much attention to the problem of obtaining rectilinear motion by linkage. The "Chebichev's parallel motion" is a three-bar linkage, which gives a very close approximation to exact rectilinear motion, but he failed to devise one producing true rectilinear motion. Such a linkage was discovered by one of his pupils, Lipkin, who, however, had been anticipated by A. Peaucellier. His mathematical writings cover a wide range of subjects, such as the theory of probabilities, quadratic forms, theory of integrals, gearings, the construction of geographical maps, etc. He also published a *Traité de la théorie des nombres.* He died at St. Petersburg on Dec. 8, 1894.

CHEBOYGAN, a city of Michigan, U.S.A., on south channel of the Strait of Mackinac, at the mouth of the Cheboygan river; a port of entry and the county seat of Cheboygan county. It is on

federal highways 23 and 27, and is served by the New York Central and the Detroit and Mackinac railways, by air and bus lines, and by lake steamers during the navigation season. The population in 1950 was 5,507. Cheboygan is in the heart of the summer resort region of northern Michigan, and is surrounded by a farming, stock-raising and fruitgrowing country. The city has sundry manufacturing industries, and is an important fishing port. There are large apple orchards and an apple juice factory. Cheboygan (at first called Duncan and later Inverness) was settled in 1846 and chartered as a city in 1889. Cheboygan is the home port of the United States coast guard icebreaker "Mackinaw."

CHECHENO-INGUSHETIA. This autonomous republic in the North Caucasian area of the Russian Soviet Federated Socialist Republic was created an autonomous republic in 1936. Area 6,062 sq.mi. Pop. (1939) 697,408; 498,759 rural, 198,649 urban. It consists mainly of the densely wooded slopes of the Northern Caucasus and extends from the Caucasus to the Terek river, and from North Ossetian A.S.S.R. and Kabardino-Balkaria to Daghestan. In the north the forest thins out and its place is taken by steppe with chestnut brown soil less fertile than the black earth, but suitable for agriculture in years of good rainfall. The latter varies in quantity in the north but is more abundant on the southern hill slopes. The density of population is about 71 per sq.mi., the Chechens are the most numerous of the native hill tribes in the North Caucasian area, forming 68.4% of the total population. The Ingush represent only about 12.7% of the total population. The Chechen, Tchetchen (or Khists [Kisti], as they are called by the Georgians) call themselves "Nakhtche" (people). They fought fiercely against Russian aggression under Daûd Beg, Oman Khan and Shamyl, in the 18th century and under Khazi-Mollah in the 19th century. Many of them migrated to Armenia in 1859, after the surrender of their chieftain Shamyl. They are Mohammedans, and they are governed by popular assembly in each commune, every man considering himself free and equal to his neighbour. Towards the north settled agriculture has been introduced by Russian immigrants and winter wheat, millet, oats and barley are grown. Working cattle are used in preference to horses. But, in the southern hill oak, beech, birch and pine forest and alpine pasture area, the Chechens are hunters or nomad herdsmen, taking their goats and sheep to the high meadows in the spring, and descending in autumn to the lower more sheltered areas. They sow oats and barley under great difficulties, often having to remove the stones brought down by the spring floods from their tiny cultivated patches and even in summer snow may fall.

Their goats supply them with milk, and their sheep with meat, leather and wool. Koustar (peasant) industries include spinning, weaving, preparing leather and the making of knives and daggers. Bees are kept and a sawmilling industry is being developed.

Cultural life is at a low level, there is a high percentage of illiteracy, and this combined with the absence of roads and the impossibility of using the mountain streams, the Sunzha and Argun and their tributaries for passenger navigation, makes cultural and economic progress difficult. Many mountain Chechens and Ingush alike live in windowless hovels of mud and stone in the winter and, in the summer, on the Alpine pastures, improvise shelters from boughs.

The two main roads are from Grozny to Shatoi on the Argun river, and a road farther east almost parallel to it passing south into Daghestan. There is telegraphic communication along these roads.

From Gydermes junction a loop of the Caspian-Black sea railway passes through Grozny to Beslan, from which a branch goes to Orjonikidze (Vladikavkaz).

CHECKERS, the name by which the British game of draughts is known in the United States.

See DRAUGHTS OR CHECKERS.

CHEDDAR, town, Somerset shire, England, 18 W. of Bristol by G.W.R. Pop. (1951) 1,154. To the west lies the low Axe valley, to the east rise immediately southwest the Mendip cliffs (600–800 ft.) of Cheddar gorge, with beautiful stalactitic caverns, of which Cox's and Gough's are best known. The remains discovered in the caves (particularly Gough's after 1928) and elsewhere in the neighbourhood give evidence of prehistoric and Roman settlements at Cheddar (*Cedre, Chedare*), which was a convenient trade centre. The manor of Cheddar was a royal demesne in Saxon times, and the witenagemot was held there in 966 and 968. It was granted by John in 1204 to Hugh, archdeacon of Wells. The bishop of Bath and Wells granted it to the king in 1553. It is now owned by the marquess of Bath. By charter of 1231 extensive liberties in the manor of Cheddar were granted to Bishop Joceline, who in 1235 obtained the right to hold a weekly market and fair. By a charter of Edward III (1337) Cheddar was removed from the king's forest of Mendip. The market and stock fairs have long been discontinued, the former in about 1690. The name of Cheddar is given to a well-known species of cheese, the manufacture of which began in the 17th century in the town and neighbourhood.

CHEDUBA or MAN-AUNG, an island in the Bay of Bengal, situated 10 mi. from the coast of Arakan, between 18° 10′ and 18° 36′ N., and between 93° 31′ and 93° 50′ E. It forms part of the Kyaukpyu district of Arakan. It extends about 20 mi. in length from north to south, and 17 mi. from east to west, and its area of 220 sq.mi. supports a population of nearly 30,000. The channel between the island and the mainland is navigable for boats, but not for large vessels. The surface of is richly diversified by hill and dale and in the southern portion some of the heights exceed 1,000 ft. in elevation. There are various indications of former volcanic activity, and along the coast are earthy cones covered with green-sward, from which issue springs of muddy water emitting bubbles of gas. Copper, iron and silver ore have been discovered; but the island is chiefly noted for its petroleum wells. The inhabitants of the island are mainly Maghs. Cheduba fell to the Burmese in the latter part of the 18th century, and was taken by the British in 1824.

CHEERING, the uttering or making of sounds encouraging, stimulating or exciting to action, indicating approval or acclaiming or welcoming persons, announcements of events and the like. The word "cheer" meant originally face, countenance, expression (Low Lat. *cara*), and was at first qualified with epithets, both of joy and sorrow; compare "She thanked Dyomede for alle his gode chere" (Chaucer, *Troylus*) with "If they sing . . . to with so dull a cheere" (Shakespeare, *Sonnets*, xcvii.). An early transference in meaning was to hospitality or entertainment and hence to food and drink "good cheer." The sense of a shout of encouragement or applause is a late use.

Of the different words or sounds that are used in cheering "hurrah," though now generally looked on as the typical British form of cheer, is found in various forms in German, Scandinavian, Russian (*ura*), French (*hourra*); it is probably onomatopoeic in origin. The German *hoch*, the French *vive*, Italian and Spanish *viva, evviva*, are cries rather of acclamation than encouragement. The Japanese shout, *banzai*, became familiar during the Russo-Japanese War. In reports of parliamentary debates "cheers" indicates that approval was shown by emphatic utterances of "hear hear." Cheering may be tumultuous or it may be concerted rhythmically by prearrangement, as in the case of the "Hip-hip-hip" by way of introduction to a simultaneous "hurrah."

Rhythmical cheering has been developed to its greatest extent in America in the college yells, which may be regarded as a development of the primitive war cry. The original yells of Harvard and Yale are identical in form, being composed of *rah* (abbreviation of *hurrah*) nine times repeated, shouted in unison with the name of the university at the end. The Yale cheer is given faster than that of Harvard. Many institutions have several different yells; the best known of these variants is the Yale cheer, partly taken from the *Frogs* of Aristophanes:

Brekekekéx, ko-áx, ko-áx,
Brekekekéx, ko-áx, ko-áx,
O-óp, O-óp, parabaloú,
Yale, Yale, Yale,
Rah, rah, rah, rah, rah, rah,
rah, rah, rah,
Yale! Yale! Yale!

The "triple cheer" of Princeton is:

H'ray, h'ray, h'ray,
Tiger, tiger, tiger,
Siss, siss, siss,
Boom, boom, boom,
Ah, ah, ah,
Princetón, Princetón, Princetón!

The "railroad cheer" is like the foregoing, but begun very slowly and broadly, and gradually accelerated to the end, which is enunciated as fast as possible. Many cheers are formed like that of Toronto university

Varsitý, varsitý,
V-a-r-s-i-t-y (spelled)
VARSIT Y (spelled *staccato*)
Vár-si-tý,
Rah, rah, rah!

The cheer of the United States Naval academy is an imitation of a nautical siren. The Amherst cheer is

Amherst! Amherst! Amherst! Rah! Rah!
Amherst! Rah! Rah!
Rah! Rah! Rah! Rah! Rah! Rah! Amherst!

Besides the cheers of individual institutions there are some common to all, generally used to compliment some successful athlete or popular professor. One of the oldest examples of these personal cheers is:

Who was George Washington?
First in war,
First in peace,
First in the heárts of his countrymén.

followed by a stamping on the floor in the same rhythm.

College yells are used particularly at athletic contests. In a large college there are several leaders, chosen by the students, who stand in front and call for the different songs and cheers, meeting with their arms in the fashion of an orchestral conductor. Cheering and singing form one of the distinctive features of intercollegiate and scholastic athletic contests in America.

CHEESE. The consolidated curd of milk is used as food in most parts of the world. The product is of many varieties, textures and flavours depending on the animal source (mainly the cow, less frequently the sheep or goat and rarely the mare, llama, reindeer, buffalo, zebra or yak), acidity, fat and other characteristics of the milk and the nature of the processing and curing which it undergoes. The result is that 100 lb. of milk is reduced to 8–12 lb. of a highly nutritious, semistorable food. Cheese contains nearly all the fat, casein, calcium and vitamin A and part of the milk sugar and salts of the milk from which it was made. It is difficult to present comprehensive food value figure for such a variable food but Cheddar and some other hard whole-milk cheeses are about 25% protein and 33% fat and give approximately 385 cal. per 100 g. retail weight.

The beginning of cheese making and its use by early herdsmen thousands of years ago is unrecorded. History does record the use of cheese by many early peoples, and the Old Testament contains a number of references to it. The Greeks and Romans are supposed to have had cheese as a staple food at least a thousand years before the beginning of the Christian era. The Jews and the Romans are said to have recognized the strength-giving properties of cheese and to have fed it to their armies because of its convenient concentrated form, and the Greeks gave it to their wrestlers to increase their endurance.

Production and Processing.—Cheese making has largely moved from the individual art stage to one of scientific technology. High-quality, clean milk from healthy animals, without undesirable odours and not overripe, is preferable and even necessary. Pasteurization of milk for cheese making has come into general use in some areas for some types, permitting better control of quality, a more uniform product and better keeping characteristics. The first successful applications were to soft, unripened types, but later the process was adapted to the ripened cheese types such as Cheddar. Treatment of milk to get cheese and the processing of the green cheese, depending partly upon cheese type desired but also upon equipment and technology available, have many variations.

Among the simpler steps involved with the American type are the following: A lactic acid starter may be introduced to attain the degree of acidity desired, after which the temperature of the milk is raised to about 86° F. colour added and enough rennet or pepsin added to coagulate the milk into a firm, jellylike curd in about 30 undisturbed minutes. The curd is then cut and stirred, the curd and whey heated slowly to 100–106° F. for one to two hours, at which time the curd reaches a desirable firmness, and the whey is removed. The curd is stirred, cooled to about 90° F. and salted, placed on a cap cloth, hooped and pressed under 40 to 60 lb. pressure for 30 to 60 minutes. Then the cap cloths are removed, surface fat is removed with warm water and the cheese is bandaged with light unbleached cotton cloth; the cap cloths are replaced and the cheese is rehooped and pressed for 6 to 24 hours under 100–200 lb. of pressure, at which time it should have developed a sound rind. It is then cured, preferably at 50–60° F. The bandage is removed if the humidity of the curing room is sufficiently high so that the rind does not become overdry and crack. In about six days the surface may be sufficiently dried to be paraffined, after which it is only necessary to turn the cheese periodically or otherwise care for it to keep it clean and free from mould. Depending partly on the temperature of the curing room it may reach a desirable body and flavour for consumption in about six weeks but it may be held five months or longer.

VARIETIES OF CHEESE

There are several possible ways of classifying cheeses, no one of which seems satisfactory for all purposes. For one purpose it may be more desirable to classify them according to methods of making; for another purpose the characteristics of the cheese may be more satisfactory. One common classification recognizes three groups—soft, semihard and hard. This grouping, however, is based almost entirely on the texture of the product when it is ready for consumption. In general the soft cheeses are those made by souring the milk with lactic acid, they are eaten within a few days after making. The hard cheeses are those made by coagulating the protein with rennet, cooking and pressing the curd and ripening with moulds or bacteria for several months or several years before they are ready to be eaten. Semihard cheeses fall between these two groups, and the process may have features in common with both.

All these types of cheese are known as the "natural" cheeses. Many of them are subjected to further treatment or processing, even smoking, which has the effect of producing an entirely new or different product known as "processed cheese." In making processed cheese, one or more lots of a natural cheese or of several kinds of natural cheese or of cheeses of different ripeness or inferior texture and flavour may be ground up, melted and blended with various seasoning materials. The liquid then forced into forms of the shape desired, cooled and packaged in containers for direct sale to consumers. The manufacture of processed cheese, though a comparatively modern phase of the cheese industry, developed rapidly.

Methods of making and handling cheese evolved more or less independently in widely separated regions. In many instances the practices were closely associated with local conditions of climate, agriculture and habits of the people, which not only resulted in characteristic differences in cheeses made in the different regions but also gave rise to a vast number of names. Apparently it was the custom of the earliest cheese-making peoples to name the product after the village or country in which it was made. In many instances local and regional names represent no real difference in type from that of cheese made under other names elsewhere, although the cheeses made in the various localities and countries may have certain distinguishing characteristics. Frequently these differences may be only in the shape or size of the cheese, or they may be in the flavour and texture resulting from different methods of cooking the curd or curing the cheese. Differences in ripening practices may give rise to considerable differences in quality even in cheese made from the same curd. Although cheese is marketed throughout the world under 400 to

500 different names, there are probably only about 18 distinct varieties.

Some of the distinctive differences in these varieties as briefed from K. J. Matheson (see *Bibliography*, below) are as follows:

Brick cheese is strictly an American product. Its name is supposed to have come from its shape or from the practice of using bricks to weight down the curd in the moulds. The curd is pressed in the small moulds—about 3 by 6 by 10 in.—for 24 hours, after which the prints are removed, salted and taken to the curing cellar where the cheese ripens in two or three months. Brick cheese has a strong, sweetish taste somewhat like Emmentaler or Swiss cheese and an aroma mildly resembling Limburger. The body of the cheese is rather elastic and contains numerous small, round holes or eyes.

Caciocavallo cheese is a peculiar kind of cheese made from either whole or partly skimmed milk of cows. It originated in Italy several centuries ago. One explanation of the name, which means literally "horse cheese," is that the cheese was first made in the region of Monte Cavallo; another is that the imprint of a horse's head appeared on each cheese as a trade mark of the original maker. The curd is moulded into any desired shape or size, usually about three pounds, and after the moulded shapes have been immersed in brine for several days they are suspended in pairs from the ceiling and smoked. The most common shape resembles a beet, the constriction at the top being caused by the string by which it hangs. This cheese is sometimes eaten while comparatively fresh, but is more frequently kept for months, then grated and used in soups or macaroni and similar foods. A small quantity is imported into the United States, and some is made in Wisconsin, Michigan and Pennsylvania.

Camembert cheese is a soft rennet cheese made from cows' milk. A typical cheese is about 4¼ in. in diameter and 1 in. thick, and as marketed in the United States is usually found wrapped in paper and enclosed in a wooden box of the same shape. The cheese usually has a rind about ⅛-in. thick, which is composed of moulds and dried cheese. The interior is yellowish in color and waxy, creamy or almost fluid in consistency, depending largely upon the degree of ripeness. The flavour is similar to Limburger but not so strong. Four to six weeks of ripening is required before this cheese is in condition for the market. Camembert cheese is said to have originated in 1791 in the locality from which it derives its name in the northwestern part of France. Cheese of the same type, however, is made in other parts of France and also in other countries, including New York and Wisconsin in the United States.

Similar types are known as Brie, Coulommiers, Robbiola and Ripened Neufchâtel.

Cheddar cheese gets its name from the village of Cheddar in Somersetshire, England, where it was first made many years ago. It is very popular as a food product both in England and in the United States. It was exported from the United States as early as 1790 and is today the most important variety made in that country, its manufacture accounting for about 90% of the total cheese production. The cheese is made from whole milk of cows or from skim milk or partly skimmed milk. The term "Cheddar" as known and used today refers principally to a phase of the making process. The finished cheese may be white or yellow, and it may be used after only three or four months of ripening, when it has a very mild flavour, or after one or two years of curing to develop a sharp or snappy flavour. American Cheddar cheese is frequently known and retailed merely as American or "store" cheese, "cream," "Yankee," "Wisconsin" or "New York" cheese. In California this cheese is known as Jack or Monterey cheese. It is made in several sizes and shapes with more or less distinguishing names such as Long Horns, Daisies, Twins, Flats and Cheddars or Exports. These sizes range from 5 to 16 in. in diameter, 4 to 16 in. in height and 10 to 100 lb. in weight. This variety has been packaged and cured in cans, to afford a convenient and attractive form in which to merchandise it. A one-way valve on the can permits ripening gases to escape and excludes air; thus curing in the can is possible.

Cottage cheese is an unripened, soft, sour-milk cheese made extensively in the United States, where it is often called Dutch cheese or smearcase. It is made both in the home and in the factory, from skim milk, with or without the addition of rennet. It is highly nutritious and palatable, contains all the food value of milk except the cream, and may be used as the main part of the meal or in salads, desserts or cooked dishes. Properly made, it has a clean, milk, acid flavour and smooth texture. Factory production increased markedly during and after World War I, as a result of educational campaigns directed toward the utilization of skim milk to conserve meats and other foods. The cheese is perishable and must be kept at low temperatures until consumed.

Cream cheese is a soft, mild, rich, uncured cheese made of cream or a mixture of cream and milk. In general, lactic acid culture, with or without rennet, is added to the pasteurized cream or cream mixture, which may be homogenized. It is held until it coagulates. The coagulated mass may be warmed and stirred; it is then drained. The curd may be pressed, chilled, worked, seasoned with salt; or it may be heated, with or without added cream or milk, until it becomes fluid and then homogenized or otherwise mixed. Flavouring materials, such as pimentos, pineapple or relish, may be added. It is packed usually in foil in glasses with sealed metal tops. The finished cheese should contain not less than 33% of fat and not more than 55% of moisture.

Edam cheese is a hard rennet cheese produced in the Netherlands; it is also known as Katzenkopf, Tête de Maure and Manbollen. Formerly Edam cheese was made from whole milk on the farms in North Holland, but today it is usually made of skimmed milk. The genuine Edam cheese contains at least 40% fat, although many creameries make a cheese of the same shape with only 20% to 30% fat. All Edam cheese for export bears the government guarantee of the fat content. The cheese is round but flattened at the top and bottom, and the outside is coloured red; or the cheese is packed in tin foil and, for export to hot countries, in bladders or tins. When the cheeses are a few weeks old they are marketed and the ripening process continues in the warehouses of the cheese merchants. Some is made in Wisconsin, and the imported product is well known in all large markets.

Emmentaler cheese is a hard rennet cheese made from cows' milk and is somewhat sweetish in flavour. It is characterized by holes or eyes, about the size of a cent, about one to three inches apart throughout the cheese. This cheese originated in the Emmental valley of Switzerland and is a very old variety, reported as early as the middle of the 15th century in the canton of Emmental. Its manufacture in France in 1722 under the name of Gruyère is recorded. It is now made in every civilized country. That made in the United States is known as Domestic Swiss, and that in the region of Lake Constance is called Algau Emmentaler. Other local names are Bellunese, Formaggio Dolce, Fontine d'Aosta and Thraanen. Only the best grades are imported into the United States. The cheeses are like massive solid wheels, six inches thick and sometimes four feet in diameter, and weigh from 60 to 220 lb. each. Ripening requires three to six months. Scientific studies by the bureau of dairy industry of the U.S. department of agriculture established a controlled procedure in many factories, which facilitates the manufacture of a uniformly good-quality cheese. Whereas the original makers depended on nature to introduce the necessary bacteria into the milk, modern makers now introduce "pure cultures" to bring about the desired action as follows: (1) the *Lactobacillus bulgaricus* to check undesirable fermentation and to aid in controlling ripening, and (2) the use of an eye and flavour culture to aid in the development of eyes and flavour.

Gorgonzola cheese, known also as Stracchino di Gorgonzola, is a rennet Italian cheese made from whole milk of cows. Its name comes from Gorgonzola, near Milan, but very little of the cheese is now made there. The interior of the cheese is mottled or veined with a penicillium much like Roquefort. As seen on the markets of the United States, the surface of the cheese is covered with a thin coat resembling clay, said to be prepared by mixing barite or gypsum, lard or tallow and colouring matter. These cheeses are cylindrical, being about 12 in. in diameter and 6

in. height. As marketed they are packed with straw in wicker baskets. Well-made cheeses may be kept a year or longer, but much is consumed fresh in the region where it is made. In England a similar type of cheese, known as Stilton, is made from cows' milk and is imported in quantities into the United States.

Gouda cheese is a sweet-curd Netherlands cheese made from cows' milk. The full-cream Gouda is mainly a farm product made chiefly in the provinces of South Holland and Utrecht, with an average fat content of 50%. Gouda made in creameries from partly skimmed milk has a fat content of 20% to 40%. The fat content is guaranteed by the government mark on the cheese. In shape Gouda cheese is cylindrical with the sharp edges rounded off. The cheeses weigh from 6½ to 44 lb. Ripening requires six to eight weeks. This cheese is commonly found on the larger markets in the United States.

Hand cheese is so named because originally it was moulded by hand into its final shape. It is a sour-milk cheese, very popular among German peoples, and is made in many countries. The process varies in different localities, but in general the curd is cooled in moulds, then ground fine in a curd mill (in some kinds caraway seed is added), then ripened on shelves in the curing room. The cheese has a sharp, pungent odour and taste, which is very disagreeable to most people unaccustomed to it. It is known by such local names as Thuringia Caraway cheese; Ihlefeld in Mecklenburg; and Livlander in the U.S.S.R.

Limburger cheese is a soft rennet cheese made from cows' milk which may contain all the butter fat or may be partly or entirely skimmed. The best Limburger is undoubtedly made from the whole milk. This cheese has a very strong and characteristic odour and taste, weighs about two pounds and is about 6 by 3 in. in size. It requires about two months to ripen. The most common synonyms of Limburger are Backstein and Hervé. It has, however, many local names, such as Algau, Lanark, Marianhof, Morin, Saint Michels, Schutzen, Tanzenberg, Carinthian, Grotenhof, Emmersdorf, Briol and Lindenhof. Limburger cheese originated in the province of Lüttich, Belgium, in the neighbourhood of Hervé. Its manufacture spread to Germany and Austria, where it is very popular, and to the United States, where large quantities are made, mostly in New York and Wisconsin. Contrary to popular belief, Limburger is no longer imported into the United States, since the domestic product is of good quality and is made cheaply.

Neufchâtel cheese is a soft rennet cheese made extensively in France, from either whole or skim milk of cows. Bondon, Malakoff, Petit Carre and Petit Suisse are essentially the same as Neufchâtel but have slightly different shapes. Neufchâtel cheese is made in the same manner as cream cheese, except that a little less rennet is used. The standard package, wrapped in tin foil, is round and weighs 2½ to 3 oz., its dimensions being 1½ by 2½ in. Factories in the United States make a variation of the Neufchâtel cheese which is probably as good as the French variety. American makers attempt to vary this cheese by the use of condiments. Pimiento, or Pepper Cream, is a Neufchâtel cheese in which one pound of red peppers is used for every ten pounds of cheese. The peppers are ground very fine and thoroughly mixed; the whole is then moulded and kept in a cold place.

Parmesan cheese is the name in common use outside Italy for the cheese made and known in that country for centuries as Grana, the term "grana" or "granona" referring to its granular appearance when broken, which is necessary because of the hardness of the cheese, cutting being practically impossible. There are two quite distinct kinds of cheese, one made in Lombardy and the other in Emilia. Parma, situated in Emilia, has long been an important commercial centre for both kinds, and from this fact the name of Parmesan results. The use of the term "Parmesan," however, is sometimes restricted to the cheese made in Lombardy, the term "Reggian" being used to designate that made in Emilia. The cheeses are ripened in a cool, well-ventilated room, where they may be stored for years, the surface being rubbed with oil from time to time. The exterior of the cheese is dark green or black, because of colouring matter rubbed on the surface. A greenish colour in the interior has been attributed to contamination with copper from the vessels in which the milk is allowed to stand before skimming. Parmesan cheese when well made may be broken and grated easily and may be kept for an indefinite number of years. It is grated and used largely for soups and with macaroni. A considerable quantity of this cheese is imported into the United States and sells for a very high price.

Pecorino cheese is a sheep's milk cheese made in Italy, and there are numerous more or less clearly defined kinds. The most common sort is the one designated Cacio Pecorino Romano, or merely Romano. This varies considerably in size and shape. A cheese of ordinary size is about 10 in. in diameter and 6 in. in thickness and weighs from 2 to 25 lb. The interior is slightly greenish in colour, somewhat granular and devoid of eyes or holes. Ripening requires eight months or longer. The Pecorino Dolce is artificially coloured with annatto and subjected to considerable pressure in the process of manufacture. Pecorino Tuscano is a smaller cheese than the Romano, measuring usually 6 in. in diameter and 2 or 4 in. in thickness and weighing from two to five pounds. Among the sheep's milk cheeses bearing local names are the following: Ancona, Cotrone, Iglesias, Leonessa, Puglia and Viterbo. In the manufacture of Viterbo cheese the milk is curdled by means of a wild artichoke, *Cynara scolymus*.

Roquefort cheese is a soft rennet cheese made principally from sheep's milk, although some cows' milk and goats' milk may be added. Numerous imitations, such as Gex and Septmoncel, are made from cows' milk. One of the most striking characteristics is the mottled or marbled appearance of the interior of the cheese, resulting from the development of a penicillium, which is the principal ripening agent. The manufacture of Roquefort has been carried on in the southeastern part of France at least since the beginning of the 18th century, and is particularly important in the village of Roquefort, from which the cheese derives its name. One interesting phase of the making process is the sifting of mouldy bread crumbs between layers of curd as it is placed in the forms or hoops, to bring about the desired ripening. Formerly the manufacture of the cheese up to curing time was carried on by the shepherds themselves, but today centralized factories collect the milk and make the cheese, which is still cured in the natural caves near Roquefort. The cheese may be sold after from 30 to 40 days or may remain in the caves as long as five months, depending on the degree of ripening desired. This type of cheese is made from cows' milk in Denmark. In the United States this type has been made since 1918, from cows' milk and with artificial curing conditions. Such American-made cheese has been ripened in natural caves along the Mississippi river in Minnesota and in an abandoned shaft of a coal mine in Pennsylvania.

Sapsago cheese is made principally in Glarus, Switz., from sour skim milk of cows. It is also known as Schabzieger, Glarnerkäse, Grünerkäse and Kräuterkäse. It is claimed that it was made in the 13th century; its authentic history at least dates back to the 15th century. Sapsago is a small, hard, green cheese flavoured with the leaves of an aromatic clover grown for the purpose. It is shaped like a truncated cone, 4 in. high, 3 in. in diameter at the base and 2 in. at the top. A comparatively small quantity is shipped into the United States under the name of Sap Sago, where it usually sells at a low price and is used as a grated cheese.

Trappist cheese originated with the Trappists in 1885 in the monastery of Mariastern, near Banjaluka, in Bosnia. Fresh milk is used and rennet is added. The ripening period of the smaller cheeses is from five to six weeks in summer, but the cheese is usually shipped at the end of four or five weeks. It is pale yellow in colour and has a remarkably mild taste. The smallest size of the cheese made in the monastery referred to has a diameter of 6 in. and a height of 2 in. and weighs two or three pounds. A larger size measures 9 in. in diameter and 2½ in. in height and weighs about ten pounds. There is also a still larger size. The cheese is exported to a large extent to Austria and Hungary, the most important centres of the trade in these regions being Gratz and Budapest. It is, however, found in all large cities of Austria, and the demand appears to be constantly increasing. This cheese

is very probably the same as Port du Salut. A cheese which is probably identical with the Trappist or Port du Salut is made in the Trappist monastery at Oka, Quebec, and is known as Oka cheese.

TRADE AND CONSUMPTION

Cheese making was well established in European countries when the new settlers went to America, and it is evident the practices and methods they established were those with which they were familiar in their native countries. Thus Cheddar cheese became by far the most important in New England where the English colonists settled, and Swiss cheese later became an important variety in Wisconsin where immigrants from Switzerland established a settlement.

Originally cheese was made only on the farm both in Europe and in America. The earliest records indicating the growth and importance of cheese making in America are the export statistics of 1790, in which year the New England states, New York and Pennsylvania exported 15,000,000 lb. of farm-made cheese. It is generally believed that Jesse Williams of Oneida county, New York, was the first to operate under a factory system in 1851. By 1870 the factory production of cheese made up more than half the total cheese made. Farm cheese production gradually declined and has almost completely disappeared.

Total cheese production in the U.S. in 1952 was 1,135,000,000 lb., representing utilization of 11,341,000,000 lb. or 10.3% of the total milk supply. Of the cheese total, more than 90% was the "American" (mostly Cheddar) type. Wisconsin was the leading state, with more than half the total production and a virtual monopoly of some types. Wholesale prices of Cheddar are based on the Plymouth Wisconsin Cheese exchange.

The average U.S. civilian in 1952 consumed 7.5 lb. of cheese, 36% more than before World War II but less than half as much as was used in some of the western European countries. Rationing of cheese was prevalent during the war and in the United Kingdom continued as late as 1954.

The world geography of cheese production depends not only upon the distribution of the dairy cow and milk production but also upon the comparative advantage of possible competitive uses of the milk. Use as fresh whole milk normally has highest priority. But in Europe, North America and Oceania (the main producing areas) about one-fifth of all whole milk used in manufacture in 1950 went into cheese making, as compared with about 16% before World War II, an increase made possible mainly by a decrease in the amount of milk used for butter. As compared with prewar output, the United States largest producing country, was exceeding prewar levels in 1951 by approximately four-fifths and on a per capita basis, by about 40%. Moreover, the U.S., which was a large net importer of cheese before the war, had become a major net exporter.

TABLE I.—*Estimated Cheese Output in Principal Producing Countries*

(In thousands of pounds)

Country	Average, 1935–39	1951*
United States	1,274,000	3,115,500
France	700,000	661,000
Italy	824,218	611,000
Netherlands	455,000	470,000
New Zealand†	210,000	220,000
Argentina	61,850	186,000
Denmark	161,500	165,100
Sweden	77,050	120,000
Switzerland	111,120	116,800
United Kingdom	100,000	98,500
Australia†	19,400	93,200
Canada	110,000	85,000
Norway	40,000	61,000
Union of South Africa	19,165	21,000

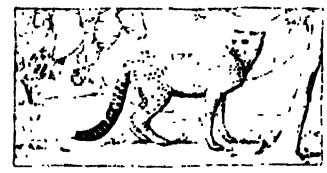
World trade in cheese in 1951 amounted to about 775,000,000 lb., nearly 30% more than before World War II. Some of the major exporting countries, particularly the United States, Italy, France and Canada, continued also to be large importers, emphasizing the fact that some of the numerous varieties serve special purposes. Bulk purchasing agreements, restrictive quotas and duties made the trade complex. At least 90% of New Zealand's exportable surplus was contracted to the United Kingdom at 176 shillings per hundredweight in 1952–53 for the first grade. In the United States several types of foreign cheese, amounting to about 25% of the imports, were freed from import controls in 1951 but quotas remained on several major types. The German Federal Republic substituted a 30% ad valorem duty for earlier weight duties.

TABLE II.—*International Trade in Cheese for the Major Trading Countries*



(In thousands of pounds)

Country	Average, 1934–38		1951*	
	Exports	Imports	Exports	Imports
Major exporting countries				
New Zealand	79,136,000	2	214,840	
Netherlands	120,000,000	244	156,100	781
Denmark	158,000	3	104,134	3

CHEETA, CHEETAH, CHITA or HUNTING LEOPARD (*Acinonyx jubatus*), a member of the family Felidae, distinguished by its claws being only partially retractile (see CARNIVORA). The cheeta attains a length of three to four feet; it is of a pale tawny colour, marked with numerous spots of black on the upper surface and sides and nearly white beneath. The fur is crisp, lacking the sleekness which characterizes the typical cats and the tail is long and bushy at the tip. The cheeta is found on the plains of Africa and southern Asia, and has been employed for centuries in Egypt and Persia in hunting antelopes and other game. It is taken to the field hooded and chained in a low car without sides. When the game is within about 200 yd. the cheeta is loosed. Over short distances, the cheeta can undoubtedly outrun any other animal. In India the name cheeta is applied also to the leopard.

THE CHEETA OR HUNTING LEOPARD

CHEF, in French a chief or head person; in English-speaking usage the head cook in a club or large private establishment or the head of the kitchen department in a large hotel or commercial catering organization. In general a chef is responsible for the conduct and operation of the food preparation in a large kitchen. He directs the staff of cooks, bakers and others required to prepare food for serving. He plans meals, prepares menus and sees that sanitary practices are observed. If a chef-steward he may be given complete control of kitchen, pantries and icehouses, including all purchasing and be expected to figure prices. If only a supervising chef, he is responsible only for the preparation of the food supplied to him from the stores department on requisition. He is usually expected to devise new recipes for preparing foods and more attractive ways for arranging them for service.

Every establishment preparing food on a large scale usually has a chef in charge of cooking operations. The constant growth of the hotel business and the commercial preparation of foods gives employment each year to a still larger number of chefs, though the requirements tend to become greater because of the demand for men having a more thorough knowledge of nutrition and food chemistry. For the most part, chefs are a product of an apprentice system. Young men start as assistant vegetable

man or even lower in the culinary scale, pass through a long line of specialized cooking positions such as vegetable cook, fry cook, roast cook (*rossetier*), roundsman, at times as baker or butcher, pastry man, cold meat chef (*garde manger*), until finally they become chefs, a process requiring from 4 to 8 years and frequent changes of employment. Schools for chefs and cooks are practically non existent in the U.S.A., though not unknown in Great Britain. The leading chefs in English-speaking countries have usually served an apprenticeship in central Europe or in France, whence they depart after completing their service. In some commercial establishments trained chemists and graduates from university schools of home economics often serve as chefs, though usually under a different title.

CHEFOO, former treaty port on the rocky north coast of the Shantung peninsula in northeast China (37° 33′ N., 121° 22′ E.). The port is naturally sheltered by outlying islands and in recent years these have been linked up by breakwaters to form a fully protected harbour. The port is more properly Yentai, Chefoo being a village across the harbour. Population (1931) 131,061. The tangled hill country of Shantung rises immediately behind Chefoo and its communications with the interior are only by pack-mule trails. A branch line of the Tsingtao-Tsinan railway was once projected. Chefoo was opened to foreign trade in 1863. It retained 10th place among Chinese ports until 1907, but decreased in importance after that year. It was the market for the tussore silk industry of the Shantung hills and raw silk constituted its staple export. A special trade had grown up between Chefoo in Shantung and the port of Antung across the Po Hai. After the Japanese occupation in 1938 the trade between Chefoo and Japan-controlled territory increased. The total value of import in 1940 was $10,948,565 (U.S.) and that of the exports was $3,203,744 (U.S.). Of this $2,819,055 (U.S.) entered Chefoo from Japan and $4,254,042 (U.S.) from Kwantung-leased territory, and the largest part of the export, $2,795,756 (U.S.), went to the U.S.A. The treaty port status of Chefoo was ended as a result of the English and U.S. treaties with China, Jan. 11, 1943, in which the foreign rights and privileges in China were given up.

CHEHALIS, a city of Washington U.S., 33 mi. S. by W. of Olympia, the county seat of Lewis county. It is on federal highway 99, and is served by four transcontinental railways and by the Cowlitz Chehalis and Cascade and the Chehalis and Western railways. Its manufacturing industries include lumber and shingle mills, brick and tile works, a cannery, drug manufacturing plant, fern packing and food-processing plants. The population in 1950 was 5,633.

CHEKE, SIR JOHN (1514–1557), English classical scholar, was one of the founders of Greek learning at Oxford. At St. John's college, Cambridge, where he became a fellow in 1529, he adopted the principles of the Reformation. In 1540, on Henry VIII.'s foundation of the regius professorships, he was elected to the chair of Greek. In a letter on the state of Greek learning at Cambridge to a fellow of St. John's college, Oxford, in 1542, his pupil, Roger Ascham, describes how Demosthenes had become as familiar as Cicero, and that Herodotus, Thucydides and Xenophon were more conned than Livy was in his student days. With Sir Thomas Smith, who shares with him the major part of the credit for the establishment of Greek studies at Cambridge, he introduced the "Erasmian" pronunciation of Greek in his lectures, rejecting the Italian and modern Greek method of giving various vowels and diphthongs the same sound, which the first western students had learned from Greek and Italian masters. It was strenuously opposed in the university, where the Reuchlinian" method favoured by Melanchthon prevailed, and Bishop Gardiner, as chancellor, issued a decree against it (June 4, 1542); but Cheke ultimately triumphed. On July 10, 1544, he was chosen tutor to Prince Edward who retained him in that capacity after his accession to the throne. Cheke sat as member for Bletchingly, for the parliaments in 1547 and 1553; in 1548 he was made provost of King's college, Cambridge (April 1548), was one of the commissioners for visiting that university as well as Oxford and Eton, and was appointed with seven divines to draw up a body of laws for the governance of the church. On Oct. 11, 1551 he was knighted; in 1553 he was made one of the secretaries of State, and sworn of the privy council. He filled the office of secretary of State for 11 days (July 6–17, 1553) and conducted his wealth. He was released on Sept. 13, 1553 and granted permission to travel abroad. He went first to Basle, then visited Italy giving lectures in Greek at Padua and finally settled at Strasbourg teaching Greek for his living. In the spring of 1556 he visited Brussels to see his wife; on his way back between Brussels and Antwerp, he and Sir Peter Carew were treacherously seized (May 1, 1556) by order of Philip of Spain, hurried over to England and imprisoned in the Tower. Cheke was terrified by a threat of the stake and giving way, was received into the Church of Rome by Cardinal Pole being cruelly forced to make two public recantations. He died in London on Sept. 13, 1557.

Thomas Wilson, in the epistle prefixed to his translation of the Olynthiacs of Demosthenes (1570), has a long and most interesting eulogy of Cheke, and Thomas Nash, in *To the Gentlemen Students*, prefixed to Robert Greene's *Menaphon* (1589), call him "the Exchequer of eloquence." Sir Thos. Chelk., a man of men, "supernaturally traded in all tongues." Many of Cheke's works are still in mss., some have been lost altogether. One of the most interesting from an historical point of view is the *Hurt of Sedition, how grievous it is to a Commonwealth* (1549), written on the occasion of Ket's rebellion, republished in 1569, 1576 and 1641, on the last occasion with a life of the author by Gerard Langbaine. Others are *D. Joannis Chrysostomi homiliae duae* (1543), *D. Ioannis Chrysostomi de providentia Dei* (1545), *The Gospel according to St. Matthew*, translated (c. 1550, ed. James Goodwin, 1843), *De obitu Martini Buceri* (1551) (Leo VI's) *de Apparatu bellico* (Basel 1554, but dedicated to Henry VIII. 1543), *Carmen Heroicum, ad epitaphium in Antonium Dencium* (1554), *De pronuntiatione Graecae linguae* (Basel, 1555). He also translated several Greek works and lectured admirably upon Demosthenes.

His life was written by John Strype (London 1705, Oxford 1821), additions by J. Gough Nichols in *Archaeologia* (1850) xxxviii. 38–127.

CHEKHOV, ANTON PAVLOVICH (1860–1904) Russian dramatist and story-writer born on Jan. 17, 1860, in Taganrog on the Sea of Azov. This name is also spelled Tchekhov, Tchehov and Chekhov. His father was a tradesman and the son of a serf. The writer was educated at the gymnasium of his native town, and in 1879 went to the University of Moscow where he studied medicine. He took his degree in 1884 but practised very little except during the cholera epidemic of 1892–93. He began his literary career while yet a student and soon became one of the most welcome contributors to the comic papers. His early stories appeared over the signature Antosha Chekhonte. In 1886 some of his stories were published in book form as *Particoloured Stories*. The book had a great success and attracted the attention of the publisher and editor Suvorin, who became his friend.

In 1887 he produced his first play *Ivanov*. In 1890 he travelled to the convict island of Sakhalin and the result of his journey was *Sakhalin Island* (1891–93), which had a considerable effect on the mitigation of the penal régime. From 1892 to 1897 he lived with his parents on a small estate he had acquired not far from Moscow. After 1897, as he was threatened with tuberculosis, he was forced to live the greater part of the year in the Crimea and abroad. In 1895 he produced his second play *The Seagull*, which was a complete failure in St. Petersburg (Leningrad). But in 1898 it was revived by the Moscow Art theatre of Stanislavsky and proved a great success. Henceforward Chekhov's connection with that theatre became very close. *Uncle Vanya* (1899), *The Three Sisters* (1901) and *The Cherry Orchard* (1904) were produced there. In 1901 he married the actress Olga Knipper. In 1900 he was elected an honorary fellow of the Academy of Science, but resigned his fellowship when the election of Maxim Gorky was cancelled by the Government. He died on July 2, 1904, at Badenweiler in the Black Forest.

Early Work.—The early stories of Chekhov, up to about 1886, are chiefly humorous. They are, in Russia, the most widely popular part of his work and more people know him by them than by *My Life* or *The Three Sisters*. Chekhov's humour is not strikingly above the level of the papers he wrote for. But very early he began to lay the foundations of that manner which is the essential Chekhov. Such a story as *The Chorus Girl* (1884) is almost

a mature masterpiece. It was, however, only after 1886 that he found the necessary leisure and independence to give definite expression to his imaginative experience. The years 1886–88 are a period of transition during which he experimented in various directions. To these years belong a series of stories of atmosphere against a background of nature (*The Steppe, Happiness, Easter Eve*) where the lyrical element of his genius received its fullest expression, and short stories of morbid experience in which the knowledge of the doctor is balanced by the sense of form of the artist. By 1889, however, he had attained perfection in his style. To this and the following years belong a succession of masterpieces, the principal of which are *A Dreary Story* (1889), *The Duel, Ward No. 6* (1892), *The Teacher of Literature* (1894), *Three Years: An Artist's Story,* in Russian *The House with the Maisonette* (1895), *Peasants* (1897), *The Darling, Ionitch, The Lady with the Dog* (1898), *The New Villa* (1899), *The Bishop* (1902).

Chekhov's art has been described as psychological, but his psychology ignores the individual. His characters are not persons but just men and women, the genus *homo*, an indifferentiated mass of humanity, divided into watertight compartments by the phenomenon of individuality, which does not make one being different from another but only inaccessible to him. A typical story by Chekhov is the life-story of a "mood," of a state of mind, usually of the relation of one person to another and the gradual transformation of that state of mind under the action of the incessant infinitesimal and unforeseen pinpricks of life. Sensitiveness to these pinpricks is the main feature of Chekhov's people, of those at least who are made to kindle the reader's sympathy, and the standard by which Chekhov gauges the worth of a human being. Those who suffer and succumb are the higher race, those who do not are unfeeling brutes. Hence a deep-rooted aversion (present in pre-Chekhov Russian literature, especially in Turgenev, but enormously magnified by Chekhov) for the strong and efficient man. None but "Hamlets" may receive sympathy.

The construction of Chekhov's stories may be described as musical or infinitesimal. It is at once fluid and precise. They are built along exactly calculated curves, of which only certain points are marked in the story, but each two points are sufficient to calculate the whole curve. The curve is the mood which begins as almost a straight line, then under the influence of "pinpricks" begins to deviate and at last shoots out in an entirely opposite direction. By far the greater number of Chekhov's stories end on a minor note, "not with a bang but a whimper." A story where the direction is in the opposite way, as in *The Lady with the Dog* (where the hero begins by regarding his love for the lady as a mere insignificant intrigue and ends in self-forgetful passion), is an exception. The "pessimistic," destructive, descendant tendency of the Russian novelists of the mid and later 19th century reaches its extreme expression in Chekhov, all the more extreme as it is so consistently muffled and "understated." To him, better than to anyone, the words of Albert Thibaudet apply, that a Russian story is always the story of the undoing of a life.

Somewhat apart from the other stories of Chekhov stand, what are perhaps his two masterpieces, *My Life* (1895) and *In the Ravine* (1900). They have a clearer and harder outline; they are free from the atmospheric, autumnal haze that pervades the others, and animated by a more active sense of moral and human values. *My Life*, especially, is a creation of vast and pregnant significance, with a symbolical grasp that gives it an almost religious character.

Chekhov's dramatic work consists of the same element as his narrative work. It includes numerous one-act plays which were extremely popular in Russia. Belonging to a later period than the comic stories, they are also on a higher artistic level. The serious plays are five in number—*Ivanov, The Seagull, Uncle Vanya, The Three Sisters, The Cherry Orchard.* They have many points in common with his stories; one main difference is that while the stories invariably centre round a single person from whose standpoint the situation is developed, the dramas have no such central figure, and all the characters have more or less equal rights on the stage. The plays are, as it were, symphonies for an orchestra of parts, and the resultant is arrived at by the complex interaction of the various voices. They are plays of "atmosphere," the English word that comes nearest to the Russian *nastroenie* (Stimmung). The principal thing in them is not the action but the emotional accompaniment of the action. In the "de-theatricalisation" of the theatre, in the complete avoidance of all traditional stage effects (though he introduced a new kind of "atmospheric" effect, as the famous string bursting at the end of *The Cherry Orchard*), Chekhov is the logical limit of the preceding development of the Russian drama. He did not go much further in this respect than Turgenev or Ostrovsky, but he built a more consistent dramatic system with a completely adequate technique.

The Novelist's Influence.—The influence of Chekhov on Russian literature has not been extensive. The last realists (Andreyev, Gorky, Bunin, etc.) learned little from him, and soon after his death the rise of an entirely new movement put an end to all possibility of continuing in his tradition. His plays were imitated by Gorky, Andreyev and others, but they invariably missed the constructive principle without which the whole system is stultified. To the Russia of to-day Chekhov is perhaps more alien than any other Russian writer of his rank.

On the other hand, his vogue and his influence outside Russia have of recent years grown immensely and were in 1927 probably near their zenith. England has proved particularly sensitive to his charm. He is almost universally regarded as the greatest Russian writer and as the greatest story-teller and dramatist of modern times. (D. S. M.)

CHEKIANG, the smallest but one of the most famous and densely peopled provinces of China. Area 40,169 sq.mi.; pop. 21,776,045 (1940). It is the most northerly of the coastal provinces of south China and is situated where the southwest to northeast ridges, so characteristic of southeast China, begin to sink beneath the alluvial plains of the delta of the Yangtze Kiang. The province falls naturally into two physiographic regions demarcated by the Tayu-ling, the northernmost ridge, which runs out to sea in the Chusan archipelago. The southern region consists of ridges and troughs parallel to the Tayu-ling and cut across by a number of transverse rivers. At the mouth of the largest of these, the Wu-kiang, lies Wenchow, the chief port of southern Chekiang. The northern region, drained for the most part by a single river, the Tsien-tang, with its outlet in Hangchow bay, consists essentially of the alluvial plains round the bay and of the foothills of the highlands. These northern plains are the most densely peopled part of the province participating in the life of the Yangtze delta and containing the well-known seaport of Ningpo and the beautiful capital city of Hangchow. This northern part of the province therefore resembles southern Kiangsu, while the rest is essentially similar to Fukien, which succeeds it on the south. Away from the plains around Hangchow bay flat land is rare and terraces stretch far up the mountain slopes.

The crops—wheat and beans, rice and cotton, tea and silk—are typical of mid-China, where the products characteristic of north and south overlap. On the slopes of the maritime ranges some of the best tea grown in the country is produced. The historical role of the province and many aspects of its culture reflect the pivotal position of Chekiang. Before the consolidation of China in the 3rd century B.C. north Chekiang was the core of the maritime state of Yüeh, which finally gained the mastery over the whole Yangtze delta. During the 12th and 13th centuries A.D. it had a larger significance, for Hangchow was then the capital of what remained of China to the Sung dynasty, retreating south-

wards before the Kin Tatars, and, after the Mongol conquest, it remained the acknowledged centre of Mangi. (*See* CATHAY.)

The province suffered severely through the Japanese invasion. After the fall of Hangchow, Christmas 1937, the Tsientang river temporarily formed the military line. Early in 1942 the Japanese attacked the airfields in western Chekiang and remained in possession of part of the territory. The occupation combined with deliberate destruction of Chinese sericulture brought great economic distress, little compensated by government sponsored development in the free part of the province.

Chekiang is linguistically divided. In the north, Wu dialects prevail, as in southern Kiang-su. The southwest speaks Mandarin as does neighbouring Kiangsi. In the south, Fukien dialects transgress the border.

CHELLEAN, the name given by the French anthropologist G de Mortillet to the first epoch of the Quaternary period when the earliest human remains are discoverable. The word is derived from the French town Chelles in the department of Seine-et-Marne. The Chellean epoch was interglacial, warm and humid as evidenced by the wild growth of fig-trees and laurels. The animals characteristic of the epoch are the *Elephas antiquus,* the rhinoceros, the cave-bear, the hippopotamus and the striped hyaena. Man existed and belonged to the Neanderthal type. The implements characteristic of the period are flints chipped into oval shaped forms and held in the hand when used. There is clear evidence of phases of Chellean industry—both in a simple and an advanced stage.

See Gabriel de Mortillet, *Le Préhistorique* (1900); M. C. Burkitt, *Prehistory* (1925); H. Peake and H. J. Fleure, *Apes and Men* (1927).

CHELM (Russian *Kholm*), a town of Poland, in the province of Lublin, 45 mi. by rail E.S.E. of Lublin. Pop. (1931) 29,224. It was founded in 1223 by Prince Daniel of Volhynia. Germany occupied Chelm during World War II.

CHELMNO (German *Kulm*), a small town of Poland, in the province of Pomorze (Pomerania), 1 mi. E. of the Vistula. Pop. (1931) 12,533. It is surrounded by 13th century walls, and contains two Roman Catholic and two Protestant churches and a mediaeval town-hall. There are large oil mills and an important trade in agricultural produce, including fruit and vegetables. Granted in 1226 by Conrad of Mazovia to the Teutonic Order, it became the base for their conquest of Prussia and the seat of the first Prussian bishopric. It always retained a large Polish population, which revolted against the Order and was re-annexed to Poland by the peace of Thorn in 1466. It was part of Prussia from 1773 to 1918, and Germany occupied it again during World War II. It was a prominent member of the Hanseatic League.

CHELMSFORD, FREDERICK JOHN NAPIER THESIGER, 1ST VISCOUNT (1868–1933), British administrator, born on Aug. 12, 1868, was the eldest son of Frederick Augustus, 2nd Baron Chelmsford. He was educated at Winchester and Magdalen college, Oxford, and held a fellowship at All Souls from 1892 to 1899. Having been called to the bar he was a member of the London school board for four years, and in 1904–5 served on the London county council. In the latter year, when he succeeded his father as Baron Chelmsford, he was appointed governor of Queensland and he held that office till 1909. These years saw the inauguration of the new policy of replacing the repatriated Kanakas by white labour. It was also a period of bitter political conflict. Chelmsford's action in granting the request of the premier, Philp, for a dissolution of parliament led to widespread agitation for the appointment of local governors in Australia. In Aug. 1909 Chelmsford left Queensland for New South Wales, of which State he was governor till 1913. It was a period of great development for the colony, and also of great labour unrest.

Chelmsford, who was created G.C.M.G. in 1912, served in India with the Dorset regiment in the early part of the World War. From April 1916 to the spring of 1921 he was viceroy of India. During this period the system of dyarchy, founded upon the joint report of the viceroy and the secretary of State, E. S. Montagu, was introduced. A considerable measure of autonomy was accorded to the provinces. The council of State and legislative assembly were to be elected, and the annual budget, with some reservations, submitted to the latter. Indians were given representation on the viceroy's council, and India was given the same power over tariffs as the Dominions.

But the new reforms were opposed by a combination of Hindus and Muslims under Gandhi, and a system of non-co-operation adopted, whilst the repressive legislation recommended by Mr. Justice Rowlatt's committee to deal with sedition provoked serious riots in Guzerat and the Punjab, culminating in the Amritsar disturbances (April 1919). However, an amnesty for political offences accompanied the promulgation of the reforms which were gradually accepted by moderate opinion. Meanwhile the viceroy had also to meet a Mohammedan agitation directed against British policy toward Turkey. This was actively supported by an Afghan army, after whose defeat the subsidy was withdrawn from the Amir, together with the privilege of importing arms from India. The new institutions were inaugurated by the duke of Connaught early in 1921. On his retirement Chelmsford was created a viscount and received Indian orders. He was first lord of the admiralty in Ramsay MacDonald's Labour Ministry of 1924. He died April 1, 1933. (G. LE G. N.)

CHELMSFORD, FREDERIC THESIGER, 1st BARON (1794–1878), lord chancellor of England, was the third son of Charles Thesiger, and was born in London on April 15, 1794. Young Frederic Thesiger was originally destined for a naval career, and he served as a midshipman on board the "Cambrian" frigate in 1807 at the second bombardment of Copenhagen. About this time he succeeded to a valuable estate in the West Indies, so he left the navy and studied law, with a view to practising in the West Indies, and eventually managing his property in person. But a volcano destroyed the family estate, and he was thrown back upon his prospect of a legal practice in the West Indies. He entered Gray's Inn in 1813, and was called on Nov. 18, 1818. Godfrey Sykes, whose pupil he was, advised him to try his fortunes in England. He accordingly joined the home circuit and practised at the Surrey sessions, also buying the right to appear at the old palace court (*see* LORD STEWARD).

In 1824 he distinguished himself by his defence of Joseph Hunt when on his trial at Hertford with John Thurtell for the murder of William Weare; and eight years later at Chelmsford assizes he won a hard-fought action in an ejectment case after three trials, to which he attributed so much of his subsequent success that when he was raised to the peerage he assumed the title Lord Chelmsford. In 1834 he was made king's counsel, and in 1835 was briefed in the Dublin election inquiry which unseated Daniel O'Connell. In 1840 he was elected M.P. for Woodstock. In 1844 he became solicitor-general, but having ceased to enjoy the favour of the duke of Marlborough, lost his seat for Woodstock and had to find another at Abingdon. In 1845 he became attorney-general, holding the post until the fall of the Peel administration on July 3, 1846. Thus by three days Thesiger missed being chief justice of the common pleas, for on July 6 Sir Nicholas Tindal died, and the seat on the bench, which would have been Thesiger's as of right, fell to the Liberal attorney-general, Sir Thomas Wilde. In 1852 he became M.P. for Stamford. On Lord Derby coming into office for the second time in 1858, Sir Frederic Thesiger was raised straight from the bar to the lord chancellorship (as were Lord Brougham, Lord Selborne, and Lord Halsbury). In the following year Lord Derby resigned. Again in 1866, on Lord Derby coming into office for the third time, Lord Chelmsford became lord chancellor for a short period. In 1868 Lord Derby retired, and Disraeli, who took his place as prime minister, wished for Lord Cairns as lord chancellor. Lord Chelmsford died in London on Oct. 5, 1878. He had married in 1822 Anna Maria Tinling, and left four sons and three daughters, of whom the eldest, Frederick Augustus, 2nd Baron Chelmsford (1827–1905), earned distinction as a soldier, while the third, Alfred Henry Thesiger (1838–80), was made a lord justice of appeal and a privy councillor in 1877, at the age of 39, but died only three years later.

See *Lives of the Chancellors* (1908), by J. B. Atlay, who had the advantage of access to an unpublished autobiography of Lord Chelmsford.

CHELMSFORD, market town and municipal borough, and the county town of Essex, England, 30 mi. E.N.E. from London by the Eastern Region railway. Pop. (1938) 31,400. Area 7.4 sq.mi. It lies in the Chelmer valley at the confluence of the Cann, and has communication by river with Maldon and the Blackwater estuary, 11 mi. east. Chelmsford (*Chilmersford, Chelmeresford, Chelmsford*), owed its mediaeval importance to its position on the road from London to Colchester. It consisted of two manors: that of Moulsham, which remained in the possession of Westminster abbey from Saxon times till the reign of Henry VIII and that of Bishop's hall which was held by the bishops of London from the reign of Edward the Confessor to 1545. The mediaeval history of Chelmsford centred round the manor of Bishop's hall. Early in the 12th century Bishop Maurice built the bridge over the Chelmer which brought the road from London directly through the town, making it an important stopping place. The town was not incorporated until 1888. In 1225 Chelmsford was made the centre for the collection of fifteenths from the county of Essex and in 1259 it became the regular seat of assizes and quarter-sessions. The parish church of St. Mary is a Perpendicular building largely rebuilt. The grammar school was founded in 1551 by Edward VI. In 1316 the bishop obtained the grant of a weekly market and in 1221 that of an annual fair, now discontinued for four days from the feast of St. Philip and St. James. The town has a large agricultural market and a corn exchange in the centre of the square. There are agricultural implement and iron foundries, electrical and engineering works and extensive corn mills. There is a racecourse 1 mi. S. of the town. The see of Chelmsford, founded in 1914, includes the whole of Essex and part of Suffolk and Kent. At the former radio station there the first wireless telephone broadcasting service in the world was transmitted Feb. 23, 1920. The borough is in the Chelmsford parliamentary division of Essex.

CHELMSFORD, a town of Middlesex county, Massachusetts, U.S., adjoining the city of Lowell. It lies on both sides of the Concord river and on the Merrimack, and is served by the New York, New Haven and Hartford railroad. Pop. (1950) 9,303. It has numerous factories. Chelmsford was first mentioned in the records of the state in 1655. Lowell was set off in 1826.

CHELSEA, a western metropolitan borough of London, England, bounded E. by the city of Westminster, N.W. by Kensington, S.W. by Fulham, and S. by the river Thames. Pop. (est. 1938) 56,050. Area 1.9 sq.mi. Its chief thoroughfare is Sloane street running south from Knightsbridge to Sloane square. From Chelsea King's road leads west, a commercial highway, named in honour of Charles II and recalling the private road from St. James's palace to Fulham. The main roads south join with the Victoria or Chelsea, Albert and Battersea bridges over the Thames. The Chelsea embankment, planted with trees and lined with fine houses and, in part, with public gardens, stretches between Victoria and Battersea bridges. The residential portion is eastern Chelsea near Sloane street and along the river. Chelsea, especially the riverside district, has many historical associations. At *Cealchythe* a synod was held in 787. A similar name occurs in a Saxon charter of the 11th century and in Domesday; in the 16th century it is *Chelcith*. The later termination *ey* or *ea* was associated with the insular character of the land and the prefix with a gravel bank (*cf.* Chesil bank, Dorsetshire); but the early suffix *hythe* commonly means a haven. The manor was originally in the possession of Westminster abbey but its history is fragmentary until Tudor times. Henry VIII passed it to his wife Catharine Parr. It fell afterward to the Howards and the Cheynes, and later to the Cadogans. The memorials in St. Luke's (the old church) include those of Sir Thomas More (d. 1535); Lord Bray, lord of the manor (1530); Lady Jane Guyldeford (1555); Lord and Lady Dacre (1594-1595); Sir John Lawrence (1638); Lady Jane Cheyne (1668); Francis Thomas "director of the china porcelain manufactory, Lawrence Street, Chelsea" (1770); Sir Hans Sloane (1753); Thomas Shadwell, poet laureate (1692); Woodfall, the printer of *Junius* (1842), and many others. The church, which had never been "restored," was ruined in World War II, though the chapel built by More still stands. Happily, most of the fine monuments were rescued, many almost undamaged. In the 18th and 19th centuries Chelsea was a literary and artistic quarter. Atterbury and Swift lived in Church lane, Steele and Smollett in Monmouth house. Later, Turner, Rossetti, Whistler, Leigh Hunt, Carlyle (whose house in Cheyne row is preserved as a public memorial), Lord Courtney, Count D'Orsay and Isambard Brunel are connected with Chelsea. At Lindsey house Count Zinzendorf established a Moravian society (*c.* 1750). Sir Robert Walpole's residence was extant till 1810; and till 1824 the bishops of Winchester had a palace in Cheyne walk. Queen's (Tudor) house was the home of D. G. Rossetti.

Ranelagh (*q.v.*) in the second half of the 18th century, and Cremorne gardens (*q.v.*) in the middle of the 19th, were famous places of entertainment. Don Saltero's museum contained curiosities from Sir Hans Sloane's famous collections. Sloane gave the Apothecaries' company ground for the Physick garden, which ceased in 1902 to be maintained by the company. The original Chelsea bun-house, claiming royal patronage, stood until 1839, and one of its successors until 1888. The porcelain works existed for some 25 years before 1769, when they were sold and removed to Derby. Chelsea Royal hospital for invalid soldiers, initiated by Charles II and opened in 1694 is well known. A system of out-pensioning was found necessary from the outset, and it relieves large numbers throughout the empire. The picturesque building by Sir Christopher Wren the great hall of which was damaged during World War II stands in extensive grounds, which include the former Ranelagh gardens, site of the annual showing of the Royal Horticultural society. Crosby hall with new building adjacent to it, was opened in 1927 as a residence hall for university women. The hall, built by Sir John Crosby in Bishopsgate in 1466 was removed thence to a site on Sir Thomas More's former garden in 1910 to save it from demolition. The Chelsea public library contains an excellent collection relative to local history. Chelsea returns one member to parliament.

CHELSEA, a city of Suffolk county, Massachusetts, U.S., on a peninsula between the Mystic and the Chelsea rivers and its inlets, opposite the Charlestown and East Boston districts of the city of Boston, bounded on the west by the city of Everett and on the north by the city of Revere. It has 3 mi. of water front with 35 ft. channel depth on upper Boston bay; and is served by the Boston and Maine and the Boston and Albany railways. It is less than 1 mi. of Logan International airport. The 2 mi. Mystic River bridge, cantilever type, costing $27,000,000 was opened in 1950. The population in 1950 was 30,038, and in 1940 was 41,159 by the federal census.

The central part of the city was practically rebuilt after 1908 when on April 14 it was swept by a fire which destroyed one-third of the city, including most public buildings. Chelsea is primarily an industrial city with about 200 factories. Its industries include lithography, shoes, shoe cut stock and findings, car wheels, rubber heel and soles, bakery products, foundry and machine-shop products, smoked and dried fish, furniture, fluorescent lighting, automatic machinery, chemicals, prints, varnish and lacquers, wallpaper, elastic webbing, boxes, marine dock and creosote products. It is a centre for junk salvage, with dealers in many kinds of waste material, metals, rags, paper, burlap, rubber, automotive, etc. Bulk oil wholesale plants occupy a large portion of the waterfront. A U.S. naval hospital and the Massachusetts Soldiers' home and hospital are situated there.

The Cary-Bellingham house, once the palatial home of Governor Bellingham, is an excellent example of colonial architecture, and is preserved as a historical relic, open to the public.

Chelsea (called Winnisimmet until 1739) was settled in 1624 by Samuel Maverick, a prominent loyalist and churchman, the first settler on Noddle's island (East Boston). It was set off from Boston as a separate town in 1739, and was chartered a city in 1857. In May 1775, a British schooner, the "Diana," in the Mystic river was captured by colonial militia under Gen. John Stark and Israel Putnam.

CHELSEA HOSPITAL. The Royal Hospital, Chelsea, to give the institution its full title, was founded by Charles II. Tradition has it that Nell Gwynne moved the king to build the

...pital, but it is probable that the idea originated with Sir ...tephen Fox, who had been a paymaster general to the forces. ...r Christopher Wren was the architect, and the building was ...ressed in 1692. Many military trophies are preserved at the ...ital including the colours captured at Blenheim and Water... and there is a fine collection of medals and pictures in the ...reat hall.

The candidates for a Chelsea in-pension must be out-pension... *i.e.* in receipt of either a service, disability or campaign ...nsion. Candidates must be 55 years of age, unless through loss ...limb or other disability, the result of army service, they are ...nsidered eligible for admission to in-pension at an earlier date. ...e establishment of in-pensioners is 558. The candidates must ...capable of looking after themselves. In-pensioners may leave ...e hospital and revert to out-pension if they so wish but unless ...re are some exceptional reasons such men are not again ...itted to in-pension.

In addition to the in-pension establishment, the board of com...sioners administer long service pensions, special campaign ...and deal with disability pensions other than those aris...g from World War I and earlier wars, which are administered ...the ministry of pensions. They also approve, after investiga...the applications of pensioners who desire to receive a com...sum in lieu of a portion of pension for the purpose of ...se purchase etc. The number of men on the army pension list ...nistered by the commissioners of the royal hospital was in ... approximately 103,000.

CHELTENHAM, a municipal and parliamentary borough of ...cestershire Eng., abou. 96 mi W.N.W. of London. Pop. ... Area 8 sq.mi. The town lies where the Chelt, a ...tributary of the river Severn breaks the western escarp...t of the Cotswold hills. It is a residential holiday and sport... resort and is also visited for its medicinal waters. There are ...ine springs, the Pittville, Montpelier and Central spas. ...the 18th century a number of light industries were estab...ed in and around the town. Four miles west is Staverton air...

There was an early settlement at Cheltenham and a church ...ded there in 803. The manor belonged to the crown and was ...ted to Henry de Bohun, earl of Hereford, in the 12th century. ...ter it was bought by the abbey of Fécamp in Normandy and ...ently belonged to the priory of Corneille. In 1415 it was ...scated but at the dissolution it returned to the crown. It ...e became the property of the Dutton family. The town is first ...ioned in 1223, when the benefit of the markets fairs and ...ries of Cheltenham was leased to it for three years. Henry III ...newed the lease in 1226 and in 1230 granted a Thursday market ...three-day fair on July 24. It was governed by commis...ers from 1803 to 1876, when it was incorporated. It became ...parliamentary borough in 1832, returning one member. After ...discovery of the mineral springs in 1716 and the erection of ...pump room in 1738 Cheltenham rapidly became fashionable, the ...s of George III and the royal princesses in 1788 ensuring its ...ularity. As an inheritance of those times the town is graced ...many delightful Georgian building and wide tree-lined avenues ...open spaces. Gustav Holst was born at Cheltenham in 1874.

Cheltenham is a well-known educational centre, the principal ...titutions being Cheltenham college (founded 1841); Chelten...m Ladies' college (1853); Dean Close school (1886); a gram...r school (founded 1586; rebuilt 1883); and teachers' training ...leges. The town hall, the opera house and the civic play...se are used for entertainments. After World War II annual ...tivals of contemporary British music were launched. Race ...ting are held under National Hunt rules, and county matches ...e played on the cricket ground with an important cricket festival ...in Aug...

CHELYABINSK, a region and town in the Uralsk area of ...e Russian S.F.S.R. The region has an area of 62,741 sq.mi. ...p. (1939) 2,802,949; urban 1,181,871; rural 1,621,078. It is ...otted with forest, marsh and lake, but 59.2% is under cultiva... ...heat, oats, rye, millet, peas, etc.). Cattle, sheep, horses and ...pigs ...reared and coal is mined.

...are flour mills, brandy distilleries, breweries and other factories for food products. The town of Chelyabinsk, lat. 55° 8′ N., long. 61° 35′ E. pop. (1939) 273,127, is a trading centre for coal and Siberian grain. Manufactures of agricultural imple...ents and leather goods are carried on, and the town has an elevator and a radio station. It is connected by rail with the north through Sverdlovsk (formerly Ekaterinburg), with the east, as the beginning of the trans-Siberian railway, and with the west through Zlatoust and Ufa. It was founded in 1658. During the Civil War following the 1917 revolution Chelyabinsk was for a time the headquarters of the Czechoslovak legion and the scene of much internecine warfare.

CHELYS, the common lyre of the ancient Greeks (Gr. χέλυς, tortoise), which had a convex back of tortoise shell or of wood shaped like the shell. According to tradition Hermes was attracted by sounds of music while walking on the banks of the Nile, and found that they proceeded from the shell of a tortoise across which were stretched tendons which the wind had set in vibration (*Homeric Hymn to Hermes*, 47–51). The word has been applied arbitrarily since classical times to various stringed instruments.

CHEMICAL ACTION is said to occur whenever the properties of a substance are so completely altered that we are entitled to regard the product as a new and distinct substance. In the burning of coal, for example, a combustible, black solid is chemically changed by union with the oxygen of the air, to produce ash, water vapour and gases, all of which differ from the original coal in all their important properties. The chemist pictures the properties of every substance as being determined by the chemical make-up of its molecules: *i.e.*, by the nature of the atoms which are contained in each molecule of the given substance, and the manner of their arrangement. Thus water is different from carbon disulphide because the molecules of water contain atoms which are different from those contained in molecules of carbon disulphide, on the other hand the molecules of grape sugar (glucose) and fruit sugar (fructose) contain identical atoms in identical proportions but the properties of these substances are nevertheless different because the atoms are differently arranged in the two kinds of molecules. (*See* REACTION KINETICS.)

The complete change of properties which is associated with chemical action is therefore to be considered as being accomplished by the recombination or rearrangement of atoms to produce new sorts of molecules. The science of chemistry (*q.v.*) is mainly concerned with the study of chemical change. The details thus far accumulated are commonly presented in chemical textbooks under headings that correspond with the various individual elements. The general results and such principles as are generally applicable to chemical change, form the subject matter of physical chemistry (*see* CHEMISTRY: *Physical*), and of these the present article deals with a few which are related most intimately to the factors that determine how quickly a given chemical change may be accomplished.

CHEMICAL REACTION VELOCITY

The variation in the speed of chemical change and its dependence on the nature of the reacting substances is illustrated on the one hand by the almost instantaneous change (explosive reaction) which transforms a stick of dynamite into gaseous products, and on the other, by the very slow change by which a steel girder is converted into a pile of iron rust, a process which may require thousands of years. It will only be possible to explain why some changes proceed so rapidly and others with such extreme slowness when we are able to state the cause of chemical change in general. At present, we can merely conclude that this is caused by the action of electrical forces, the nature of which we are beginning to understand as the result of recent observations which have provided us with information concerning the inner structure of the atoms themselves. (*See* ATOM.) It usually happens, as Julius Thomsen (1854) and Marcellin P. E. Berthelot (1867) first emphasized, that rapid and energetic chemical reactions take place with the liberation of greater quantities of heat than sluggish reactions although this rule is subject to many exceptions.

A second factor determining the speed of chemical change is the concentration of the reactants. By this we mean the amounts

of the different reacting substances in unit volume. Thus C. F. Wenzel, in 1777, observed that metals dissolve in moderately concentrated acids more rapidly than they do in very dilute acids. Indeed it was soon recognized, as a result of the work of Claude Louis Berthollet in 1803, that whether a given chemical change or its reverse takes place sometimes depends only on the concentrations in which the several reacting substances are brought together In such instances the effect of concentration outweighs the effect of the nature of the reacting substances, loosely termed "chemical affinity." The earliest accurate observations of the effect of concentration on the velocity of chemical changes were made by L. Wilhelmy (1850), who showed that the rate of conversion of cane sugar into glucose and fructose in the presence of an acid is at every moment very nearly proportional to the concentration of the cane sugar. These observations constituted the first definite proof that the influence of the concentration of a reacting substance can be quantitatively stated, but did not lead to any generalized statement.

It is only in the simplest type of chemical change, in which the change may be accomplished with a single molecule of a given reactant, that the velocity of the change is proportional to the first power of the concentration of that reactant If n molecules of a reactant are required to accomplish the chemical change the velocity of the change is proportional to the nth power of the concentration of that reactant. In many cases n will be indicated by the chemical equation for the change. Thus $2H_2 + O_2 = 2H_2O$, indicates that the formation of water from hydrogen and oxygen demands two molecules of hydrogen for every molecule of oxygen, and thus that the rate at which water is formed at any given temperature is proportional to the first power of the concentration of oxygen but to the square of the concentration of hydrogen. In more complicated reactions, however, the chemical equation gives no clue to the power to which the concentration must be raised in calculating reaction velocity, for the chemical equation often expresses only the total effect and final result of a series of simpler consecutive chemical changes, the slowest of which determines the speed at which the series of changes as a whole may be accomplished. Changes in pressure are without effect on the velocity of chemical change, save in so far as pressure may determine concentration, as happens especially with mixtures of gases.

A third factor which affects the velocity of chemical change is the temperature. With rare exceptions, which can be readily explained, an increase of temperature increases the rate at which a chemical change will take place. Milk quickly turns sour on a warm day, and a mixture of hydrogen and oxygen, prepared safely enough at room temperature, explodes when it is heated by an electric spark. Commonly an increase of 1° C increases the velocity of a chemical change 10% or more, and most reactions at the temperature of boiling water proceed with several hundred times the velocity observed at room temperature. This striking effect of temperature is examined mathematically later.

A fourth factor is the presence or absence of particular substances which may increase or diminish the velocity of the chemical change, without being themselves permanently altered. Thus the velocity of a reaction between substances dissolved in water is different from the velocity of the same reaction, when the solvent is alcohol or benzene. Certain chemical reactions, including many of the most important in animals and plants, appear only to take place in the presence of these substances, which apparently need only be present in relatively small quantities. Changes of this sort are grouped under the head of catalytic action, or catalysis (*q.v.*); the substances essential to bring about the chemical changes between the reactants are called catalysts, or, in the case of the animal and plant ferments, enzymes (*q.v.*). The phenomena of catalysis and adsorption (*q.v.*) are closely connected with reaction velocity.

Finally, the velocity of a chemical change may be determined by the supply of energy to the reacting system from an external source. If this is light energy we have the phenomena of photochemistry (*q.v.*); if electrical energy, the velocity of the reaction will depend on the principles discussed under electrochemistry (*q.v.*), especially the laws of Faraday. The transformations of matter which occur in radioactive changes (*see* RADIOACTIVITY, NATURAL) differ from ordinary chemical changes in proceeding at rates which are determined entirely by the inner structure of the atoms of the radioactive elements, and are thus quite independent of the states of combination of those elements and even of the temperature.

CHEMICAL EQUILIBRIUM

Law of Mass Action.—We have referred to the observation of Berthollet that the concentration of the reactants is often sufficient to determine whether a given reaction or its reverse will take place. In this way we may explain why it so often happens that a chemical change fails to become complete, and comes to an apparent halt before the reacting material has been completely transformed. Evidently the forward reaction, transforming reactants A and B into resultants A′ and B′, is accompanied by a reaction which transforms A′ and B′ into A and B. Thus each reaction offsets the other, and the chemical change accordingly remains incomplete. The result is chemical equilibrium, commonly formulated with reversed arrows, thus:

$$A + B \rightleftarrows A' + B'$$

The proportions in which the different reactants are present in a mixture of substances which have attained a condition of chemical equilibrium are determined by a principle discovered by C. M. Guldberg and P. Waage in 1867. These investigators showed that the state of equilibrium attained in a reversible reaction can be interpreted on the assumption that the equilibrium state is the result of the equality of the speeds of the two opposed reactions, for each of which the velocity v or v' can be expressed in terms of a constant multiplied by the concentrations of the reacting substances, expressed by [A], [B], or [A′], [B′]. The velocities of the two opposed reactions are therefore given by $v = k\,[A].[B]$ and $v' = k'\,[A'].[B']$. At equilibrium these two velocities are equal, hence

$$k/k' = [A'][B']/[A][B] = K$$

in which K is the so-called equilibrium constant. If the reaction corresponds with

$$mA + nB \rightleftarrows m'A' + n'B',$$

the equilibrium constant may be written

$$K = \frac{[A']^{m'}[B']^{n'}}{[A]^{m}[B]^{n}}$$

The practical importance of a knowledge of equilibrium constants, calculated as just shown, will be realized when it is remarked that the equilibrium constant for any given reaction at a given temperature is independent of the concentrations in which the reactants are brought together. Thus when the numerical value of the constant has once been determined we may substitute this in the preceding equations, and determine the proportions in which the reactants and resultants will be intermingled when equilibrium is reached, starting from any given initial concentrations.

Though the mathematical expressions just given (commonly called mass-action expressions) may be regarded as empirical statements of actual laboratory experience with systems in chemical equilibrium, nevertheless they may readily be derived from the kinetic theory. It may be assumed in the simplest case that the interaction of two reactants A and B is the result of collision between the respective molecules. It follows that the rate of change should be proportional to the frequency with which such collisions occur The frequency with which a given molecule of A collides with molecules of B is proportional to the number of the latter in unit volume, *i.e.*, the molecular concentration of B; and in the same way the frequency of the collisions between a given molecule of B and the molecules of A is proportional to the molecular concentration of the latter. The total number of collisions between the molecules of A and B is therefore proportional to the product of the molar concentrations.

Kinetic considerations thus led to $v = k[A][B]$ which is the expression for the reaction velocity, embodied in mass-action expressions above. The coefficient k in this formula is called the

specific reaction rate, and represents the velocity when the concentrations of the two reacting substances are each equal to unity. It depends on the nature of the reacting substances, the temperature, and the medium (solvent) in which the reaction occurs. In the case of gaseous reactions there is no solvent to be considered, but it may be noted that many apparently gaseous reactions are in reality surface reactions, *i.e.*, reactions which take place largely, if not entirely, on the surface of the walls of the containing vessel. (*See* ADSORPTION.)

Influence of Temperature on Reaction Velocity.—The principal weakness of the explanation which makes chemical change depend solely on collisions between molecules, is that the velocity should be approximately the same for all reactions of the same type under like conditions of temperature and concentration. Actually rate of chemical change is a highly specific quantity, which varies widely from one reaction to another. Moreover, if we conceive of reaction rate as depending altogether on the frequency of collisions between molecules, we find it impossible to account for the extraordinary influence of temperature on reaction rate. In the simplest cases, an increase of temperature of 10° C. would speed up the molecules sufficiently to make collisions between them several per cent more frequent, whereas reaction velocity in that temperature range is actually increased several hundred per cent. The simplest way of explaining this involves the assumption that molecular collision is not always followed by chemical change. Collision between molecules, when reactants A and B are transformed into resultants A′ and B′, is a necessary but not sufficient condition for reaction.

We have then to account for the fact that the proportion of the colliding molecules which react grows rapidly larger as the temperature is increased. We might assume that reaction takes place only when molecules collide that happen to have velocities exceeding some stated critical velocity Yet the proportion of such molecules, calculated from Maxwell's law of distribution of velocities, does not increase with increasing temperature in a way that fits the experimental facts.

Actually, as was first pointed out by Svante Arrhenius (1889), the specific reaction rate k for many common reactions varies with the temperature in a way that may be explained by assuming that only a very small proportion of the molecules are in a condition to react on collision. In other words the vast majority of collisions do not result in chemical change but this only takes place when the energy content of the colliding molecules is much greater than the average. The proportion (α) of the effective collisions increases rapidly with the temperature and if the extra energy (energy of activation) required at the absolute temperature T is represented by q, then the empirical relation of Arrhenius for the connection between reaction velocity and temperature may be put in the form

$$d\ln\alpha/dT = q/RT^2 \quad \text{or} \quad \alpha = e^{-q/RT}$$

At a given temperature, the value of α thus depends on the magnitude of q and diminishes as q increases. When the concept of active molecules is incorporated in the mass action equation, this becomes

$$v = k \cdot e^{-q/RT} \cdot [A] \cdot [B]$$

in which q represents the extra energy of the impact which is required for the collisions between molecules of A and B to be effective.

This discussion neglects the possibility that even molecules possessed of the requisite supply of energy may not react when they collide unless they happen to be disposed in favourable positions with respect to each other at the moment of collision. A collision between molecules of ethyl alcohol and acetic acid, for example, would not be expected to produce a molecule of ethyl acetate unless the hydroxyl and carboxyl groups are favourably placed when collision takes place. Neglecting this difficulty, the coefficient k can be evaluated in terms of specific and general constants and the equation for the bimolecular reaction becomes

$$v = N\sigma^2\sqrt{[8\pi RT(1/m_A + 1/m_B)]} \cdot e^{-(q^A+q^B)/RT} \cdot [A] \cdot [B]$$

in which N is the Avogadro number (6×10^{23}), σ is the mean diameter of the molecules and m_A and m_B are the molecular weights of A and B. This equation, due to W. C. McC. Lewis (1918) does actually enable us to calculate certain reaction rates with an accuracy which is satisfactory in view of the fact that the effective diameter of the colliding molecules is known only very roughly.

Unimolecular Reactions.—The assumption embodied in the preceding discussion, that chemical change occurs when molecules collide which happen to be possessed of a more-than-average supply of energy, at once meets the difficulty that many reversible reactions are known in which collisions between molecules appear to play no part. Thus when phosphorus pentachloride dissociates, forming phosphorus trichloride and chlorine, according to the equation $PCl_5 \rightleftarrows PCl_3 + Cl_2$, each molecule of PCl_5 would seem to decompose independently of other molecules in accordance with the ordinary law of chance. By some chemists it has been asserted that such chemical changes (called unimolecular reactions) are not really possible. The fact that they seem to be of frequent occurrence is presumed to be explained by the presence of traces of foreign substances, which, in acting as catalysts, provide the means for interpreting the mechanism on the basis of molecular collisions.

Recent work would, however, seem to have definitely established the occurrence of noncatalyzed gaseous reactions which proceed in accordance with the requirements of the unimolecular type of change over a wide range of concentration. An explanation of these has been sought in the radiation hypothesis, according to which the cause of the reaction is to be found in the selective absorption of radiant energy. The mechanism of the photochemical change would on this view by extended to all types of chemical reaction (*see* PHOTOCHEMISTRY). The wave length of the active radiation can be derived from the heat of activation of the molecules by Planck's relation, $q = h\nu$ (*see* QUANTUM MECHANICS), but in general the reacting substances afford no evidence of the requisite absorption bands. For this and other reasons the radiation hypothesis cannot be said to be acceptable. For a fuller discussion see *Trans. Faraday Soc.* (1922).

On the other hand, it seems probable that the apparently unimolecular reactions are primarily the result of molecular collisions, for it is only necessary to assume that the molecules activated by collision are for the most part deactivated by further collisions before they have time to reach that particular internal phase which is essential for chemical change to occur and the observed facts can be readily accounted for.

Since the molecules of the reaction products are the result of collisions between active molecules of the reactants and therefore, in general, distinguished by a high energy content, it follows that such "hot" molecules may hand on their excess of energy to other molecules of the reactants leading to a so-called chain reaction. Such chain reactions constitute a type which is illustrated by the combination of hydrogen and chlorine.

Chemical Activity.—Reference may now be made to the results which have followed from the application of thermodynamics to the problems of chemical action. Although the time factor is alien to the processes with which thermodynamics is concerned, the arguments peculiar to this branch of analysis can of course be applied to the states of equilibrium which are finally attained in reversible reactions. If the reacting substances are ideal gases (or solutes) thermodynamic reasoning leads to results which are identical with the expression for the law of mass action which follows from the kinetic theory. When the substances are not ideal, thermodynamics leads to the conclusion that the concentration terms in the mass-law expression should be replaced by the corresponding activities. The activity or effective concentration a of any substance is defined by the relation $\Delta F = RT \log a/a_0$, in which ΔF is the diminution of free energy associated with the reversible transformation of the substance from the condition defined by a to a standard condition defined by a_0. The activity in the standard condition may conveniently be taken as unity.

In practical applications the attempt is made to calculate activity or effective concentration by multiplying the actual concentration c, for the given substance, by an activity coefficient,

f, which is itself a function of the concentration. Then by substituting $a=fc$ for c, in the mass-action expressions given above, more nearly constant values for the equilibrium constant are found than would otherwise be obtained. To be fully satisfactory, this method would require that the activity coefficient, f, by means of which actual concentrations are converted into effective concentrations, should be independent of the nature of the reaction in which the given substance takes part. This has been found not to be the case. Accordingly J. N Brönsted has introduced the assumption that the interaction of two substances A and B involves the intermediate formation of a "collision complex" X and this leads to $v=kc_A c_B f_A f_B/f_X$ where f_X is the activity coefficient of the complex In this connection it may be noted that the activity coefficients of ions depend largely on their charges and on the ionic strength of their environment. (Ionic strength is calculated by taking half the sum of products formed by multiplying the concentration of each cation or anion in the solution by the square of its valence.) In accordance with the theory of P Debye and E. Hückel, the relation may be expressed in the form $-\log f=0.5x^2\sqrt{\mu}$ where x is the valence of the ion concerned and μ is the ionic strength of the solution in which it is present. This relation, when combined with Brönsted's reaction-velocity formula, affords results for ionic reactions of varied types which are in accord with experimental observations provided that the solutions are sufficiently dilute.

IONIC THEORY

Relative Strengths of Acids and Bases.—Although much recent work has been concerned with the precise significance of "active mass," the classical interpretation of this as synonymous with molecular concentration has yielded results of the greatest importance in the interpretation of the manifold phenomena associated with aqueous solutions of acids, bases and salts (*see* Solution). Such substances are, in general, electrolytic conductors, and in accordance with the theory of Arrhenius are ionized to a greater or less extent. The traditional view, that salt formation corresponds with the neutralization of opposite qualities which characterize the acids and bases respectively, finds simple expression in the ionic theory, for according to this, acids are substances which increase the hydrogen-ion concentration of water, while bases have the opposite effect. In aqueous solutions, the concentration of the hydrogen ion is directly connected with the hydroxyl-ion concentration, by the mass-action expression

$$K=\frac{[H^+].[OH^-]}{[H_2O]}$$

In all dilute aqueous solutions however the concentration of the un-ionized water $[H_2O]$ is nearly constant (55.5 moles per litre). Accordingly in all dilute aqueous solutions, whether acid, alkaline or neutral, the product of the two ion concentrations has a nearly constant value (10^{-14} at 25° C.). In neutral solutions hydrogen-ion (sometimes called hydrion) and hydroxyl-ion are present in equal concentrations 10^{-7} gram-ions per litre at 25° C.). In acid solutions the concentration of hydrogen-ion exceeds that of hydroxyl-ion; in alkaline solutions the reverse is true. Yet hydroxyl-ion is never completely absent from acid solutions, nor hydrogen-ion from alkaline solutions, for the concentrations of the two ions must always be so related that the ion product, $[H^+].[OH^-]$ has the constant value 10^{-14}, at 25° C. At higher temperatures the ion product increases very rapidly, attaining a value of about 60×10^{-14} at 100° C.

Equivalent solutions of different acids show very great differences in the hydrion concentration. These are exhibited very clearly when the electrical conductivities of such solutions are compared or when a comparison is made of the velocities with which certain reactions take place when these are subjected to the catalyzing influence of the various acids. The two series of numbers show a close parallelism which finds a simple interpretation in terms of the view that the differences between the acids are primarily caused by differences in their respective degrees of ionization. The conductivity is indeed proportional to the concentration of the ionized fraction of the acid and the catalytic effect is determined for the most part by the hydrion concentration. The application of the mass law to the equilibrium between the un-ionized acid and the corresponding ions, as represented by

$$HA \rightleftarrows \overset{+}{H} + \overset{-}{A}, \text{ gives}$$

$$K=[\overset{+}{H}][\overset{-}{A}]/[HA]=(c\alpha)^2/c(1-\alpha)=c\alpha^2/(1-\alpha)$$

for the ionization constant, c being the molar concentration of the acid and α the fractional degree of ionization. In spite of the charges on the ions, this relation between the concentration of the acid and its degree of ionization is in very close agreement with the actual behaviour of weak or slightly ionized acids, as was clearly demonstrated by Wilhelm Ostwald. The results obtained in this connection constitute in fact the strongest and most comprehensive evidence as yet available in favour of the quantitative application of the law of mass action to states of equilibrium. The Ostwald dilution law does not hold for solutions of salts or more active (largely ionized) acids or bases Many chemists have indeed arrived at the conclusion that most salts are completely ionized, at all concentrations. (*See* also Hydrogen-Ions.)

Neutralization of Acids by Bases.—In the neutralization of an acid by the gradual addition of a base, the essential reaction consists in the combination of hydrogen ions with hydroxyl ions until the concentration of both reaches the value for pure water, viz., 10^{-7} gram-equivalents per litre (25°), which condition is shown by suitable indicators (*q.v.*). The constancy of the heat of neutralization of the strong acids by the strong bases is explained in this way. If one equivalent of a base BOH is added to a solution which contains one equivalent of each of two different acids HA_1 and HA_2, the relative proportions of the two acids which are neutralized afford a measure of the so-called relative affinities of the acids for the base. Because of such differences stronger acids tend to displace weaker acids from the corresponding salts. Such displacement effects, however, are not always the result of a difference in the affinities of the acids, for complications may occur in consequence of the removal of one of the resultant substances from the sphere of action in the form of an insoluble solid or a volatile gas; *e.g.*, the displacement of nitric acid by the relatively very weak acid hydrogen sulphide in accordance with $2AgNO_3 + H_2S \rightarrow Ag_2S + 2HNO_3$ is directly due to the insolubility of silver sulphide. The basic affinities of a pair of acids can in fact only be derived from a determination of the relative amounts which are neutralized by a base when the system is homogeneous. If x is the fraction of the acid HA, which is neutralized by the base, BOH, in the above solution, the resulting equilibrium can be represented by

$$(1-x)HA_1 + (1-x)BA_2 = xBA_1 + x\text{-}HA_2,$$

and the evaluation of x, which can be effected by a variety of physical methods, gives up the ratio $x/(1-x)$ which expresses the affinity of HA_1 relatively to HA_2. When such affinity values, referred to an acid chosen as standard, are compared, it is found that the acids form a series which is essentially the same as the series given by the relative conductivities and catalytic activities. It can be shown that this experimental result is generally consistent with the hydrion theory of acids for the application of the mass law to the equilibria which are involved in the above mentioned competition of two acids for a base shows that the affinity ratio $x/(1-x)$ is the ratio of the degrees of ionization of the two acids. The fact that $x/(1-x)$ is independent of the nature of the base is also explained at the same time. Similar considerations apply to the relative strengths of bases. At a given concentration their characteristic properties can be explained in terms of the hydroxyl-ion concentration. Since degrees of ionization vary with the concentration, it is convenient to eliminate the latter. This can be done by comparing the strengths of acids and bases in terms of the respective ionization constants.

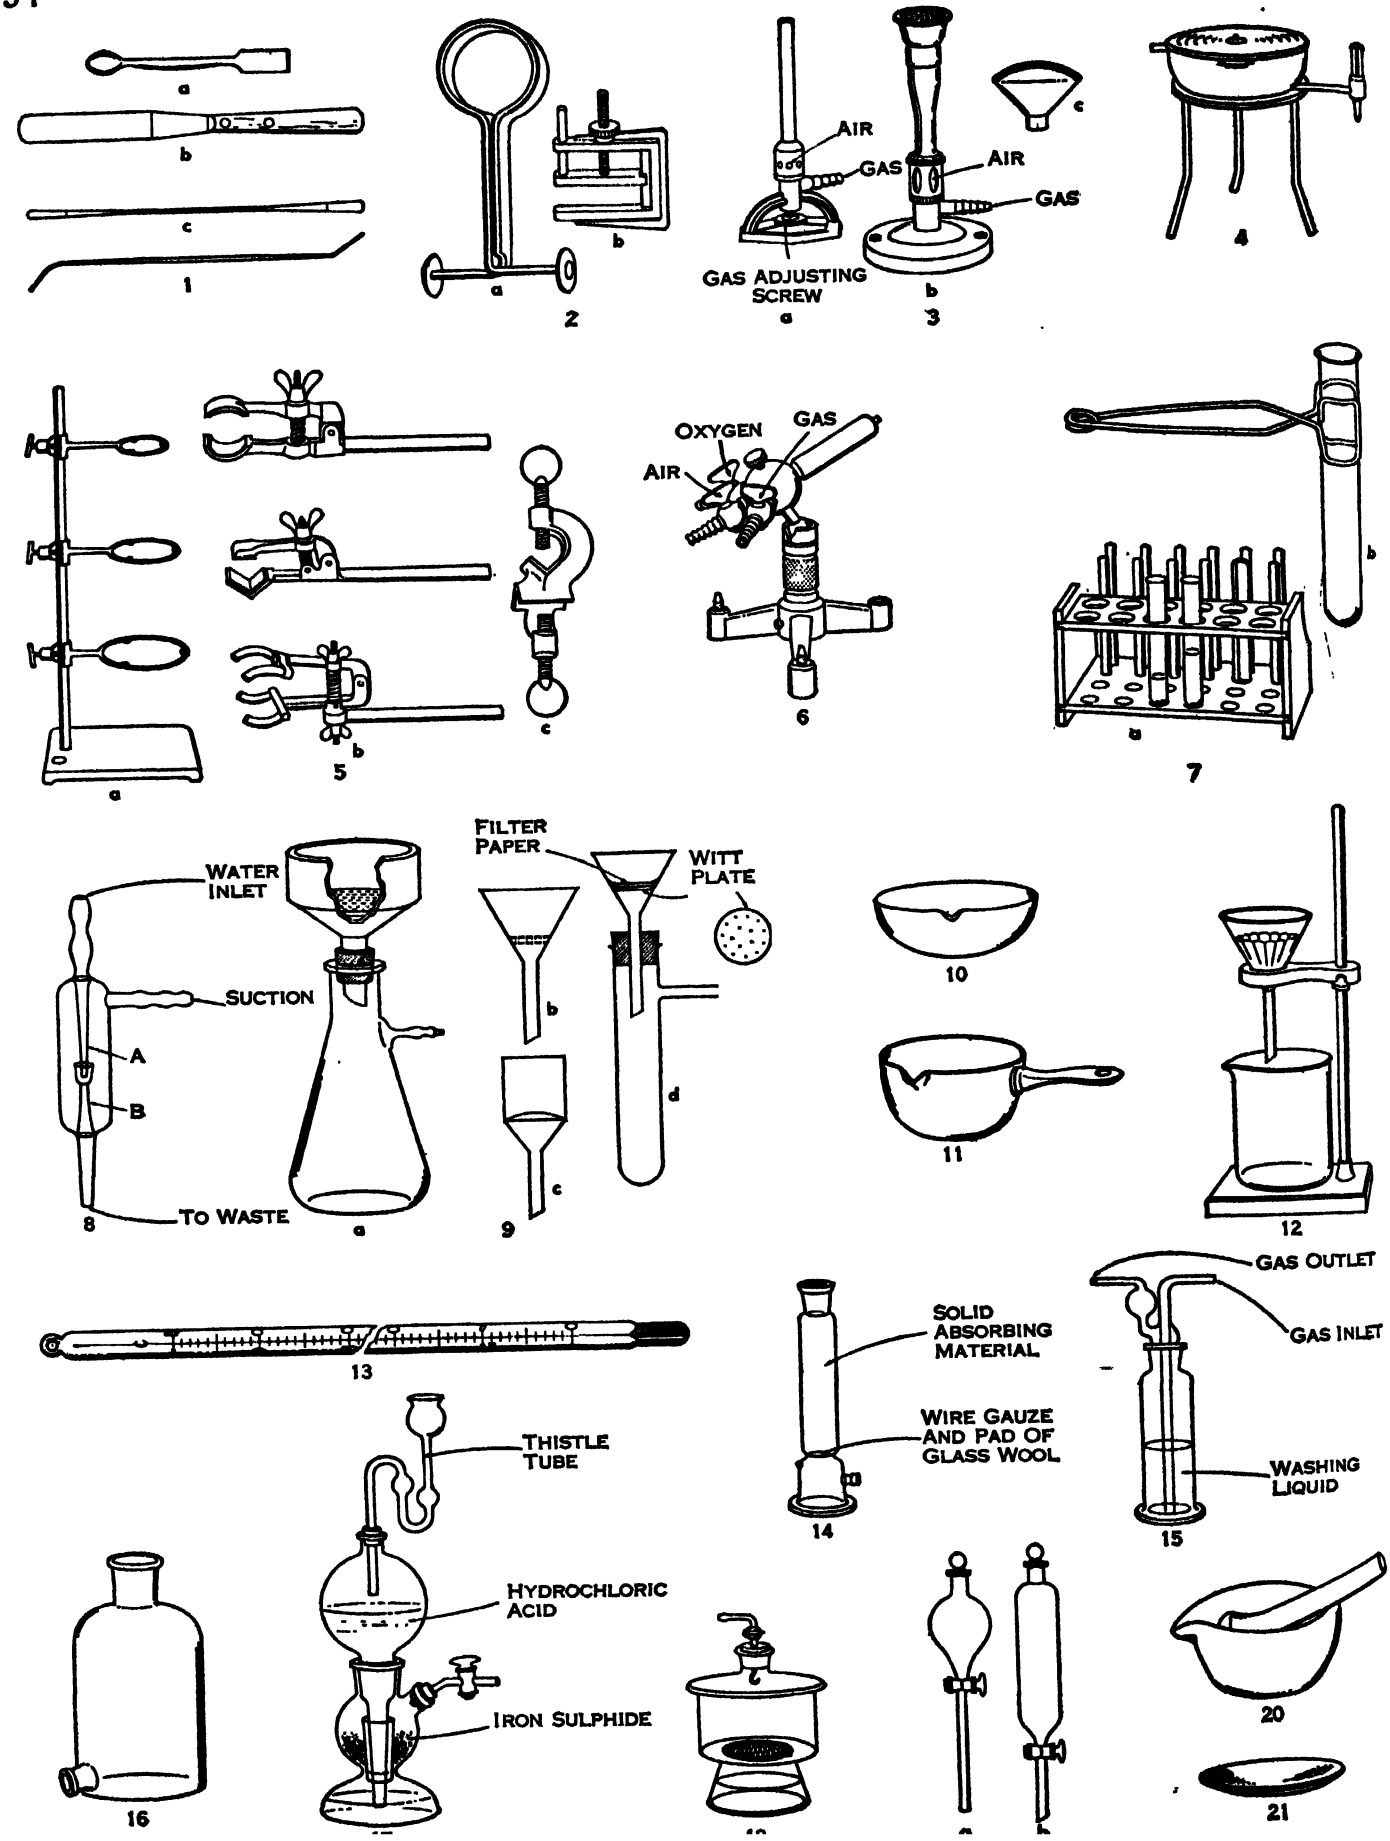
CHEMICAL APPARATUS. Chemical laboratory operations deal with gases, liquids and solids, and require for their manipulation a variety of specialized apparatus. Many of these find their counterpart in the home, since some of the unit operations such as heating, cooling, solution, etc., are a necessary part of our daily life. There is no fundamental difference between the laboratory Bunsen or Meker gas burner and the burner on the conventional kitchen gas-range. Frequently, the chemist may use the same glassware for a chemical manipulation that is used for baking or cooking in the home kitchen. In general, however, he must conduct his work with great care, as in analytical chemistry. The reagents are often corrosive and may be subjected to extremes of temperature or pressure, so that over a period of many years there has been devised a large number of items to facilitate chemical tasks.

Since chemical reactions can take place in the solid, liquid or gaseous phase a considerable proportion of laboratory apparatus is devoted to the processes of solution, extraction, filtration, precipitation, evaporation, distillation and desiccation. For these purposes flasks, beakers, suction pumps, suction flasks, water-baths, funnels, fractionating columns and stills are employed. Gases are conveniently manipulated in drying towers, aspirator pumps, gas generators, wash bottles and connections of glass tubing including stopcocks. Typical analytical chemical apparatus illustrated below includes crucibles, weighing bottles, burettes or burets, pipettes, graduates and graduated flasks.

Different pieces of apparatus may be connected with glass, rubber or plastic tubing. Stoppers of rubber or cork are used to make renewable seals at certain points such as thermometer inserts or connections between tubes. There is available a complete selection of glass apparatus such as flasks, condensers, columns and stopcocks comprising units of various sizes which fit together with either standard taper or hemispherical (semiball) joints to form gas-tight and liquid-tight seals. Since this glassware may be arranged at will to perform a large variety of unit operations it is gradually supplanting cork and rubber stopper closures in the more advanced laboratories. In order to ensure uniformity between the products of several manufacturers the United States bureau of standards has established tolerances for these joints and certifies master joints of steel for their checking. Both types of joints may be lubricated with rubber-petrolatum or synthetic ("Silicone") greases to render the joints completely gas-tight.



Physical measurements are an important part of laboratory practice and a chemical laboratory may employ a variety of measuring instruments. Mercury or liquid-in-glass thermometers, bimetallic thermometers, resistance thermometers and thermocouples are used for temperature measurement, whereas mercury or other fluid manometers and Bourdon gages are used to measure pressures. The chemical balance is used for weighing and it is constructed in many modifications depending upon the capacity and sensitivity demanded. The spectroscope (*see* SPECTROSCOPY) or spectrograph measures either the absorption or emission of light, and the colorimeter is used for exact colour comparison as in analytical determinations. Electrical measurements form the basis for the determination of hydrogen-ion concentrations (*q.v.*) using the *p*H meter, and reduction potentials are charted by the polarograph. Electrometric titrations as well as dyestuff indicators serve to determine the end-point in analytical titrimetry while burettes are available to measure amounts of liquids as small as $\frac{1}{1000}$ ml. with analytical accuracy. The index of refraction of light determined with the refractometer furnishes a useful guide to the purity and identity of chemical compounds, while the microscope makes it possible to manipulate and to observe beyond the capacity of the unaided eye. (*See* CHEMISTRY: *Analytical Chemistry*.)

Laboratory technique is constantly being refined and improved. For the manipulation of a few milligrams of scarce or valuable material there has been developed a group of miniature beakers, flasks, funnels, etc., which is called microchemical equipment. Although some of these are merely small-scale models of the larger apparatus, others are truly novel in design and are cleverly adapted to ultra-precise work. A few of these are illustrated below.

The following list refers to the accompanying illustrations of apparatus commonly used in a chemical laboratory.

General Apparatus

1. Spatulas and spoons, for dealing with small quantities of material without touching by hand. They may be made of (*a*) porcelain, (*b*) steel, (*c*) silver or other corrosion-resistant materials.
2. (*a*) Pinchcock or spring clip (Mohr's pattern). (*b*) Screw clamp or clip (Hoffmann).
3. (*a*) Bunsen burner (Tirrill type) with adjustable gas and air flow. (*b*) Meker burner for producing an intense flame over a broad area. Used for heating crucibles to high temperatures. (*c*) Wing-top which slips onto top of Bunsen burner to form "fish-tail"-shaped flame.
4. Water-bath and rings on tripod. The bath is nearly filled with water which is heated by a burner underneath. Removal of one or more of the rings enables any circular vessel (*e.g.*, an evaporating basin) to rest in the hole of appropriate size, and its contents are slowly heated or evaporated. A constant-level device maintains the level of the water in the bath and obviates refilling.
5. (*a*) Support with iron rings, (*b*) clamps and (*c*) clamp fastener (boss).
6. Blast lamp or blast burner. Separate valves are provided for controlling the flow of oxygen and air which are mixed and fed to the gas through a central tube. The gas issuing from the outer sleeve forms a brush flame or a fine-pointed flame depending upon the adjustment of the mixture.
7. (*a*) Test-tube stand and test tubes. (*b*) Spring-clamp test-tube holder.
8. Water-jet suction pump, for use with filter flask and either Büchner funnel (fig. 9) or Gooch crucible (fig. 33). The stream of water is broken up at the jet A and entrains air in its passage down the tube B. This is capable of reducing the pressure as low as the vapour pressure of water.
9. Apparatus for filtering by suction. (*a*) Büchner funnel fitted with a cork or rubber stopper into a filter flask which is attached to a suction pump (see fig. 8) by means of rubber tubing. A circle of filter paper is placed on the perforated bottom and the material retained by it can be sucked dry, washed and pressed. (*b*) Hirsch funnel. (*c*) Sintered-glass funnel. (*d*) Ordinary funnel.
10. Evaporating dish or basin (porcelain or glass).
11. Casserole (porcelain).
12. Filter stand, funnel and beaker for gravity filtration. A filter paper is folded so as to fit into the funnel as shown; it retains solids while liquids filter into the beaker.
13. Mercury in glass thermometer. Numerous scales are available for both higher and lower temperature ranges.
14. Drying tower. Similar in function to fig. 15, but used where gases have to be passed through a granulated solid.
15. Wash-bottle for gases (Drechsel pattern). If the gas is bubbled through the liquid it can be freed from one or more impurities, *e.g.*, it can be dried by passage through concentrated sulphuric acid, or freed from carbon dioxide by a solution of sodium hydroxide.
16. Aspirator bottle. A cork carrying a tube is inserted into the top opening while a stopcock may be attached to the lower opening and the bottle is filled with water. On opening the stopcock, water will flow out and this will draw air through the tube which may be attached to any other apparatus.
17. Kipp gas generator. Hydrochloric acid (HCl) is allowed to run down the central tube and rise so as to act on the iron sulphide; if the tap is open hydrogen sulphide gas (H_2S) is expelled by the pressure of the "head" of acid; when the stopcock is closed the gas forces the acid into the top bulb and no more gas is produced. If marble (calcium carbonate) is used instead of iron sulphide, carbon dioxide (CO_2) is obtained. It may also be used to generate hydrogen gas by zinc metal and dilute sulphuric acid.
18. Desiccator. Concentrated sulphuric acid, granular calcium chloride or other desiccant is kept in the bottom; the material to be dried is spread on a watch-glass or evaporating dish resting on the gauze or on a perforated porcelain plate. An accelerated drying effect is produced by evacuating the desiccator through the stopcock tube by means of the suction pump shown in fig. 8.
19. Separatory funnels: (*a*) pear-shaped—also called a dropping funnel; and (*b*) cylindrical. If ether has been used to extract an organic substance from water, two layers are formed and the lower (aqueous) layer can be run off. Similarly, if chloroform had been used instead of ether, the lower layer would be the chloroform extract.
20. Pestle and mortar (of porcelain).

FIGS. 1–21.—COMMON CHEMICAL APPARATUS (THE NUMBERS REFER TO DESCRIPTIONS IN THE TEXT)

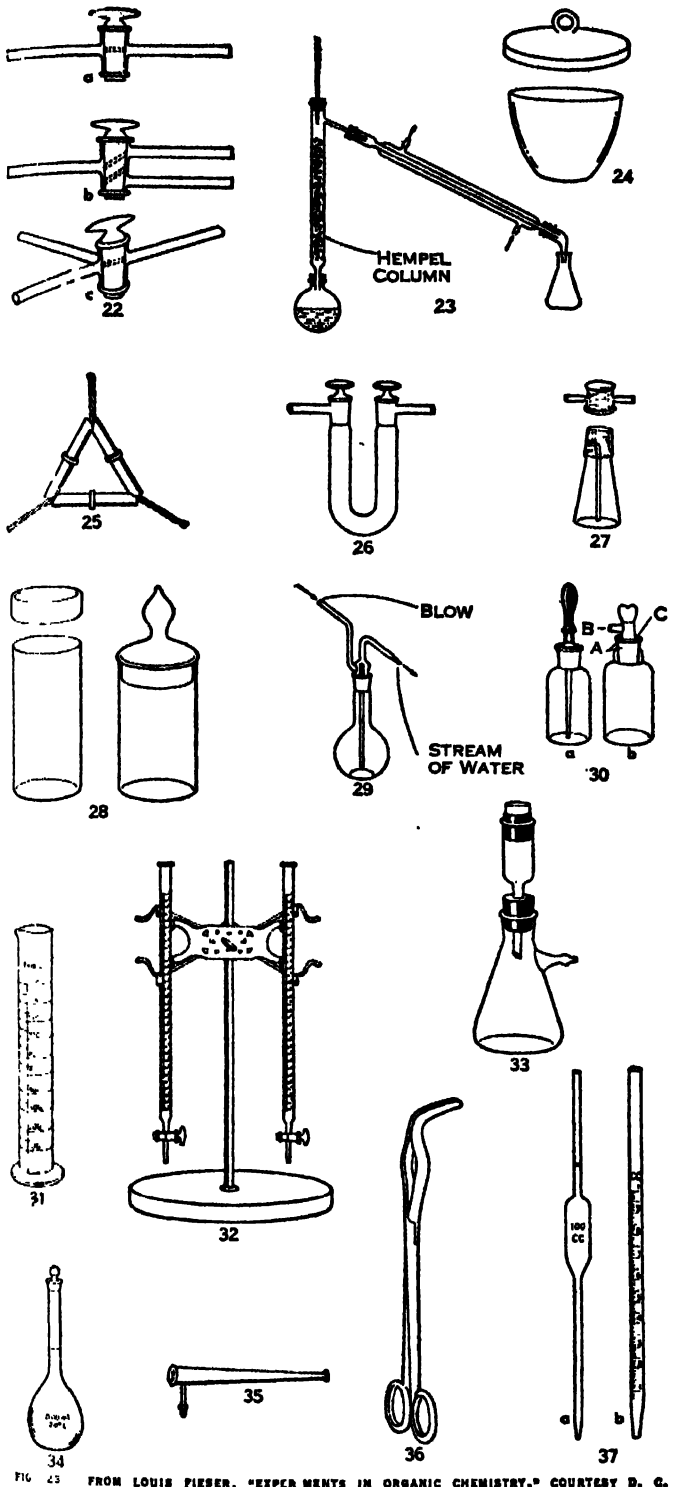

FIG. 23 FROM LOUIS FIESER, "EXPERIMENTS IN ORGANIC CHEMISTRY," COURTESY D. C. HEATH & COMPANY

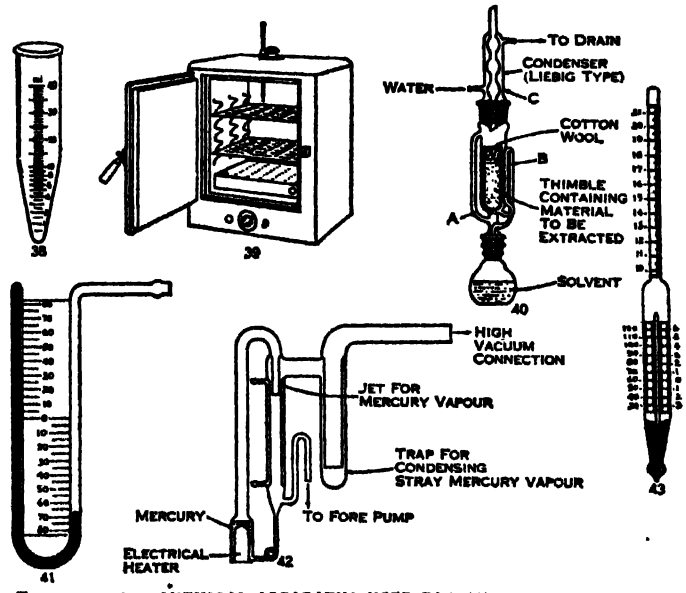
FIGS. 22–37.—CHEMICAL APPARATUS USED FOR ANALYSIS



21. Watch-glass for covering beakers while evaporating liquid. It is usually supported on glass U-shaped rods hung on the edge of the beaker.
22. Stopcocks or taps. (*a*) A half turn shuts off the flow. (*b*) Three-way oblique bore plug. A half turn connects the lower limb with the left hand tube. (*c*) T-bore stopcock.
23. Distillation with a fractionating column. The liquid in the round-bottom flask is boiled and the vapours pass through the column where partial condensation occurs. The reflux liquid washes the ascending gases which then pass into water-cooled condenser where they are condensed to a liquid. A thermometer indicates temperature of the condensing liquid and an adapter leads to receiver which is an Erlenmeyer flask.

Apparatus Used in Analysis

24. Crucible and lid made of porcelain, quartz or platinum. Used for igniting precipitates.
25. Clay triangle for supporting crucible on tripod or ring.
26. U-tube. May be filled with granulated soda-lime to absorb carbon dioxide, or with pumice soaked in sulphuric acid to absorb water vapour. The ground-in stopcocks can be turned to shut off connection with the outer air.
27. Absorption bulb (Turner). Used for the absorption of carbon dioxide formed by the combustion of steel in oxygen. The stopper may be rotated so as to close both openings after the combustion has been completed.
28. Weighing bottles, for protecting material from the air while it is being weighed. A portion of the contained substance is shaken out and the whole reweighed, the amount of material thus taken being the difference in weight.
29. Wash bottle. A fine stream of water (or organic solvent) can be directed where required.
30. Dropping-bottles. (*a*) By slightly pressing the rubber nipple and releasing the pressure, a few drops are drawn up in the glass tube and can be squeezed out one at a time when the nozzle is withdrawn. (*b*) Liquid flows along the capillary tube at A when the bottle is tilted, and a drop falls from B, air entering through another channel at C. Used chiefly for indicators (*q.v.*).
31. Graduate or measuring cylinder.
32. Burettes in stand. Used for titrations. The volume of liquid delivered is accurately read on the graduated scale (*see* CHEMISTRY: *Analytical Chemistry*).
33. Gooch crucible with rubber cone, glass adapter and filter flask. The bottom of the crucible is perforated with small holes, and a mat of asbestos is formed on it by pouring in a pulp of asbestos and water, sucking it nearly dry and completely drying it in the oven. Used for filtering, washing, drying and weighing precipitates.
34. Volumetric flask. Contains the stipulated volume when filled to the mark with a liquid at 20° C., the temperature at which it was calibrated. Used for preparing "standard" solutions, *i.e.*, solutions containing a definite quantity of solid dissolved in an exact volume of solution.
35. Mouth blowpipe; used for directing a small flame jet onto the substance being analyzed (usually supported on a block of charcoal).
36. Crucible tongs; may be tipped with platinum for refined work.
37. Pipettes (not to scale). (*a*) If filled exactly to the mark by suction it will then deliver the stipulated volume on draining for 15 sec. after continuous flow has ceased. (*b*) Can be used for gradual addition of small quantities which are read off on the scale.
38. Graduated conical centrifuge tube for measuring small volumes of centrifuged solid or liquid at the bottom.
39. Electrically heated oven with thermostatic control for drying precipitates to constant weight.

Special Apparatus

40. Soxhlet extractor. The material to be extracted is placed in a "thimble" of filter paper. Ether or other volatile solvent is boiled in the flask and passes through the side tube A to the reflux condenser C. The condensed liquid drops into the thimble where it accumulates until it reaches the level of the top of the side arm B, and then siphons over into the flask. Several complete cycles are permitted to occur before the

FIGS. 38–43.—CHEMICAL APPARATUS USED FOR ANALYSIS AND SPECIAL APPARATUS

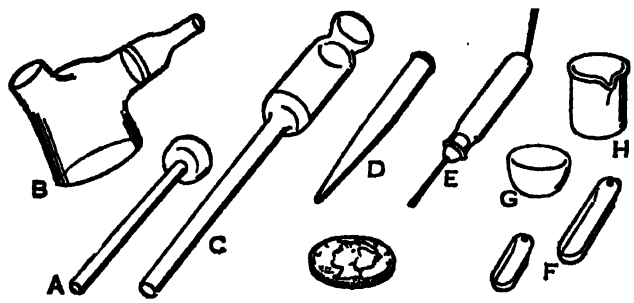


FIG. 14.—MICROCHEMICAL EQUIPMENT

Shown in size relationship to a ten-cent piece are: A. Porcelain filter stick for sucking liquids away from solids. B. Microfilter beaker. C. Sintered glass funnel. D. Microcentrifuge tube. E. Weighing tube (for protecting sample in boat from air during weighing. F. Microcombustion boats (small and medium size). G. 1-ml. porcelain crucible. H. 1-ml. glass beaker.

solvent flask is disconnected and the solvent evaporated to leave the extracted material.

41. Mercury manometer for vacuum distillations. The left-hand tube is completely filled with mercury as shown. When the side tube is connected to a system being evacuated the level in the left-hand tube drops while that in the right-hand tube rises, and the difference in height between the tops of the two mercury columns indicates the pressure in the system in millimetres of mercury.
42. Mercury vapour diffusion pump for producing high vacuum. The high velocity jet of mercury vapour permits diffusion of the other gases in the system into it. These are then removed by the fore pump after condensing the mercury in the condenser.
43. Hydrometer for determining the specific gravity of liquids. The instrument is floated in the liquid and the point on the scale in the stem coinciding with the surface level of the liquid indicates the specific gravity compared with water. A thermometer in the lower portion indicates the temperature of the liquid at the same time. Usually the liquid is brought to some specified temperature before the specific gravity is determined.
44. Microchemical equipment. (E. B. Hg.)

CHEMICAL ARTICLES. The main article CHEMISTRY includes a general survey of the *History of Chemistry*, and also deals comprehensively with the various branches of this science; viz., *Inorganic, Organic, Physical* and *Analytical Chemistry*. These and their practical applications are treated in fuller detail in the chemistry articles appearing in this encyclopaedia. There are articles elucidating fundamental ideas and definitions and explaining chemical changes; *e.g.*, ACIDS AND BASES; ATOM; COMBUSTION; ELEMENTS, CHEMICAL; MOLECULE, CHEMICAL; OXIDATION AND REDUCTION; REACTION KINETICS. ATOM: *Atomic Weights* contains a list of the elements; these are described, with their chief compounds, in separate articles. There are also separate articles on the more important compounds, *e.g.*, AMMONIA. The compounds of carbon, apart from the simple ones treated under the separate headings (such as CARBONIC ACID AND CARBONATES; CARBONYLS, METAL; etc.), are dealt with in the organic chemistry articles.

Organic Chemistry, a main sub-section of CHEMISTRY, includes a historical introduction followed by a general survey of the subject. CHEMISTRY also includes an account of *Ultimate Organic Analysis*. There are, besides, articles explaining the structure and synthesis of carbon compounds, *e.g.*, ISOMERISM and STEREOCHEMISTRY; and processes and reagents are described under HYDROGENATION; GRIGNARD REAGENTS; etc. The various types and classes of compounds are dealt with in AZO COMPOUNDS; ALKALOIDS; ALCOHOLS; ESTERS; KETONES; CAMPHOR; PURINES; etc. Separate articles are devoted to the more important subgroups and members of these classes, *e.g.*, BUTYL ALCOHOLS; ALCOHOL (ethyl alcohol); BENZENE; CHLOROFORM; PYRIDINE; etc.; many being of industrial and medical importance. The chief substances present in living matter are treated under CARBOHYDRATES; CHLOROPHYLL, CHEMISTRY OF; PROTEINS; RESINS: *Natural and Synthetic;* etc.; and several organic acids have separate headings; *e.g.*, ACETIC ACID; OXALIC ACID; PHENOL OR CARBOLIC ACID; URIC ACID. Dyes and pigments are dealt with in DYES, NATURAL; and DYES, SYNTHETIC; and under various headings such as ALIZARIN; GLUCOSIDES, NATURAL; INDIGO; OCHRES; etc.

The physical chemistry articles include ADSORPTION; ASSOCIATION; CATALYSIS; HYDROGEN IONS; PHOTOCHEMISTRY; VALENCE; THERMODYNAMICS; etc. The industrial processes are treated in CHEMICAL ENGINEERING; COAL TAR; DISTILLATION; EXPLOSIVES; SUGAR; etc.; and under the separate headings of the various important elements and compounds. There is a large collection of diagrams of apparatus used in a chemical laboratory under CHEMICAL APPARATUS, and the methods of chemical analysis are described in CHEMISTRY: *Analytical,* which includes *Inorganic* (qualitative and quantitative), *Ultimate Organic* and *Gas Analysis;* and in FLAME and INDICATOR. There are also short articles interpreting old-fashioned names and dealing with various theories of the alchemists; *e.g.*, ALCHEMY; AQUA REGIA; ELIXIR; HARTSHORN, SPIRITS OF; and VITRIOL.

CHEMICAL ENGINEERING. In 1880 in London a group interested in chemical engineering as a new branch of engineering endeavoured to found "a Society of Chemical Engineers" but were too limited in number for the society to become a reality. However, George E. Davis gave a series of lectures in the Manchester Technical school in England in 1887, later embodied into a handbook which was of great value in those early years and was certainly the forerunner of modern chemical engineering, though the treatment was mostly qualitative. In this work Davis placed much emphasis upon what later were called unit operations and their importance in the chemical industry; he also stressed that the chemical engineer must have a wide knowledge of chemistry, physics, mechanics and materials of construction. Davis pointed out that the problem of corrosion is one of the distinctions between chemical engineering and other engineering fields and stressed how destructively this acts upon the materials used for building chemical plants.

In the United States the first curriculum in chemical engineering was established at the Massachusetts Institute of Technology, Cambridge, Mass., in 1888. William H. Walker joined this institute in 1903 and with his colleague, Warren K. Lewis, developed the unit operations technique for classifying and presenting chemical plant operational data. These two men first taught the subject as a formal course in about 1911; the term "unit operations" for these unitary physical changes was suggested by Arthur D Little about 1914. This concept of unit operations was extended by research and teaching by W. H. Walker, W. K. Lewis and W. H. McAdams and embodied in their book entitled *Principles of Chemical Engineering* first published in 1923 and revised several times thereafter. It made chemical engineering an exact and quantitative division of engineering by its formulation of laws and its interpretation of data.

In 1950 an excellent book appeared by G. G. Brown *et al.*, called simply *Unit Operations* which showed how this phase of chemical engineering had developed in the 50 years after Davis. In considering the development of chemical engineering the *Chemical Engineers Handbook* edited by John H. Perry also had a wide influence as it presents the quantitative formulas, their derivations and the tabulation of data required by modern chemical engineers.

The chemical aspects of chemical engineering were never completely lost sight of in the development and education of the chemical engineer. Gradually the interests of the chemist gravitated more to the laboratory functions and teaching. Starting about 1930 in the United States much more emphasis was placed upon the chemical changes for chemical engineers. As the unit operations concept for the physical changes had been so successful, the term unit processes was suggested by P. H. Groggins in 1928 for the corresponding chemical changes.

Chemical engineering owes much to the presentation of the unitary aspect for both its physical and chemical changes; this led to the elucidation of general principles both from research in the laboratory and from observation in the plants. Thus, quantitative principles were evolved pertaining to the entire chemical industry.

Function or Work.—The chemical engineer has as his field the industries where the making of chemicals or chemical change is commercialized. These are called chemical process industries.

Here the chemical engineer is largely removed from the laboratory to the plant, leaving to the chemist the laboratory for control, research and teaching. The chemical engineer frequently carries on research for new chemical processes or for improving processes, though the initial laboratory investigation is usually reserved for the chemists. However, the chemical engineer takes a process from the laboratory through the pilot plant where he checks the equipment needed by actual trial; he then completes the design and installs the large-scale equipment in a manufacturing establishment. He runs the factory and the industrial chemical processes; the latter is probably the area that employs the greatest number of chemical engineers.

An increasing number of chemical engineers at mid-20th century were using their chemical engineering training as a foundation for sales, sales service and management. The over-all function of the chemical engineer is to run the chemical process industry in all its phases.

Physical Changes or Unit Operations.—Occasionally in the manufacture of a chemical the processes involve only unit physical operations with no chemical change taking place, as, for instance, in the rectification of impure alcohol, the distillation of petroleum into its various constituents or the crystallization of a pure salt from a mixture. As a rule, however, the unit operations such as mixing, heat transmission or flow of fluids are tied up intimately with the chemical change. The names of the principal unit operations following Perry's arrangement are:

Flow of fluids	8. Drying
Heat transmission	9. Adsorption
Evaporation	10. Mechanical separations
Distillation and sublimation	11. Size reduction and size enlargement
Gas absorption	12. Mixing of material
Solvent extraction and dialysis	13. High-pressure technique
Humidification and cooling	14. Movement and storage of materials

Brown's classification of the unit operations is newer and more scientific. In it the individual physical changes are arranged under solids, fluids, separation by mass transfer, and energy and mass transfer rates. Both Perry's *Handbook* and Brown's *Unit Operations* should be consulted for the quantitative data for chemical engineering unit operations.

Chemical Changes or Unit Processes.—Unit processes can be defined as the carrying on of a chemical change in an economical way in a manufacturing establishment. It is much more difficult to develop the unitary aspect of a chemical change because of the much greater complexity and the larger number of variables involved. However, the distinction between chemical reactions in the laboratory and the unit process in the factory is important because it involves large-scale equipment and economics as well as unit operations. The principal unit processes are listed as follows:

1. Combustion	15. Sulphonation
2. Oxidation	16. Hydrolysis
3. Neutralization	17. Hydrogenation
4. Silicate formation	18. Alkylation
5. Causticization	19. Friedel-Crafts
6. Electrolysis	20. Condensation
7. Double decomposition	21. Polymerization
8. Calcination	22. Diazotization and coupling
9. Dehydration	23. Fermentation
10. Nitration	24. Pyrolysis or cracking
11. Esterification	25. Aromatization
12. Reduction	26. Isomerization
13. Ammonolysis	27. Acylation
14. Halogenation	28. Oxo reaction

These unit chemical changes all have certain aspects in common, such as kinetics, equilibrium, reactants, equipment, material balances and energy balances. In presenting the chemical changes, the basic fundaments should be arranged under these divisions for all reactions or for all unit processes. In research, advanced study and in the details of industrial application there are enough differences to require a more detailed classification under the respective unit processes. There is no need to divide any unit process into the traditional inorganic and organic changes. For example, nearly the same conditions and equipment with a variation in reactants and catalysis have enabled an ammonia plant (inorganic) to be converted into a methanol (organic) establishment. The yields and conversions and other cost factors must always be considered. As research progressed a more quantitative foundation was placed under the respective unit processes.

Kinetics and Catalysis.—Because he is of necessity interested in the cost of his products, the chemical engineer is always concerned with the kinetics of the reaction; that is, the time required for a chemical reaction to proceed to a given extent. If this time needs to be reduced he turns to the use of catalysts to speed the course of the reaction. Indeed some of the most important work done by the chemical engineer in making chemicals at low cost for the consuming industries and the public has been in just such applications of basic physical chemistry to industrial chemical changes. In 1914 more suitable catalysts were discovered which increased the rate of the formation of ammonia. These reduced the cost of manufacturing ammonia and made it the basis of the present satisfactory condition of the world supply of nitrogen compounds. Ammonia could then be employed for the manufacture of many other nitrogen compounds, for fertilizers, explosives, resins, dyes and countless other applications. The kinetics of the reaction have a direct influence upon the expenditure for the equipment. If a given reaction can be made to proceed in one-half the time previously needed, it will require smaller equipment, and hence a decreased investment of capital for a plant to manufacture a required tonnage.

Equilibrium.—Likewise the chemical engineer is economically interested in how far a reaction will go, or its equilibrium. He will take advantage of the basic laws of physical chemistry, for instance that of mass action, to allow him to attain more favourable equilibrium conditions for a given reaction. This will influence the cost of the materials that enter into the making of a chemical such as ammonia or sulphur trioxide. If it is of sufficient interest, extensive equilibrium studies will be undertaken to determine the exact conditions of temperature, pressure and proportion of reactants that will furnish the most favourable result. Indeed these results will often be plotted as curves against the important variables. As was done in the case of ammonia, the chemical engineer will increase the pressure, following the principle of Le Chatelier, if there is a diminution in the relative number of molecules in the product. The higher pressure will cause a higher percentage of conversion of reactants to ammonia. On the other hand, this entails more expensive equipment to withstand these higher pressures. One of the functions of the chemical engineer is to balance the advantage of getting the more favourable equilibrium conditions against the expense entailed for both equipment and operation under this higher pressure.

Yields and Conversions.—The operational efficiency of chemical plants is interpreted in terms of the yield and conversion. These terms may be defined as follows:

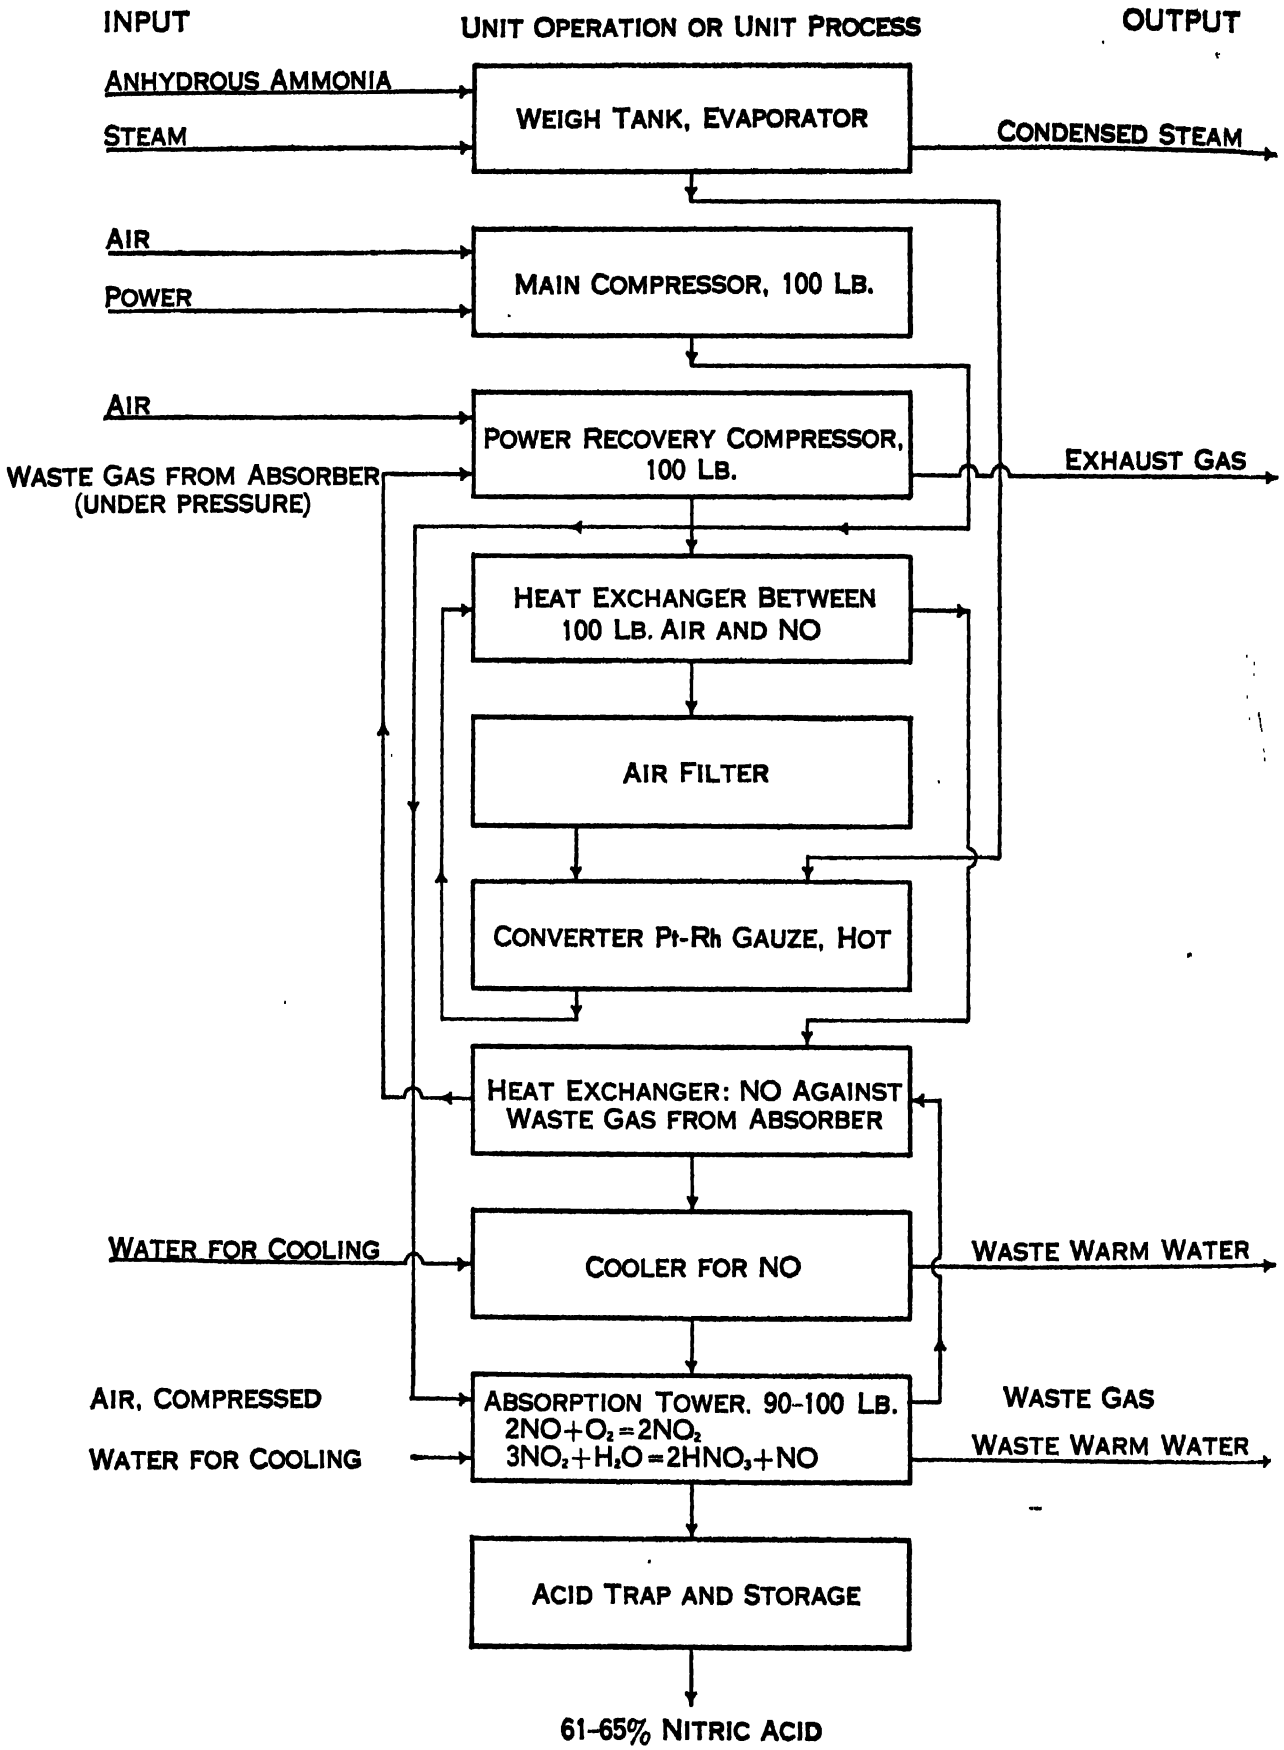
$$\text{Percentage yield} = 100 \times \frac{\text{moles of main product}}{\text{moles of main product equivalent to net disappearance of chief reactant}}$$

$$\text{Percentage conversion} = 100 \times \frac{\text{moles of main product}}{\text{moles of main product equivalent to chief reactant charged}}$$

Considering the synthesis of ammonia at 300 atmospheres and 500° C. the yield is frequently about 98% while the conversion will be limited by the equilibrium figure of about 20%. This means that 80% of the charge does not react and must be recirculated. Somewhat similar figures prevail for the methanol synthesis.

The aim of the chemical engineer, concerned with the cost, is to have the conversion figures approach or equal the yield as closely as possible. This is, of course, not feasible with the ammonia reaction because of the low equilibrium results. As a corollary of the low ammonia and methanol conversions, larger equipment is required than would be necessary were the conversion figures nearer to those of the yield.

Flow Sheets.—The demand for a graphic and accurate presentation of a process led to flow sheets or flow diagrams. In these the raw materials are subjected to a co-ordinated sequence of unit chemical changes or unit physical changes to make the resulting product with or without by-products. These depict the flow and expenditure of material, energy, time and labour. The energy should include that for power, heat and chemical change. These flow sheets may be simply block type (fig. 1) or diagrammatic (fig. 2). In the latter the separate parts of the diagram



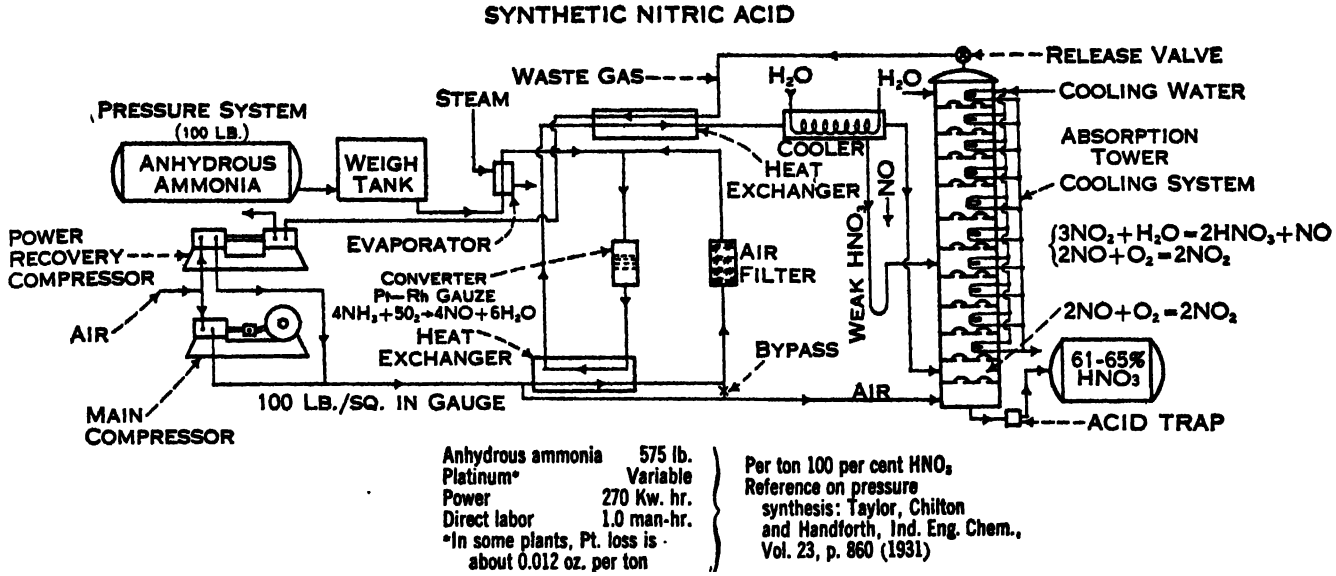


FIG. 1.—BLOCK STYLE OF FLOW SHEET FOR SYNTHETIC NITRIC ACID (100 LB. PRESSURE) FROM AMMONIA

FROM R. NORRIS SHREVE, "CHEMICAL PROCESS INDUSTRIES," COURTESY MCGRAW-HILL BOOK COMPANY

FIG. 2.—DIAGRAMMATIC FLOW SHEET FOR SYNTHETIC (100 LB. PRESSURE) FROM AMMONIA

simulate the apparatus needed for the respective units. More complex or more complete flow sheets are elaborated as the work proceeds from the initial concept of the process until the final flow sheets become the basis for construction with each valve and pipe as well as all equipment drawn in with the proper size and position. Such flow sheets represent on paper the chemical engineer's concept of a given process as a summation of unit processes or chemical changes and unit operations or physical changes necessary to convert the materials into the finished products.

Material Balances.—In the economical design of any process, the amount of raw materials entered should be balanced against the materials leaving the process, with any chemical transformations calculated and taken into consideration. Such a balance shows at once any losses and may lead to reduced cost or point the way for proper investigation to reduce or remove such losses.

Energy Balances.—Similarly, such comparisons are made for energy by equating all energy entering a process against that leaving, taking into consideration any energy transformation in or out of the process. Much of the cost-reducing action of the chemical engineer is connected with his use of these two balances of material and energy. Indeed many flow sheets have as an essential part of their presentation the determination of these two balances (*see* fig. 2).

Pilot Plants.—After the chemist has worked out a process in the laboratory on the test-tube scale, it should be turned over to the chemical engineer for his quantitative design and for his operation on a pilot-plant scale. The pilot plant should be a small replica of what the designing engineer judges the large plant will be like. Here all phases of the unit chemical processes become intimately connected with unit physical operations. Although the chemical changes have been studied in the laboratory, and the best calculations and most suitable designs made, it is only in the pilot plant that they can be checked. The experienced chemical engineer, knowing with what materials he will deal in his process, designs the pilot plant to have minimum corrosion. He must test these conditions, however, in the pilot plant as well as investigate the application of the unit operations of heat transfer, mixing, distillation, filtration, etc. on this small-scale replica equipment. The chemical engineer determines in the pilot plant whether his design is efficient and if not, makes the correction on a small scale. One of the characteristics of the chemical process industry as run by the chemical engineer is the extensive use of pilot plants for precisely this determination. Indeed, in the development of a new process or improvement of an old process, the pilot plant is frequently the most important factor in ensuring success in the undertaking.

Materials of Construction.—Since corrosion of materials of construction is caused by chemicals, its avoidance is one of the most important principles in the design, operation or improvement of most any process in the chemical field. The proper choice of materials of construction offers the experienced chemical engineer an opportunity to design and supervise a chemical plant in a manner that will save costly breakdowns and repairs. Here great progress was made in discovering and applying many new materials of construction in the chemical plant. Among such can be named carbon of various types, synthetic rubber, new resins, new plastics and new alloys such as improved stainless steels. Likewise reductions in the price of long known but still costly metals, such as tantalum, were helpful. Because of this corrosion, the chemical engineer frequently designs equipment not according to a minimum for mechanical strength but with safety factor sufficiently large to allow for unavoidable corrosion.

Design and Equipment.—In the field of chemical engineering design, the type of equipment employed is of utmost importance as it is in all engineering. While almost all chemical engineers are concerned with design and equipment in certain phases of their work, a few work exclusively with the design and building of equipment. On the other hand, much of the progress in the chemical process industries is dependent upon improvements in the design of equipment. For large-scale operations the change from batch to continuous processes is an important step in the reduction of costs and in the maintenance of uniformity of quality. The use of pipes or towers in carrying on continuously the various steps required for manufacture in the petroleum industry has been one of the most important aspects of the large-scale and low-cost manufacturing as practised in this industry. The use of such equipment became more widespread in other phases of chemical processes as exemplified by the manufacture of a number of chemicals in continuous pipe autoclaves such as are used in one of the steps in making phenol from chlorobenzene.

Chemical Process Industries.—This classification, frequently used by the chemical engineer, was evolved out of the older applied or industrial chemistry. Under this designation an industry is classified by the chief product or classes of products from the industry such as rubber, alkali, plastics, petroleum, ceramics, cement, glass, electrolytic industry, nitrogen industry, paint, leather, vegetable oils, fats, pulp and paper, soaps, synthetic fibres, intermediates and dyes, organic chemicals and many others. It is the chief function of the chemical engineer to run these industries, design, improve and operate them. He naturally takes the basic principles involved in the physical changes or unit operations and chemical changes or unit processes and applies these to a specific industry in order to give better service to the consuming public by improving the quality and reducing the cost of his product.

Wastes.—The discharge of industrial wastes into the air,

streams or on the land is objectionable, and often subject to stringent legislation. The reduction or elimination of such wastes is often a highly specialized problem requiring a chemical engineer experienced in the particular industry to handle this adequately and economically.

Safety and Fire Protection.—In the operation of any of the chemical process industries the safety and protection of the plant and workers is a part of the responsibility of the chemical engineer. In many cases insurance companies hire chemical engineers to aid them in the introduction of safety and protection procedures in the plants they insure.

Process Control and Instrumentation.—The chemical industry is one of the leaders in the use of instruments to reduce labour in the operation of its processes and to insure the maintenance of the conditions required to produce products of high quality and low cost. The use of instruments was greatly expanded when the chemical engineer turned from batch processing to continuous processing. New instruments were developed by manufacturers which even show initial trends in any changes, physical or chemical, and take means to correct these trends if in the wrong direction. The emphasis in instrumentation is more upon actual process control than upon simply the recording of temperature, pressure or other variables important though these latter still are.

Accounting and Cost Finding.—As an engineer is concerned with the making of useful products at a low cost in order to insure wide consumption, the economics of this process are constantly his responsibility. Any number of chemical companies take chemical engineers and train them specifically in accounting methods for the most efficient control of costs. As the chemical engineer, unlike the chemist, is always involved in the competitive production of his product, broad principles of economics as well as the details of his costs are an important part of his responsibility.

Plant Location.—Before the installation of any process, the proper location of the plant must be determined. This involves not only the sources of raw material, fuel and power but also labour supply, markets, transportation facilities and any local restrictive laws. Particularly in the chemical process industries, water resources are a decisive factor in the selection of a plant site. Frequently a chemical plant engaged in the manufacture of paper, plastics, dyes, intermediates or the like, will use many times the amount of water employed by the city or small town in which the plant is located. To save costs in the utilization of water, chemical plants find it necessary to have multiple supplies of varying purity according to the need. This may range from the use of surface water for sanitation to deep well water for cooling or distilled or deionized water for the making of pure chemicals.

State Registration.—In order to maintain standards and protect the public from untrained engineers, many states enacted laws with requirements for registration. Such registration is based on education, experience and examinations and is required when the public is involved in the work of the engineer. The requirement that engineers be registered is becoming more widespread.

Professional Societies.—In order to help continue the professional and technical growth of the chemical engineers and to facilitate exchange of information particularly in newer fields, professional societies are essential. They continue much of the educational work begun in the universities.

Among such professional societies is the American Institute of Chemical Engineers, founded in 1908. The institute has various classes of membership graded according to the experience and training of the chemical engineer. It publishes *Chemical Engineering Progress*. The Institution of Chemical Engineers of London, a comparable organization, publishes its *Transactions*.

The American Chemical society embraces both chemists and chemical engineers and includes not only the theoretical fundamentals but also the application of chemistry.

Responsibility.—The main responsibility of the chemical engineer is to run the chemical process industries. This responsibility is also directly connected with a larger contribution to society in supplying the products of the chemical industry at reasonable costs and with an ever-increasing field of application. The reasonable cost is realized through the competition between chemical engineers in different companies or different plants of the same company.

CHEMICAL EQUILIBRIUM. A chemical reaction may, under appropriate conditions of temperature, pressure and concentration, proceed not to completion but to a state of balance between all the reactants and products. The incompleteness of the reaction is caused by the fact that the reaction is reversible; *i.e.*, by the fact that the products of the reaction in one direction, as soon as they begin to form, begin to react to produce the original reactants. A balance, called equilibrium, is attained when the two opposing reactions go on at equal rates; there is then no net change in the amounts of the substances involved. A change in temperature, pressure or concentration may temporarily upset the equality of the two rates so that one reaction gains over the other until equilibrium is again established.

It is not easy for a reader unfamiliar with chemistry to visualize simultaneous, opposing chemical reactions; so it is well to begin with a more "physical" equilibrium, that between a liquid and its vapour. The change from one to the other is quite reversible; liquids evaporate and vapours can be condensed to liquids. But if some liquid is introduced into a large, evacuated vessel, held at constant temperature, molecules rapidly pass from the liquid into vapour, until they reach a certain concentration, or pressure, at which the number evaporating per second per square centimetre of surface is just balanced by the number of vapour molecules being recaptured by the liquid per second per square centimetre. If some of the vapour is pumped out, the two rates are thrown temporarily out of balance; evaporation proceeds at the previous rate while condensation is reduced, but this difference of rates builds up the concentration of vapour till the balance is again restored. A rise in temperature brings about a new equilibrium, because the molecules are all made to move faster, making it easier for them to escape from their mutual attraction in the liquid and requiring a higher concentration of them in the vapour to restore equilibrium. The essential test for a state of equilibrium is the ability of the system to readjust so as to neutralize, so far as possible, the effect of the change. This general principle is known as the theorem of Le Chatelier. It applies not only to a physical equilibrium, such as that between liquid and vapour, but equally to a chemical equilibrium, such as that between calcium carbonate, $CaCO_3$, and its decomposition products, solid calcium oxide, CaO, and carbon dioxide gas, CO_2, the chemical equation for which is, $CaCO_3 = CaO + CO_2$. The reversibility of the reaction is proven on the one hand by the decomposition of limestone by heating in a lime kiln and, on the other, by the ability of CaO to absorb CO_2 at ordinary temperatures. The reversibility of a reaction is often indicated by writing double arrows with the equality sign, thus $\rightleftharpoons$, often abbreviated to $\rightleftharpoons$. These representations should not obscure the significance of the equality sign, which is the conservation of atoms and masses. The two reactions are complete under the respective conditions just stated, but this reversibility indicates that there are intermediate conditions under which equilibrium is possible. The relation between temperature, t, in degrees Centigrade, and equilibrium pressure, P, in atmospheres, for this particular equilibrium is as follows:

t	842	855	869	904	937;
P	0.45	0.53	0.67	1.16	1.77

An equilibrium involving two or more visually detectable and mechanically separable phases, solid, liquid or gas, is called a heterogeneous equilibrium; one existing within a single phase, either liquid or gas, is a homogeneous equilibrium. As an example of the latter we may consider the partial ionization of acetic acid into charged ions, according to the equation, $HC_2H_3O_2 \rightleftharpoons H^+ + C_2H_3O_2^-$. If one gram-molecule, or mole, of the acid is dissolved in one litre of water, at 25° C., equilibrium is reached almost instantly with 0.0042 moles each of H^+ and $C_2H_3O_2^-$ and 0.9958 moles of un-ionized acid. If a little sodium acetate is added, which ionizes almost completely into Na^+ and $C_2H_3O_2^-$, the rate of reaction to the left is increased but the reaction to the right proceeds as before; consequently, the concentration of the H^+ is quickly reduced to such a value that the rates are again equal. Similarly, the addition of H^+ from another source, such as hydrochloric acid, would reduce the concentration of $C_2H_3O_2^-$ to a new equilibrium value. Dilution of the solution with water would diminish the rate of collision and recombination of the two ions until enough additional ions are formed to enable their rate of recombination again to equal their rate of formation. The fraction of the acid existing as ions is therefore increased by dilution.

These relations may be given an approximate quantitative formulation. The number of moles of acetic acid per litre decomposing per second into ions depends, at any one temperature, only on its concentration, which is customarily expressed by the formula in parentheses. The velocity of the reaction to the right, v_1, is $v_1 = k_1 (HC_2H_3O_2)$ where k_1 is the constant of proportionality. The velocity of the reaction to the left, v_2, is similarly given by $v_2 = k_2 (H^+)(C_2H_3O_2^-)$. At equilibrium, $v_1 = v_2$; therefore $(H^+)(C_2H_3O_2^-)/(HC_2H_3O_2) = k_1/k_2 = K$, the equilibrium constant. Its value for acetic acid can be obtained from the set of equilibrium concentrations previously given, as 1.8×10^{-5}. This constant expresses the strength of the acid and is valid for any set of concentrations at 25° C. In a solution of 0.1 mole of acetic acid per litre, for example, $(H^+) = (C_2H_3O_2^-)$ and $(HC_2H_3O_2)$ is still approximately 0.1; therefore, $(H^+)^2 = 1.8 \times 10^{-6}$ and $(H^+) = 1.3 \times 10^{-3}$. Again, in a mixture of an equal number of moles of $HC_2H_3O_2$ and $NaC_2H_3O_2$, $(HC_2H_3O_2) = (C_2H_3O_2^-)$ and hence $(H^+) = 1.8 \times 10^{-5}$. We thus have the means, by altering the relative amounts of acetic acid and acetate ion, of establishing any desired acidity through a wide range.

The following examples illustrate equations for equilibrium constants corresponding to equations for chemical reactions.

$$2SO_3 = 2SO_2 + O_2 \text{ (all gases)}: \frac{(SO_2)^2(O_2)}{(SO_3)^2} = K$$

Since the concentration of a gas is proportional to its partial pressure in a gas mixture, this equilibrium may also be expressed in terms of partial pressures, $P^2_{SO_2} P_{O_2} / P^2_{SO_3} = K_p$.

$$CO_2 + C \text{ (solid)} = 2CO; \ (CO)^2/(CO_2) = K \text{ or } P^2_{CO}/P_{CO_2} = K_p$$

Note that the concentration of solid carbon is not susceptible to change and therefore need not be expressed in the equilibrium equation.

$$3Fe \text{ (solid)} + 4H_2O \text{ (gas)} = Fe_3O_4 \text{ (solid)} + 4H_2 \text{ (gas)}$$
$$P_{H_2}{}^4/P_{(H_2O)^4} = K; \text{ or } P_{H_2}/P_{H_2O} = K'$$

$$Ca(OH)_2 \text{ (solid)} = Ca^{++} + 2OH^-; \ (Ca^{++})(OH^-)^2 = K$$

The effect of total pressure upon an equilibrium involving gases is to favour the state with a smaller number of gas molecules. Thus, in the following equilibria, $H_2 + I_2 = 2HI$, $2SO_2 + O_2 = 2SO_3$, $N_2 + 3H_2 = 2NH_3$, $CO_2 + C$ (solid) $= 2CO$, increasing the total pressure would have no effect upon the first; it would shift the second to the right, the third still more to the right and the fourth to the left. Each effect can be calculated quantitatively from the expression for the equilibrium constant and the condition that the total pressure is the sum of the partial pressures.

The effect of temperature upon an equilibrium depends upon the heat absorbed or evolved when the reaction occurs under equilibrium conditions. If a vessel containing an equilibrium mixture is transferred from a lower to a higher temperature, heat will, of course, flow into the mixture, and it will shift the equilibrium in that direction which absorbs heat. In the reactions,

$$H^+ + OH^- = H_2O + 13.7 \text{ kg.cal.},$$
$$N_2 + 3H_2 = 2NH_3 + 24.0 \text{ kg.cal.},$$
$$H_2 + I_2 \text{ (gas)} = 2HI - 2.8 \text{ kg.cal.},$$

the equilibria are shifted by rising temperature in favour of the substances on the left-hand side, in the first two cases, and in favour of more HI, in the third.

The effect of changing temperature is given quantitatively by the approximate equation,

$$\log_{10} \frac{K_1}{K_2} = \frac{\Delta H}{4.575} \frac{(T_2 - T_1)}{(T_1 T_2)}$$

where ΔH is the heat, in calories, absorbed by the reaction as written, and K_2 and K_1 are the equilibrium constants at the respective temperatures, T_2 and T_1, on the Kelvin scale.

The Haber process for the chemical utilization of the inert nitrogen of the air furnishes a striking instance of the practical fruits of the principles of equilibrium. The reaction, $N_2 + 3H_2 = 2NH_3$, does not take place at all when nitrogen and hydrogen are brought together under any ordinary conditions, whereas ammonia is easily decomposed on moderate heating. The principles of equilibrium teach that the equilibrium would be displaced in favour of ammonia by increasing pressure and lowering temperature. But lowering temperature normally decreases the velocity at which equilibrium is approached; so a compromise is necessary here, and a catalyst to increase speed is indicated. Proceeding in this way, Fritz Haber was able to obtain a small equilibrium concentration of ammonia, from which he calculated the equilibrium constant and the effect of temperature thereon. With this knowledge the desirable conditions could be predicted for obtaining an industrially profitable equilibrium concentration of ammonia.

Catalysts have been developed which cause the reaction to proceed at reasonable speed at 500° C. assisted by pressures of the order of 100 atmospheres, pressures unprecedented in technical processes at the time of Haber's investigation. These high pressures also shift the equilibrium strongly in favour of ammonia since four molecules become two in the reaction. Even so, the conversion to ammonia in one contact with the catalyst is only about 10%, but by liquefying and removing this ammonia, and repassing the nitrogen and hydrogen, augmented, over the catalyst, the equilibrium amount is again obtained, and so on. The ammonia thus obtained is used in part for refrigeration, in part oxidized to nitric acid for the multitude of uses of that important chemical and in large part converted into ammonium sulphate for fertilizer. It is safe to say that no amount of unscientific empiricism would ever have produced these results.

(*See* THERMODYNAMICS.) (J. H. HD.)

CHEMICAL SOCIETIES. Chemical organizations are among the most active agencies for promoting the increase and diffusion of chemical knowledge. At first, the chemists functioned purely within such general scientific bodies as the Royal Society of London. In the closing decades of the 18th century, however, a few chemical societies sprang up in England, Scotland and the United States. Some doubt exists as to the order of priority in which these societies were formed, but the most likely sequence seems to be: a London chemical society (1782); a chemical society at the University of Edinburgh (1785) composed of the students of Joseph Black; a chemical society at the University of Glasgow (1786), a chemical society in Manchester (prior to 1787); the Chemical Society of Philadelphia (founded by James Woodhouse in 1792); another chemical society in Glasgow (1798); and a chemical society of Edinburgh in 1800. The present Chemical Society of London dates from 1841.

There follows a list of some of the leading chemical societies in the principal countries of the world, together with some of their publications:

ARGENTINA. Buenos Aires, Asociación Química Argentina (founded 1912)—*Anales* (1913 *et seq.*). AUSTRALIA. Melbourne, Australian Chemical Institute (1917)—*The Australian Chemical*

Institute Journal and Proceedings (1934 *et seq.*); Melbourne, Society of Chemical Industry of Victoria (1900)—*Bulletin* (1887 *et seq.*). AUSTRIA. Vienna, Chemische-physikalische Gesellschaft (1869)—*Physik and Chimie* (1895–1938); Vienna, Verein Österreichischer Chemiker (1898)—*Österreichische Chemiker-zeitung.* BELGIUM. Brussels, Société Chimique de Belgique (1887)—*Bulletin;* Federation des Industries Chimiques de Belgique. CANADA. Toronto, Canadian Institute of Chemistry (1916)—*Canadian Chemistry and Process Industries* (1917 *et seq.*); Canadian Institute of Chemistry (1916)—*Canadian Chemistry and Metallurgy* (1916 *et seq.*). CZECHOSLOVAK REPUBLIC. Společnost pro Průmysl Chemiský v—*Kralovstrí Cheshem* (Prague). FRANCE. Association des Chimistes de Sucrerie et Distillerie de France et des Colonies (1882)—*Bulletin* (1883 *et seq.*); Paris, Cercle de Chimie (1917)—*Revue des Produits Chimiques;* Paris, Société Chimique de France (1857)—*Bulletin de la Société Chimique de France* (1858–1933), *Documentation* (1933 *et seq.*), *Memoires* (1934 *et seq.*); Société de Chimie Biologique—*Bulletin de la Société de Chimie Biologique* (1919 *et seq.*); Société de Chimie Industrielle (1917)—*Chimie et Industrie annales de Chimie Analytique* (1918); Union Internationale de Chimie (League of Nations, 1919)—*Comptes Rendus, Rapports.* GERMANY. Adolf-Baeyer-Gesellschaft zur Förderung der Chemischen Literatur; Halle, Deutsche Bunsen-gesellschaft für Angewandte Physikalische Chemie (1894); Berlin, Deutsche Chemische Gesellschaft (1867)—*Berichte, Chemisches Zentralblatt, Bibleographica Chemica* (1922 *et seq.*); Leipzig, Kolloid-Gesellschaft (1922?)—*Kolloid-Zeitschrift;* Berlin, Verein Deutscher Chemiker (1887)—*Angewante Chemie* (1887 *et seq.*), *Die Chemische Fabrik* (1928 *et seq.*); Berlin, Verein Deutscher Lebensmittelchemiker (1902)—*Vorratspflege and Lebensmittelforschung, Zeitschrift für Untersuchung der Lebensmittel;* Verein zur Wahrung der Interessen der Ehemireben Industrie Deutschlands—*Die Chemische Industrie* (1877 *et seq.*). GREAT BRITAIN. London, Biochemical Society (1911)—*Biochemical Journal;* Chemical Society (1841, incorporated 1848)—*Annual Reports* (1904 *et seq.*), *British Chemical and Physiological Abstracts* (1926 *et seq.*), *Journal of the Chemical Society* (1847 *et seq.*), *Memoirs and Proceedings* (1841–48), *Proceedings* (1885 *et seq.*); London, Faraday Society (1903)—*Proceedings* (1904–15), *Transactions* (1905); Oil and Colour Chemists' Association—*Journal;* London, Society of Chemical Industry (1881, inc. 1907)—*Journal* (1882 *et seq.*), *Report of the Progress of Applied Chemistry* (1916 *et seq.*); Society of Dyers and Colourists—*Journal;* Society of Leather Trades' Chemists—*Journal;* London, Society of Public Analysts (1874)—*The Analyst* (1887 *et seq.*). INDIA. Calcutta, Indian Chemical Society (1924)—*Monthly Journal, Quarterly Journal Industrial and News Edition, Report.* ITALY. Rome, Associazione Italiana di Chimica (1919)—*Annali di Chimica Applicata, Chimica e l'industria, Gazetta Chimica Italiana;* Associazone Italiana di Chemica Generale ed Applicata, *Gazzetta Chimica Italiana* (1871 *et seq.*); Milan, Associazione Italiana di Chimica Tessili e Coloristica (1925)—*Bollettina;* Societa di Chimica Industriale di Milana (1895)—*Annuario* (1896 *et seq.*), *Giornale di Chimica Industriale ed Applicato* (1919 *et seq.*). JAPAN. Tokyo, Nippon Kagaku Kai (1878)—*Journal (Nippon Kagaku Kai Shi)* (1880), *Bulletin* (1926); Kogyo Kagaku Kai (1898)—*Kogyo Kagaku.* LATVIA. Riga, Latvijas Kimijas Biedriba (1920). MAURITIUS. Port Louis, Société des Chimistes de Maurice (1910)—*Revue Agricole de l'Ile Maurice.* NETHERLANDS. Nederlandsche Chemische Vereeniging (1902)—*Chemisch Weekblad* (1903 *et seq.*), *Recueil des Travaux Chemiques des Pays-Bas;* Vereeniging van de Nederlandsche—*Chemische Industrie.* NORWAY. Oslo, Norsk Kjemisk Selskap (1893)—*Tidsskrift for Kjemi og Bergvesen.* POLAND. Warsaw, Polskie Towarzystwo Chemiczne (1919)—*Roczniki Chemji.* PORTUGAL. *Sociedade Chimica Portuguesa* (1912)—*Revista de Chimica Pura e Applicada* (1916 *et seq.*); Coimbra, Sociedade Portuguesa de Quimica e Fisica—*Revista de Chimica Pura e Applicada* (1905 *et seq.*). CHEMICAL WARFARE. Chemical warfare relates to the employment of substances useful in war by reason of their direct chemical action. Chemistry has found application in military science throughout recorded history. It was not, however, until the 20th century that chemical warfare in the modern acceptance of that term became a distinct feature of military technique. Modern chemical warfare represents essentially the application of chemical energy in military action, in contrast to physical energy as represented by the impact of bullets or the shock of explosives. The substances employed in chemical warfare are known as "chemical agents." Those that react directly on the human organism are war gases. A second group of agents which are useful in obscuring distant objects are called smokes. A third group are incendiaries or fire-producers.

In each case the desired end is served by chemical reactions that take place after the appropriate agent has been released to atmospheric conditions of pressure and temperature. It is to be noted that these reactions are not necessarily instantaneous, as is the case where firearms or explosives are employed; chemical warfare agents on the contrary may act slowly and continue effective for extended periods of time.

Modern chemical warfare must be regarded as a product of industrial chemistry. Although the chemicals it employs have been known for many years, some of them for many centuries, yet only in relatively recent years has production capacity been available to permit the manufacture of the large quantities of these substances that are required for extended military operations.

Development.—The application of chemical warfare really commenced before recorded history by the use of fire and smoke to overcome an opponent. At the siege of Plataea in 429 B.C. burning pitch and sulphur were used. The so-called "Greek fire" was a mixture of highly combustible substances ignited on water. In 1855 Lord Dundonald proposed the use of burning sulphur on a large scale under favourable wind conditions during the siege of Sebastopol. During the U.S. Civil War it was proposed (1862) that shell containing chlorine be employed by the Union forces.

The science of chemistry advanced rapidly during the 18th and 19th centuries, and the use of toxic substances was foreseen and considered at the Hague Conference of 1899. With the exception of the United States, the great powers there pledged themselves not to use projectiles whose sole object was the diffusion of asphyxiating or harmful gases.

World War I.—The adoption of chemicals as weapons during World War I was logical in that the principal combatant nations were highly developed scientifically and industrially. A stalemate had been reached when both sides entrenched themselves so firmly that advance was impracticable without terrific losses. Means were sought to restore open warfare. At the outbreak of the war, none of the combatant nations was prepared to use or defend against chemicals.

The introduction of gas as an effective weapon in modern warfare actually dates from April 22, 1915, when the Germans launched a large-scale cylinder attack with chlorine against the Allied position in the Ypres salient where the British and French lines joined. Although intelligence reports had given warnings of an impending attack, little credence was given to them by the Allies. The attack came as a complete surprise to unprotected troops; its success was so far beyond German expectations that adequate reserves to exploit the breakthrough for a decisive stroke had not been provided. Within a few days Allied troops were equipped with pads of cotton dipped in a chemical solution and tied over the nose and mouth. These were soon followed by a crude form of respirator which was continually improved throughout the war both for comfort and efficiency. As protection was obtained against one chemical, the offense sought for and introduced new agents. These frequently required radical changes in the mask. Cloud gas attacks, although highly efficient, were entirely dependent on favourable wind conditions. Consequently the extensive use of gas shell was begun in 1916. This also permitted employment of a greater number of toxic substances.

Lacrimators, sneeze gases and vesicants were introduced as the war progressed, the Germans leading the way. Because of the manufacturing problem, many months were generally required for Allied retaliation in kind. In July 1917, the Germans introduced mustard gas, an extremely vesicant, highly persistent liquid, which causes severe, slow-healing burns. It was difficult to provide effective protection against this agent, which accounted for the majority of gas casualties during World War I.

Use After 1918.—Because of its controversial aspects, European powers have shrouded with silence their recent operations in the field of chemical warfare. However, all of the major world powers have maintained research facilities. Some have manufacturing facilities and chemical troops. The speedy conquest of Ethiopia by Italy has been ascribed to the extensive use of a vesicant material similar to mustard gas; against the unprotected native, its vesicant qualities proved irresistible. In China and in Spain, chemical warfare appeared chiefly as incendiaries, much damage thus being caused.

The use of toxic chemicals during the European war in 1939–40 had not been confirmed up to July 1940. Incendiary bombs were extensively used in air raids by both sides. Probably the chief use of chemical warfare was in the extensive adaptation of screening smoke tactics to both land and sea battles. Germany utilized smoke tactics with exceptional efficiency to blind observation, eliminate enemy-aimed fire and to immobilize enemy movements attempted within smoke. These tactics were especially effective during the closing weeks of the campaign in France to facilitate river crossings, establish bridgeheads, and to assist the rapid advance of infantry and tanks. On the sea, the German pocket battleship "Admiral Graf Spee" dispersed smoke in an attempt to blind its movements from enemy fire. This might have been more successful if a British observation plane had not been able to give accurate information as to course of the ship. During the spring of 1940 the German battleship "Scharnhorst," after being crippled in action, was hidden within a smoke screen laid by a friendly cruiser and was thus enabled to escape.

Chemical Agents.—The term gas is applied to those chemical agents used in war which, by ordinary and direct chemical action, produce a toxic or powerful irritant effect on the human body. Solids, liquids or true gases may be so employed; however, in their actual use on the battle area, the solid or liquid is converted by normal or artificial volatilization into a true gas or disseminated as minute solid or liquid particles called aerosols. Irritant smokes are types of aerosols included under the term gas because their principal use is for their physiological effect.

From the military viewpoint the most important classifications of chemical agents are in accordance with (1) physiological effect, (2) persistency and (3) tactical use.

Physiological effect classifies the chemical according to its primary action on the human body even though it may produce other secondary effects. The severity of effect is roughly proportional to the concentration (amount present in a unit volume of air) and the time of exposure.

Lung irritants act on the respiratory system and are often lethal. When breathed, they irritate and inflame the interior portion of the bronchial tubes and lungs, cause coughing, impede breathing, and, in severe cases, acute pulmonary oedema will result. Chlorine, phosgene and diphosgene are examples.

Vesicants or skin-blistering agents attack any part of the body with which the liquid or vapour comes in contact, especially moistened parts. They are absorbed or dissolved on exterior or interior parts of the body, followed by production of inflammation, burns and destruction of tissue. There is no immediate pain and effect is delayed for some period after exposure. Protection against this class is very difficult because of its insidious action by contact with the liquid or prolonged exposure to the vapour. Examples are mustard gas, lewisite and ethyldichlorarsine.

Sternutators or sneeze gases are also known as irritant smokes. They are disseminated into the air as minute solid or liquid particles which, if inhaled, cause sneezing, intense pain in the nose, throat and chest followed by violent nausea, headache, mental depression and physical weakness. No fatal cases have been recorded from this class; effect, although severe, is temporary, lasting about 12 hours. The charcoal and soda lime mixture of the gas mask canister will not remove these small particles from the air. A most efficient mechanical filter is necessary to give protection. Diphenylaminechlorarsine, an aromatic arsenical derivative, is an example.

Lacrimators or tear gases irritate the mucous membrane around the eyes, causing intense smarting and a profuse flow of tears with resultant hampering of vision. Effect from concentrations in the field is only temporary, recovery being complete within a few minutes after removal from the contaminated area. Chloracetophenone, brombenzylcyanide and xylyl bromide are examples.

The systemic poisons directly affect the heart action, nerve reflexes, or interfere with absorption and assimilation of oxygen by the body. Carbon monoxide and hydrocyanic acid, which pertain to this class, have never been effectively used in war because of their relative lightness compared with air with the consequent difficulty in placing satisfactory quantities on a given area.

The persistency of a chemical agent is determined by the length of time it will maintain an effective concentration without being renewed. Those chemicals which remain effective for longer than ten minutes after release in the open are defined as persistent. Usually dispersed in the liquid state, persistent agents contaminate the ground on which released and continue to give off dangerous vapour for long periods. Nonpersistent gases are those whose effectiveness in the open continues for less than ten minutes. They vaporize rapidly, forming concentrated clouds which drift with the wind, increasing in size but becoming diluted in gas content until they finally disappear.

Tactical classification, which is influenced by the persistency, is based on the primary military objective for which any particular chemical is used in the field. War gases are thus classified as casualty or harassing agents; smokes as screening agents; and the various fire producers as incendiaries.

No attempt will be made to enumerate all the chemical agents which might be used in war. Many thousands of compounds were thoroughly studied during World War I. Comparatively few were deemed worthy of test under battle conditions and of those only about a dozen were in actual use at the termination of that war. The majority of chemical warfare agents are organic compounds of which the theoretical number is almost limitless. From these, it is quite possible that more effective war chemicals will be found. On the other hand it is more probable that modification of types now known or more efficient methods of dispersion will first appear rather than entirely new discoveries.

To be useful as a chemical agent, certain requisites must be met. These include: adequate and utilizable physiological action, screening power, or incendiary effect; stability in storage and in contact with moisture; capability of manufacture on large scale at low cost from easily procurable, nonstrategic raw materials; suitability for safe handling, transporting and loading in munitions without corrosive effect on ordinary steel; capability of being disseminated in effective quantity under field conditions; gases, preferably much heavier than air, readily compressed to liquids and easily vaporized when released.

Brief descriptions of a few type chemical agents follow:

Phosgene under ordinary conditions is a colourless, nonpersistent gas with an odour varyingly described as of musty hay, green corn or green apples. Tactically, it is classified as a casualty agent. At low temperatures it is a clear, colourless, mobile liquid, which boils at 8.3°C. Under ordinary summer conditions, it will disappear from a given locality about as fast as the wind moves. Even in winter it evaporates very rapidly. In a light wind an effective concentration of phosgene can readily be produced. It is used commercially for dye manufacture. During World War I it was first employed by Germany in Dec. 1915, in a cloud gas attack from cylinders.

Chloropicrin derives its name from its principal method of commercial manufacture by the action of chlorine on picric acid. When free of impurities, it is a nearly colourless liquid of waterlike appearance except for a slight oiliness. It has a characteristic sweetish odour somewhat like flypaper and usually is first detected by lacrimatory

effect on the eyes. It is a moderately persistent lung irritant but in addition causes lacrimation, nausea and vomiting. Tactically it may be classed as either a harassing or a casualty agent, depending on the concentration. Commercially, it is used as a seed fumigant and for insect control. Chloropicrin is said to have been first employed by Russia in 1916 and later was extensively employed by the Allies. It is neutralized by sodium sulphite solution in alcohol.

Mustard gas is a compound of carbon, hydrogen, sulphur and chlorine. It should not be confused with the true natural mustard oil or the artificial compounds having properties similar thereto. It was because of its sharp pungent odour and vesicant properties which resembled but greatly exceeded those of natural mustard oil that British soldiers first called it "mustard gas." The commercial product is a heavy oily liquid of dark colour and in low concentrations has the distinct odour of garlic or wild onions. This product freezes at about 10°C. It is one of the most persistent as well as one of the most toxic chemical agents. It is highly vesicant and is also a lung irritant. As the latter, in vapour form, after prolonged exposure, it attacks the whole respiratory system producing inflammation of the trachea and bronchi with necrosis of the mucous membrane and development of secondary bronchitis or bronchopneumonia. Upon slight contact with the liquid it is absorbed in the skin and produces serious burns. First employed by Germany at Ypres in July 1917, it was thereafter known to the French as Yperite. It hydrolizes slowly and may be neutralized by intimate mixture with bleaching powder, steam or gaseous chlorine.

Lewisite resembles mustard gas in many characteristics. It is a colourless or slightly yellow liquid freezing at —18.2°C. As usually prepared it is dark brown in colour with the faint odour of geraniums. Its vapour is distinctly irritating to the eyes and throat, sometimes followed by violent sneezing. It is absorbed by the skin or lung tissue and causes a serious blister. As it hydrolizes it liberates an oxide which poisons the body. It is a vesicant casualty agent, having a persistency of one to several days in summer and a week or more in winter. It is readily decomposed by water and may be neutralized by alcoholic sodium hydroxide spray. It was first made in the United States but has never been used in war. Lewisite has a distinct advantage over mustard gas in that blisters develop in about one hour, but has the disadvantage of rapid hydrolysis.

Hydrocyanic acid, though long known as one of the deadliest of compounds, was used with but little success during the period 1914–18. It is a paralysant acting vigorously on the central nervous system to produce quick death. Under ordinary conditions it is a colourless, mobile and volatile liquid with a slight odour of bitter almonds. It is a nonpersistent casualty agent. Because of its high volatility it is most difficult to maintain effective concentrations of hydrocyanic acid in the field; hence this compound has so far proven of little value in chemical warfare.

Diphenylaminechlorarsine, better known as adamsite, is representative of the large group of irritant smokes which may be used in war. Physically, in pure form it is a bright canary-yellow crystalline solid. Commercially, it is produced in a dark green or sometimes brownish colour. In solid state it is almost odourless, but when dispersed as an irritant smoke, a hazy yellow cloud is formed which gives a characteristic smoky odour. However, the first symptoms are usually a burning sensation in the nose and throat. It is classified as a nonpersistent harassing agent, but as such is extremely potent because very small concentrations with a brief period of exposure will prove effective. The headache, nausea and vomiting which it causes, followed by physical debility, render a person practically helpless. Effective use of the irritant smokes is largely dependent on penetration of the filtering device used with the gas mask. If protection is not assured, this group of agents has great potentialities in warfare.

White phosphorus, a pale yellowish, translucent crystalline solid of waxy consistency, is very active chemically and combines readily with oxygen. Hence unless protected from air it will burst spontaneously into flame. White phosphorus can be loaded into shell, bombs or grenades. When exploded by the bursting charge the solid phosphorus is broken into small fragments which are scattered in the air. The heat of explosion assists their immediate ignition, forming a cloud of phosphorus pentoxide. This smoke has the highest known obscuring power, yet is harmless when breathed. Fragments of considerable size are scattered about and continue to burn for some time, thus prolonging the emission of smoke. In addition, white phosphorus has limited incendiary value against readily combustible matter. Physiologically it may be classed as a casualty agent, since its ignited particles cause painful flesh burns that heal very slowly. Although primarily used for smoke production within the enemy lines, white phosphorus is also a formidable weapon against machine gun nests or troop concentrations.

FS, a mixture of sulphur trioxide about 55% and chlorosulphonic acid about 45% by weight, is an excellent cheap liquid smoke for release from containers or by dispersion from aeroplanes.

The thermits are mixtures of powdered aluminum and iron oxide which react chemically and generate intense heat. Hence they have powerful incendiary qualities and readily ignite any inflammable material. Allied to the thermits is the so-called electron bomb, used extensively in small scatter-type bombs during 1936–40 in Europe. This bomb has a case of magnesium alloy which is ignited by a chemical mixture and burns with intense heat.

Table I briefly summarizes characteristics of some important chemical agents used in war.

Protection.—Having in mind the three distinct types of agents employed in chemical warfare, protection is of interest principally as applied against gas, since smoke is harmless and protection against incendiary agents is limited to measures customarily followed in fire fighting. Against gas, protection has been highly developed. This type of defense is actually more effective than the protection that can be afforded against any other military weapon. In considering protection against war gases, it is necessary to distinguish between effect upon the respiratory organs and vesicant effect upon the body surface.

For protection against lung irritants, of which phosgene is typical, the gas mask is the primary protective device. The principle on which the military mask is based is that of filtering out or neutralizing noxious substances that may be present in inspired air. In order to accomplish this, air before it reaches the lungs must first pass through a filtering element containing materials that act mechanically or physically or react chemically with the toxic agents. For this reason a characteristic feature of the gas mask, from which its name is derived, is a tight-fitting facepiece so designed as to prevent air from reaching the respiratory organs from any direction except through the filter.

Since the mask must necessarily cover the entire face in order conveniently to permit normal respiration, it incidentally affords protection against lacrimators which, when the eyes are unprotected, cause intolerable eye irritation.

The principal materials used in gas mask filters (or canisters) are charcoal and soda lime. Charcoal absorbs and holds a relatively large volume of poisonous gases. Soda lime supplements the action of charcoal by neutralizing any toxic materials which might eventually be released by the charcoal and which otherwise would pass to the lungs with incoming air. Having a proper balance of charcoal and soda lime the gas mask may be worn with safety even after it has been used in concentrations of war gases

Besides soda lime and charcoal, masks are sometimes provided with mechanical filtration intended to strain out finely divided solid particles (toxic smokes), which severely irritate the nasal passages. The life of a gas mask filter depends on two factors: the length of time it has been exposed in gas attacks and the concentrations of gas that have been encountered. Military masks generally remain serviceable even after use in several gas operations When the capacity of the filter is approaching exhaustion a slight odour of gas can be detected. This indicates that replacement with a fresh filter is necessary.

Although it is possible to design filtering devices that will neutralize any toxic substance, it is not feasible to combine in one mask protection against all toxics. Military masks are accordingly constructed with a view to counteracting those particular chemicals that are thought most likely to be used in war. The introduction of new types of military gases in future will undoubtedly be followed by appropriate modification of masks now considered standard.

For safeguarding of personnel while sleeping, messing or otherwise engaged where the mask cannot be worn, gasproof installations are provided. These are known as gas shelters or collective protectors. A typical installation is equipped with a filter similar in principle to that used in the gas mask, although much larger. Incoming air is drawn through this filter and thus purified, other outside air being excluded, so that all air within the enclosure may safely be inhaled.

Protection by filtration applies only to those chemical-warfare agents that are dispersed as true gases and which are therefore injurious when breathed. Agents dispersed in liquid form, which attack the body through the skin surface, necessitate a different type of protection.

Against liquid chemical agents, of which mustard gas is typical, special protective clothing is utilized. To insure complete protection for persons obliged to remain in contaminated areas, fabrics used in this clothing must be treated with moisture-resisting compounds (*e.g.*, oilskins), and garments must be designed positively to exclude air at all points. The gas mask is invariably worn with protective clothing, to prevent inhalation of noxious fumes which are always present where liquid agents are released.

No effort is made to destroy nonpersistent or highly volatile gases, since these are eliminated in due course by dilution and dispersion. However, ground or other surfaces saturated by persistent (liquid) chemicals may be treated to hasten decomposition of toxic materials. Chlorine is most effective for this purpose and is commonly applied in the form of chloride of lime.

The effective use of antigas equipment is dependent on thorough military training and organization. Training establishes skill in the use of protective devices; in locating and identifying gassed areas; and in the selection of positions that lack vulnerability to gas attack. Gas defense organization, based on the assignment of suitable gas specialists to various units, insures attention to all features of chemical security, including such matters as the alerting of troops to gas attack and the degassing of areas contaminated with persistent chemicals.

All measures for protection against gas contribute toward the development of gas discipline. When this is high, military organizations are able to face gas attacks with confidence born of the knowledge that gas casualties will be light and that gas will not unduly impede the attainment of objectives.

First Aid Treatment.—When protective devices are not available, the prompt application of certain simple first aid measures will frequently prevent the development of serious injury from exposure to war gases.

In all such cases the first requirement is immediate removal from the gassed area. For lung irritant casualties, treatment is then directed to conserving the supply of oxygen, all of which is needed for natural recuperation. Thus complete relaxation and rest are essential; warming of the body with loose coverings and drinking of hot coffee are helpful. Patients are evacuated by litter and special precautions are taken to prevent exertion for some time, since fatalities are liable to occur even after a lapse of a day or more when preventive measures are not enforced.

Contact with liquid vesicants necessitates different treatment which, however, must be promptly initiated in order to avoid serious burns. All clothing which may have become contaminated is quickly removed and portions of the body contacted by the liquid agent are repeatedly swabbed as soon as possible with a solvent such as gasoline or alcohol. In lieu of the latter, scrubbing with soap and water is helpful Treatment administered as late as 30 minutes after exposure is seldom efficacious.

For the painful burns caused by contact of ignited fragments of white phosphorus with the skin, immediate relief is had by immersion in water. Application of an aqueous solution of copper sulphate enables the coated phosphorus particles to be removed, after which medical treatment is undertaken.

Lacrimation is soon counteracted by removal from the gassed area and exposure of the eyes to fresh air. From the effects of irritant smokes, relief is had by breathing low concentrations of chlorine and by flushing the nose with salt water or a weak solution of baking soda.

Protection of Civilian Population.—The potential threat of air-gas attack against congested population centres has forced wide adoption of protective measures for passive defense of noncombatants against chemical agents These measures are largely based on principles found effective for protection of military personnel. Gas masks designed for civilian use are ordinarily of lighter construction than those intended for use by soldiers in the field Gasproofed air raid shelters on the other hand are in most cases larger and more elaborate than are required for military operations. Civilian defense measures also include organization of medical aid for gas casualties, degassing squads and special fire-fighting units Civilian air-raid precautions in gas defense had become so highly developed and patently effective during the years immediately preceding 1939 as to assure a large degree of immunity from the effects of toxic gas in aerial bombardments of cities. To this fact may be ascribed, at least in a measure, failure to utilize chemical agents in the air attacks staged against European cities in 1939–40.

Dispersion of Agents.—With gas and smoke, military targets are areas rather than points against which fire of high explosives is usually aimed. Over these target areas the technique of chemical warfare is directed principally to establishing and maintaining an appropriate concentration.

The technical problems involved in dispersing chemical agents in war differ radically according to whether the medium employed is a volatile gas (or smoke) or a liquid. In the first instance it is necessary to generate an artificial cloud that will cover the selected area either (a) densely enough or (b) long enough to accomplish the desired result—since the effectiveness of chemical warfare agents is a product of two factors: concentration and length of exposure. The most efficient means for generating a gas or smoke cloud is by release from a stationary container (*e.g.*, cylinder). This was the method employed for the first use of gas in modern warfare (1915). It presents, however, certain practical disadvantages in military operations. A favouring wind is required to move the cloud to the target area, and where the distance the cloud must travel is very great the concentration will become unduly lowered before the target is reached. In order to overcome these difficulties, methods have been developed for projecting containers to the upwind side of distant targets and thus generating the cloud from a more advantageous position. This can be efficiently accomplished with smoke, but volatile gases do not lend themselves readily to dispersion at distances greater than 3,000 yards.

The principal methods by which volatile gases are dispersed, in the order of relative efficiency, are from (1) cylinders, (2) projectors, (3) shell. Efficiency of dispersion may be reckoned according to the ratio of the weight of the container to the weight of the agent it contains. This ratio is lowest for stationary cylinders, which can only be discharged within friendly lines. When the container is placed within a cannon and fired to the area of intended discharge it must necessarily be of heavier construction, its weight progressively increasing as weapons of greater range are employed.

The chemical projector discharges a container of relatively large volumetric capacity to ranges of approximately one mile. By employing a large number of these weapons in a single operation it is possible to establish effective concentrations of nonpersistent gas at some distance behind enemy lines.

The chemical mortar enables volatile gases to be released at distances of nearly 3,000 yd. But since the mortar projectile is much heavier, the proportion of gas it carries is accordingly lessened, thus reducing the size of gas cloud that can be established. On the other hand the chemical mortar can be fired repeatedly and the gas concentration can thus be maintained for a longer period than is possible with the projector.

The firing of nonpersistent gas containers from artillery weapons presents technical difficulties that have never been overcome nor have satisfactory aerial bombs been devised for this purpose. Liquid agents of the mustard gas type, however, may be employed in artillery of all calibres, the technique of firing being modified here to insure uniform distribution of impacts over the target area. The ideal shell for such use is of simple construction, designed to burst on or before impact so as to efficiently disperse the agent.

Aerial liquid-filled bombs may likewise be employed for dispersing persistent vesicants. Another effective method of aerial dispersion is that of sprinkling, where the agent is carried in tanks and discharged as a spray from low altitudes.

This represents possibly the most portentous form of chemical attack because the liquid chemical may thus be placed directly upon personnel.

TABLE I—*Characteristics of Some Important Chemical Agents Used in War*

Common name	Chemical name	Chemical formula	Physical state at 68° F. and 700 mm. pressure	Physiological effect	Elapsed time between exposure and effect	Lethal index (*) for mice and dogs (10 minute exposure)
Chlorine	Chlorine	Cl_2	Gas	Burns upper respiratory tract	Immediate; delayed in low concentrations	56,000
Phosgene	Carbonyl chloride	$COCl_2$	Gas	Causes lung oedema	Immediate	5,000
Hydrocyanic acid	Hydrocyanic acid	HCN	Gas	Paralysis of nerve centres	Immediate	2,000
Ethyldichlorarsine	Ethyldichlorarsine	$C_2H_5AsCl_2$	Liquid	½ as vesicant as mustard gas	30 min.	5,000
Chloropicrin	Trichlornitromethane	Cl_3CNO_2	Liquid	Burns respiratory tract. Lacrimates, causes nausea. Lung irritant	Immediate lacrimation; delayed lung action	20,000
Mustard gas	Bis Beta chlorethylsulphide	$(ClCH_2CH_2)_2S$	Liquid	Burns skin and lung tissue	4 to 24 hr.	1,500
Lewisite	Beta-chlorvinyldichlorarsine	$ClCH:CHAsCl_2$	Liquid	Burns skin and lung tissue, Arsenical poisoning in body	1 hr.	1,200
Adamsite	Diphenylaminechlorarsine	$C_6H_5NHAsClC_2H_6$	Solid	Headache, nausea, violent sneezing followed by temporary physical debility	5 to 10 min.	15,000
Chloracetophenone	Phenyl chlormethyl ketone	$C_6H_5COCH_2Cl$	Solid	Severe lacrimation and skin irritation	Immediate	8,500
Brombenzylcyanide	Brombenzylcyanide	$C_6H_5CHBrCN$	Solid	Severe lacrimation and nose irritation	Immediate	3,500
White phosphorus	White phosphorus	P_4	Solid	Incendiary effect	Immediate	
FM	Titanium tetrachloride	$TiCl_4$	Liquid	Eye irritation Prickly sensation on skin	Immediate	

*Product of the concentration (mg. per cu. m. of air) by number of minutes of exposure. These figures indicate the relative toxicity of war gases but do not necessarily represent their lethal effect on man. (After *A. M. Prentiss*)

Areas may also be contaminated by means of sprinklers operated from various types of vehicles. Another method applicable to delaying actions is by the use of land mines: tin containers which when statically detonated discharge their contents of liquid agent over the nearby ground.

The dispersion of smoke involves little deviation from the principles observed in the cloud-gas form of attack. The smoke cloud is in many tactical situations required for a longer period than may be the case with a gas cloud. Also with favourable wind conditions a much narrower screen of smoke will suffice to obscure vision. These factors make smoke well-adapted to discharge from artillery weapons. Liquid smoke agents (*e.g.*, titanium tetrachloride) may be discharged from aeroplane tanks, forming a smoke curtain that is of especial use in naval warfare.

Military Application.—The extent to which chemical warfare is employed in military operations may be said to depend principally upon its likely contribution to tactical success. Smokes and incendiaries have proven most valuable adjuncts to military force, so that these agents are commonly included in all modern armament. Gas on the other hand has been used but sporadically in battle after 1918, even though nonlethal types have found wide application in the control of domestic disturbances.

The casualties resulting from gas attacks made in Europe between 1915 and 1918 were impressive enough to justify regarding gas as a military weapon of considerable importance. However, the effectiveness with which gas may be counteracted by appropriate protective measures, which have been improved in recent years, introduces a factor that must be carefully evaluated in studying the possibilities of offensive gas warfare.

So long as antigas protection is highly maintained, the prospects for successful gas attack are materially lessened: when on the contrary gas defense is neglected, the gas weapon becomes one of exceptional potentiality.

The principal tactical value of the cloud-gas form of attack is in weakening defensive positions that successfully withstand assault. In warfare of continued movement this type of operation has limited value.

The most effective of all war gases is of the mustard gas type. This agent has important uses in both offensive and defensive action. The irritant smokes have definite possibilities when properly dispersed.

None of the gases so far employed in warfare satisfies the ideal of a substance, the use of which will permit an army to easily subjugate an opposing force.

The quest for such an agent may be unending, yet meanwhile the possibilities of chemical warfare will continue to receive close study.

Gas Warfare.—Gas (or chemical agents), which proved to be a weapon of considerable importance in military operations in World War I, was not employed during World War II. Only after the occupation of Germany and Japan by Allied forces in 1945 was the situation as to gas warfare in these countries fully disclosed. With data available, reasons why gas was not resorted to in World War II become clear.

Preparations made by Germany for gas warfare were found to have been extensive. The tonnage of chemicals produced by German chemical plants between 1939 and 1945 exceeded by nearly 50% the total amounts produced during World War I. Captured ammunition dumps contained large stores of gas-filled shells and bombs. Some were loaded with a new war gas while two more highly toxic agents had been discovered and were being processed for production.

Thus, Germany had at its disposal a powerful military weapon which was never brought into action, even in time of dire need. The official explanation given at German gas defense schools for this fact was that Hitler did not approve the use of gas. However, more cogent reasons deterred Germany, even though it was true that Hitler never put the weight of his authority behind the development of chemical warfare.

From the viewpoint of tactics, gas was inappropriate to the early stages of the war when German ground and air forces were most capable of employing it effectively. Later, when gas promised high tactical advantage, Germany had lost aerial supremacy over the reich and for this reason stood to lose on the strategic side any gains that might be made tactically.

To the German high command there was obviously no profit in releasing gas on the beach at Anzio if this meant retaliatory showering of chemical bombs on German cities.

Behind reasons of immediate military expediency other deterrents were also at work. Allied armies were well prepared, in both training and equipment, for defense against gas attack. At the same time Great Britain and the U.S. possessed ample stocks of gas-charged aerial bombs which were known to be located within striking distance of Berlin. Thus, the elements of surprise and preponderant initial advantage were denied Germany. The result was a situation of stalemate which the nazis seemed perfectly satisfied should continue while the attention of German scientists was being directed toward military novelties of apparently greater promise.

Japan, which had never been a serious contender in the field of toxic chemicals, was found to run a poor second to Germany in this connection. Japanese armament could have permitted only face-saving retaliation against a first-class power undertaking large-scale gas warfare. Emphasis was, therefore, placed on gas defense and on authoritative assurance "that Japan has never used, and never will use, gas against any enemy, unless the fact that the enemy has . . . is definitely established."

The Allies were in position to apply the pressure of gas to sensitive points almost at will throughout most of World War II. There were several occasions when such pressure could have been utilized to both tactical and strategical advantage. This can scarcely be said of either Germany or Japan. The Allied show of force in the field of gas warfare was, therefore, demonstrably in support of a firmly announced policy of the Allies to discourage the employment of this weapon.

The strong presentation of this policy to the Tokyo government by President Roosevelt in June 1942, which evoked the declaration above cited, resulted also in immediate cessation of incidents of Japanese use of gas on the Chinese mainland which up to that time had been reported with frequency. As the war progressed Japan adopted vigorous measures to avoid occasions which might even suggest intention to employ gas. Imperial directives were issued to field commanders forbidding use of toxic chemicals under all circumstances unless specifically ordered by highest authority.

In Germany, also, careful attention was given to avoidance of untoward events which might precipitate gas operations. Chemical troops carried only smoke-filled projectiles. Toxic munitions, which accumulated in considerable quantities toward the end of the war, were stored well inside the country; even stocks possessed by satellite nations were found to have been transferred to depots in central Germany. The nazi decision not to use gas was certainly not based on lack of ammunition.

The gas warfare policy of the Allies (with which the prewar unilateral policy of the U.S. coincided) left initiative entirely to the opponents. Attendant circumstances, however, were such as to make it inadvisable to accept this initiative. The future use of gas as a military weapon must be read in the light of this basic fact.

Chemical agents of toxicities greater than those known in 1918 were available for World War II. Development of air power, moreover, had greatly enhanced the capabilities of gas warfare. Thus, despite remarkable advances made with other weapons, gas was still to be rated as a relatively powerful instrumentality of war.

Whether or not this potentiality will actively be employed in the future is largely a question of whether the policy as to nonuse of the gas weapon can be continued in force. Measures that have so far sustained this policy are strong offensive preparations coupled with effective defensive procedures, both backed by extended research and production. During World War II the United States spent prodigious sums for these purposes; yet the results of such expenditures can be accepted as profitable.

At least it may be accepted, based on experience in the field of gas warfare, that peace-loving nations can possess a powerful military weapon and at the same time approach its use on grounds higher than those of military expediency. Thus, there is good reason to believe that the atomic bomb as well as gas will eventually prove to be a self-inhibiting agency of war.

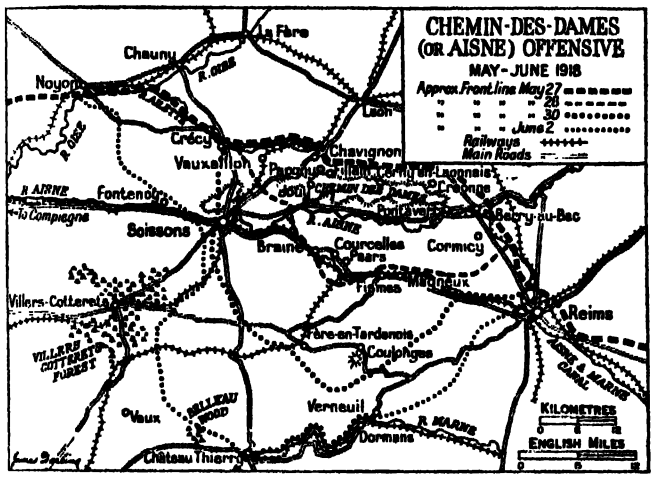
CHEMILUMINESCENCE is cold light of chemical origin. This includes all forms of radiation—whether visible, infra-red or ultra-violet—emitted in excess of the black body radiation so far as the energy is supplied from simultaneously occurring chemical reactions.

Chemiluminescence is most commonly generated by oxidation. A large number of substances, such as formaldehyde, dioxymethylene, paraldehyde, acroleine, lophin, glucose, lecethin, cholesterin, luminesce if slowly oxidized in alkaline alcoholic solution (Br. Radziszewski, 1877–83). Another group of chemiluminescences described by M. Delépine (1910–12) is connected with the oxidation of sulphur compounds. The chemiluminescence of siloxene (H. Kautsky, 1921–25) is of special interest since its study has thrown much light on the mechanism of chemiluminescence. The widespread luminescence of living organisms like fireflies and luminous bacteria has been shown by R. Dubois (1885–87) to be based on the oxidation of a thermostable substance of unknown structure, luciferin, in the presence of a thermolabile enzyme, luciferase.

The light emitted in chemiluminescence can usually be ascribed to the transfer of the energy of oxidation to a molecule not itself undergoing oxidation in which light is thus generated. The chemiluminescence of siloxene, for example, was shown to be caused by



the emission of light by unoxidized siloxene particles, and that of living organisms to light emission by unoxidized luciferase particles.

A chemiluminescent reaction which can be analyzed in detail is that between sodium vapour and the halogens or halogen-containing molecules such as $HgCl_2$ (M. Polonyi and collaborators, 1925–30). The halogen is introduced through a nozzle into a space containing sodium vapour, pressures being about 0.01 mm. Emission of the yellow D-line of sodium occurs with an efficiency (=number of light quanta per number of reacting molecules) which may rise to near unity for chlorine. The reaction with halogens (X_2) proceeds through $Na+X_2=NaX+X$ followed by a reaction of the halogen atom X with sodium vapour. The luminescence is caused by the transfer of the energy of the reaction $Na_2+X=NaX+Na$ to an Na atom which emits its characteristic radiation, the D-line. (*See* FLUORESCENCE AND PHOSPHORESCENCE.)

CHEMIN-DES-DAMES, BATTLE OF THE, 1918.

This is the name commonly given to the May offensive of the Germans in 1918, the third act of their plan to reach a military decision before the weight of U.S. numbers could turn the scales against them. It is alternatively called the Battle of the Aisne, 1918, or, less frequently, the Battle of Soissons-Reims. After

PLAN OF THE THIRD PHASE OF THE FINAL GERMAN OFFENSIVE IN 1918
The German attack, launched May 27 on a 30 mile front, took the Allies by surprise and drove them across the Aisne to the Marne. There, German efforts to push westward failed

the relative failure of the German offensives of March and April it was essential for the Germans, if they wished to preserve the initiative, to deliver another powerful blow without delay. The choice of the front of attack and the battleground fell on the oft-contested chain of heights between the Ailette and the Aisne, the Chemin-des-Dames.

Dispositions for the German Attack.—The German supreme command had decided to attack with the 7th and 1st armies against the sector between north of Soissons and Reims. If this attack proceeded favourably, it was to be prolonged on the right over the Ailette to the Oise and on the left as far as Reims. The German supreme command hoped that the push southward would succeed in reaching the neighbourhood of Soissons and Fismes, and by this means attract strong forces from Flanders so that it might be possible to continue the attack there according to plan. Preparations began about the middle of May. The 7th army under Böhm was charged with the main attack across the Chemin-des-Dames, the 1st army under Below with the neighbouring attack on the left in the direction of Compiègne. The right wing of the main attack, the 54th corps and the 8th Res. corps, had the task of pushing forward in a southwesterly direction on both sides of Soissons. The 25th Res. corps was to strike on both sides of Cerny-en-Laonnais direct toward Braisne, and on the east to take as much country as possible toward the south; the 4th Res. corps was to attack the high ground at the eastern end of the Chemin-des-Dames, immediately north of Craonne; in concert with this on the left the 65th corps was to occupy with its left wing the river bend north of Berry-au-Bac. Of the 1st army only one corps was to be launched at the outset to throw the opposing forces over the Aisne-Marne canal. The corps was to provide itself with bridgeheads in order to take the heights of Cormicy if the attack of the 7th army proceeded favourably.

For success there were two essentials; the first, surprise and the second, effective artillery preparation. Most elaborate and thorough precautions were taken to secure secrecy. As regards artillery preparation the ascent of the steep slopes on the heights of the Chemin-des-Dames was only possible if the Germans should succeed in silencing the bulk of the opposing guns. All registration was to be abandoned in order to surprise the enemy as much as possible. The first aim was to be a thorough gassing of the Allied position right down into the Aisne valley. Preparations were completed by the evening of May 26, 1918. At that moment four battle-worn British divisions were resting in this supposedly quiet sector. They had been sent to the French front, after strenuous exertions in the battles of the Lys, in return for French reinforcements which had gone north to the aid of the British in the later stages of that "backs to the wall" struggle. On the tranquil Aisne they could recuperate, while still serving a useful purpose as guardians of the trench-line. It was too quiet to be true. But the uneasiness of the local British commanders—shared by certain of their French neighbours—was slightly discounted by their Allied superiors. On May 25 they received from French headquarters the message that "in our opinion there are no indications that the enemy has made preparations which would enable him to attack to-morrow."

At 1 A.M. on May 27, 1918, a terrific storm of fire burst on the Franco-British front between Reims and north of Soissons, along the famous Chemin-des-Dames; at 4:30 A.M. an overwhelming torrent of Germans swept over the front trenches; by midday it was pouring over the many unblown bridges of the Aisne, and by May 30 it had reached the Marne—site and symbol of the great ebb of 1914. Happily, it proved to be "thus far, and no farther." Like the two great preceding offensives of March 21 and April 9, that of May 27 achieved astonishing captures of ground and prisoners, but it brought the Germans little nearer to their strategical object. And, even more than its predecessors, its very success paved the way for their downfall. To the reasons for this we shall come. But why, a month after the last onslaught, in the north, had come to an end, why, when there had been this long interval for preparation and for examination of the situation by a now unified command, should a surprise greater than any before have been possible?

It has long been known, of course, that the French command, that directly concerned with the safety of this Aisne sector, did not believe in the likelihood of an attack. Nor did the British higher command, which, however, was personally concerned with the front in the north. But the intelligence of another of the Allies, better placed to take a wide survey, did give the warning—only to be disregarded until too late. On May 13, a fortnight after the fighting in Flanders had died away, the British intelligence came to the conclusion that "an attack on a broad front between Arras and Albert is intended." Next day this was discussed at a conference of the intelligence section of the American Expeditionary Force, and the head of the battle order (of the enemy) section gave a contrary opinion holding that the next attack would be against the Chemin-des-Dames sector, and between May 25 and 30.

The warning in detail was conveyed to the French general headquarters, but fell on deaf ears. Why should credence be given to an opinion coming from such a new army, not yet tested in battle, over the verdict of war-tried and highly-developed intelligence services? The warning was reiterated, however, and the French intelligence was won over to its acceptance. But now, as at Verdun two years before, the operations branch opposed until too late the view of its own intelligence. This time, how-

ever, it was less blameworthy, for it was tugged the other way by the comforting assurances of the commander of the 6th French Army, in charge of the Chemin-des-Dames sector. This general, indeed, had a still heavier responsibility, for he insisted on the adoption of the long-exploded and wasteful system of massing the

er, the German infantry would find practically no local reserves to oppose their progress through the rear zones. In similar manner all the headquarters, communication centres, ammunition depots and railheads were pushed close up, ready to be dislocated promptly by the enemy bombardment.

Pétain's instructions on a deep and elastic system of defense had evidently made no impression on this army command, so that it was still less a matter for wonder that the protests of junior British commanders met with a rebuff. It was unfortunate, also if perhaps less avoidable, that when the four British divisions forming the 9th corps (Hamilton Gordon) arrived from the north at the end of April, their depleted ranks filled up with raw drafts from home, they were hurried straight into the line, as the best place to complete their training. The backbone of the Aisne defenses was formed by the historic Chemin-des-Dames ridge north of the river. The eastern half of this "hog's back" was to be held by the British, with the 50th division (Jackson) on the left, next the 8th division (Heneker), and, beyond the end of the ridge, in the low ground from Berry-au-Bac along the Aisne and Marne canal, the 21st division (Campbell), joining up with the French troops covering Reims. The infantry of the 25th division (Bainbridge) was in reserve.

Altogether the French 6th army front was held by four French and three British divisions, with three and one respectively in reserve. Against these tired or raw troops, in the main attack from Berry-au-Bac westward, 15 German divisions, all but one brought up fresh, were to fall upon five, with two or more for the subsidiary attack between Berry-au-Bac and Reims, while 7 German divisions lay close up in support. Even so, the German superiority was not so pronounced as in the March and April offensives, whereas both the rapidity and the extent of their progress were greater. Yet this time the tactical surprise of the assault was unaided by the heavy ground mists which had previously helped so much by wrapping their initial advance in a cloak of invisibility. The conclusion is, therefore, that the advantage was in part the result of the strategic surprise—the greater unexpectedness of the time and place—and in part to the folly of exposing the defenders so completely to the demoralizing and paralyzing effect of the German bombardment—by 3,719 guns on a front of under 40 mi. This last, indeed, was a form of surprise, for the object of all surprise is the dislocation of the enemy's morale and mind, and the effect is the same whether the enemy be caught napping by deception or allows himself to be trapped with his eyes open.

For three and a half hours, on May 27, the unfortunate troops had to endure a bombardment of exceptional intensity. And the ordeal of those hours of helpless endurance, amid the ever-swelling litter of shattered dead and untended wounded, was made more trying by crouching, semi-suffocated in gas masks. Then the gray waves advanced—relief, if only of action, at last. Three-quarters of an hour later they had reached the crest of the ridge in the centre near Ailles. This uncovered the flank of the left British division, the 50th, forcing its survivors to fall back down the other slope. Next to it, the 8th division was being forced to give way, although two of its brigades held on stubbornly for a time on the north bank of the Aisne. On the British right, the attack on the 21st division developed later; this division was awkwardly placed with the swampy Aisne and Marne canal running through the centre of its battle zone, but most of it was successfully extricated and withdrawn west of the canal. By midday the situation was that the Germans had reached and crossed the Aisne at most points from Berry-au-Bac to Vailly—helped by the fact that the order to blow up the bridges had been given belatedly. Hitherto the German progress had been evenly distributed, but in the afternoon a heavy sagging occurred in the centre, at the junction of the French and British wings, and the Germans pushed through as far as Fismes on the Vesle. This was natural, both because the joint is always the weakest point, and because the heaviest weight—more than 4 to 1—of the assault had fallen on the two French divisions in the centre and the left

pressure, compelled a drawing back of the [illegible], or British flank, this operation was distinguished by a remarkable manoeuvre of the 21st division, wheeling back during the night through hilly, wooded country, while pivoting on and keeping touch with the Algerian division, which formed the right of the army. After a pause in the morning of May 28, the Germans forced the passage of the Vesle, and on the 29th they made a vast bound, reaching Fère-en-Tardenois in the centre, and capturing Soissons on the west, both important nodal points, which yielded them quantities of material. The German troops had even outstripped in their swift onrush the objectives assigned to them, and this, despite the counterattacks which Pétain was now shrewdly directing against their sensitive right flank. On the 30th the German flood swept on the Marne, but it was now flowing in a narrowing central channel, for this day little ground was yielded by the Allied right flank, where the 19th division as well as French divisions had come to reinforce the remnant of the original four British divisions, which next day were relieved.

From May 31 onward the Germans, checked on the side of Reims and in front by the Marne, turned their efforts to a westward expansion of the great bulge—down the corridor between the Ourcq and the Marne toward Paris. Hitherto the French reserves had been thrown into the battle as they arrived, in an attempt to stem the flood, which usually resulted in their being caught up and carried back by it. On June 1, however, Pétain issued orders for the further reserves coming up to form, instead, a ring in rear, digging themselves in and thus having ready before the German flood reached them a vast semicircular dam which would stop and confine its now slackening flow. When it beat against this in the first days of June its momentum was too diminished to make much impression, whereas the appearance and fierce counterattack of the 2nd U.S. division at the vital joint of Château-Thierry was not only a material cement, but an inestimable moral tonic to their weary allies. In those few days of "flooding" the Germans had taken some 65,000 prisoners, but whereas this human loss was soon to be more than made up by U.S. reinforcements, strategically the Germans' success had merely placed themselves in a huge sack which was to prove their undoing less than two months later (*see* MARNE, SECOND BATTLE OF THE). As in each of the two previous offensives, the tactical success of the Germans on May 27 proved a strategical reverse, because the extent to which they surprised their enemy surprised and so dislocated the balance of their own command.

As the disclosures of General Kuhl have revealed, the offensive of May 27 was intended merely as a diversion, to attract the Allied reserves thither preparatory to a final and decisive blow at the British front covering Hazebrouck. But its astonishing opening success tempted the German command to carry it too far and too long, the attraction of success drawing thither their own reserves as well as the enemy's. Nevertheless it is a just speculation as to what might have resulted if the attack had begun on April 17, as ordered, instead of being delayed until May 27, before the preparations were complete. The Germans would have worn out fewer of their reserves in ineffectual prolongations of the Somme and Lys offensives, while the Allies would have still been waiting for the stiffening, moral and physical, of U.S. manpower. Time and surprise are the two supreme factors in war. The Germans lost the first and forfeited the second by allowing their surprise to surprise themselves. (B. H. L. H.)

CHEMIST, one who, for pleasure or profit, concerns himself with the acquisition of information relating to the composition and structure of substances and the changes of composition and structure which they undergo. The chemist traces his evolution from the Greek philosophers, who speculated without experiment

as to the constitution of matter, through the mediaeval alchemists, who experimented with little logic, in the hope of transmuting one element into another. During the middle ages another sect, the iatrochemists, also existed, who carried out experiments which were to make chemistry more useful to medicine. Many types of chemists exist, classed usually according to the kind of matter or the kind of change with which they are most concerned. When the individual applies his information to the production, manufacture or commercial use of commodities, he is customarily considered an industrial chemist or chemical engineer.

CHEMISTRY. The science that is concerned with the composition of bodies and with the changes of composition they undergo. Analytical chemistry deals with the methods of separation of purer substances from mixtures, of elements from compounds, and with their estimation; synthetic chemistry treats of the methods by which complex bodies may be built up from simpler substances. In each case it is the changes of composition that concern the chemist. The combination of atoms, and the arrangement of atoms in a molecule, used to be regarded as the special province of the chemist; while the physicist dealt with changes of state and with the motions of the molecules: but today this distinction cannot be maintained.

With the rapid growth of modern chemistry it has become the practice to divide the theoretical study of the science into three main branches, and this conventional division is adopted in the present article, which, in addition, contains sections dealing with the history of chemistry and the practice of chemical analysis:—*History of Chemistry; Inorganic Chemistry; Organic Chemistry; Physical Chemistry; Analytical Chemistry* (*Inorganic Analysis, Ultimate Organic Analysis, Gas Analysis*).

HISTORY OF CHEMISTRY

Chemistry as a science had its origin in Egypt (*see* ALCHEMY) the product on the one hand of much practical experience of workers in metals, glass and pottery, of users of dyeing and tanning materials; and on the other of Greek and Eastern speculation on the nature of the material world. The great school founded at Alexandria was the natural meeting place of the two streams, and from their union came in time the alchemy of the Arab conquerors, the iatrochemistry (*q.v.*) of the medical chemists and finally our modern science. In all the older cosmogonies we find the idea that there was some primordial element or principle from which the visible universe was derived. Perhaps the oldest speculations assigned to water this elementary character; its teeming life, its vivifying power, its solid deposits all marked it as the origin of things. The doctrine that water was the prime element—associated with the name of Thales—exerted an immense influence on scientific thought throughout the centuries. John van Helmont in the early 17th century thought he had proved it experimentally; it remained for Antoine Lavoisier in the late 18th to disprove it by mere decisive experiment. But water was not the only "element" that was regarded as primordial by Greek philosophers. That air could be condensed into clouds and clouds into rain was taught by Anaximenes; water could be evaporated into air, leaving solid earth behind. Everything therefore sprang from air. That fire was the first principle of things would appeal to those who came in contact with the fire worship of the Chaldeans, or with the religion of the Persians and Parsees, whom Zoroaster taught to look on fire as the symbol of goodness in creation. Heracleitus among the Greeks espoused the cause of fire, Pherecides that of earth; it was indeed easy to show that from combustible solids fire, air and water could be derived. That all four were primal elements, and that the varieties of matter were made from intermixture of these, was the conception of Empedocles, who regarded each element as distinct and unchangeable. But the doctrine of the four elements which gave so powerful an impulse and direction to chemistry was that taught by Aristotle. The importance of his doctrine lay not so much in the nature he assigned to matter, or to the modes in which qualities might be affixed to it, but in the broad principle that one kind of matter could be changed into another kind—in a word, that transmutation was possible. Underlying all tangible bodies was an indeterminate matter-stuff (ὕλη) on which properties might be impressed giving matter its particular form (εἶδος).

If such fundamental qualities as hotness and dryness (or their opposite qualities, coldness and wetness) are impressed on the matter-stuff, we may conceive two qualities combining to give a primal form of matter. For instance, the combination of dryness with heat gives fire, with cold gives earth: the combination of wetness with heat gives air, with cold gives water. Moreover these qualities are not unalterable. If the coldness of water is overcome by heat, the water changes to steam or air; if its wetness is overcome by dryness it leaves earth.

Aristotle's conception differed therefore not only from the unchangeable elements of Empedocles, but from the mechanical hypothesis of Democritus, who imagined the world built up by the fortuitous meeting of rapidly moving atoms—themselves of unalterable nature.

In Egypt the Aristotelian doctrine of the four elements readily took root. Working in metals had been practised for centuries not only along the valley of the Nile, but in the valleys of the Euphrates and the Indus, between which there had long existed intercourse.

How far the teaching of the Alexandrine school directly affected chemical practice among the Egyptians is doubtful. It is clear from the chemical writings that have been preserved—especially from the famous papyrus at Leyden—that the priests were well acquainted with methods for imitating gold and silver, and for covering metal vessels superficially with gold alloys so that the base metal could be removed and leave a pure gold surface which would "pass the test."

ALCHEMISTS AND IATROCHEMISTS

When the Arabs conquered Egypt in the 7th century and overran Syria and Persia, they brought a new spirit of enquiry to bear on the old civilizations they subdued. The great name that stands out in the alchemic period is that of Jabir—probably the same Geber of the Latin books *Summa Perfectionis* and *Liber Fornacum* of which the existing manuscripts date from the 13th century. Jabir ibn Hayyan accepted the Aristotelian doctrine of the four elements, but to these he added the special chemical elements mercury and sulphur, by which he meant not so much the two elements as met with in nature, but rather the principles giving metals their unalterable property, and the earthly impurity that it was possible to cleanse them from. Gold, unaltered by fire, contained a very pure mercury; lead and copper contained much sulphur. That gold could be extracted from copper pyrites, and that silver remained when galena was long roasted, were regarded as evidence that the lustrous crystals of pyrites and galena, looked on as metals, had been transmuted by purification from the sulphur or dross into the nobler metals.

The two alchemic elements were thus introduced; the third element "salt"—representing the residue that remained fixed after calcination—was added by the iatrochemists. These three elements constituted the *tria prima* of Paracelsus and his disciples of the 16th century. Jabir himself seems to have believed in the philosopher's stone, and the term Kimya may have signified the secret powder which had to be projected on the molten metal to cause transmutation.

A century after Jabir came Rhazes, physician and chemist; and he was followed by Ibn Sina, better known as Avicenna, who knew that metals could be changed in colour, but not really altered in substance.

In the 11th century Mansur distinguished between *natron* (sodium carbonate) and *qali* (potassium carbonate). He describes the preparation of a plaster of Paris, for use in surgery, by heating gypsum and mixing it with white of egg.

When the Arabs penetrated into Spain they brought with them their chemical knowledge and their love of learning. Through the Arab universities founded in Spain, the knowledge not only of alchemy, but also of much of Greek thought first illuminated the backward states of Europe. We cannot be sure of the origin of many of the Latin texts of the 12th and following centuries. It is said that the book translated from the Arabic by Robert of

Chester in 1144 contains passages which occur in the earlier alchemist manuscripts. It is even probable that the names which figure largely among the early chemists in Europe—Albertus Magnus, Roger Bacon, Raymond Lully, Vincent de Beauvais—are those of writers who made known not so much their own chemical experience as that of the Arabian alchemists. Albertus takes the same view as Avicenna concerning "chemical gold"—it is a superficial imitation, not real gold.

Paracelsus, the son of a physician, studied at Basle and at Würzburg, and after wandering through Europe returned to Basle in 1526 and was appointed professor of medicine. His first public act was to burn the works of Galen and of Avicenna, the great handbooks of medicine, and to proclaim that chemistry was not concerned with the transmutation of metals but was the handmaid of medicine. His reckless use of inorganic salts—many of them poisonous—led to his expulsion from Basle.

Contemporary with the restless and dogmatic Paracelsus, Agricola devoted many years to the study of ores and the preparation of pure metals and salts from them. His *De Re Metallica* records many first-hand experiments—on the amalgamation process of extracting gold, on the properties of bismuth, on flame-tests for various metals. A little later Libavius, a German physician, published his *Alchymia*, which may be regarded as the first European textbook of chemistry. Coming later still, Glauber made his reputation as a great practical chemist: he gave a clear description of the mineral acids and of *aqua regia* (*q.v.*), and he left his name attached to sodium sulphate.

Last of the iatrochemists came van Helmont, regarded by many as the link between the alchemists and the modern chemists. He rejected the *tria prima* of Paracelsus and the four elements of Aristotle, going back to the older doctrine of Thales that water was the origin of all things. His well-known experiment of growing a willow-shoot in dried earth, and watering it regularly until it had gained many pounds in weight without receiving any appreciable nutriment except from the water, is recalled now with a feeling that Nature had a sense of irony in deceiving the man who discovered carbonic acid gas.

He showed that an air was given off when an acid acted on limestone or potashes, and that this air extinguished a flame. The same air he found was produced in fermentation and occurred naturally in the Grotto del Cane. In his endeavours to prepare the air in closed vessels he discovered the enormous force developed by it; *Ideo, nominis egestate,* he writes, *halitum illum Gas vocavi, non longe a Chao veterum secretum* (*Opera Omnia,* Frankfurt, 1682, p. 69). The term *gas sylvestre,* applied to carbon dioxide, meant the wild chaotic air that could not be coerced into vessels. Van Helmont found he could make an inflammable air, *gas pingue,* by heating animal matter, but he did not further distinguish between his gases.

BIRTH OF MODERN CHEMISTRY

Boyle.—A new era began with Robert Boyle. In early life, a member of the "Invisible College" (the germ from which the Royal Society sprang), he was drawn in 1654 to Oxford where several of the members were in residence. Here he spent his most active years in experimental research. He established by careful experiments the law known by his name—that the volume of a given mass of air varies inversely as the pressure upon it. He determined the density of air and pointed out that bodies altered in weight according to the varying buoyancy of the atmosphere; and he compared the lower strata of the air to a number of sponges or small springs compressed by the weight of the layers above them. It is notable that not only the facts published by Boyle on the "Spring of the Air," but the very images he used were repeated by Edmè Mariotte 14 years later.

In 1661 Boyle published the *Sceptical Chymist,* in which he gravely questions the *tria prima:* "There are some bodies from which it has not yet been made to appear that any degree of fire can separate either salt, or sulphur or mercury, much less all three. Gold may be heated for months in a furnace without losing weight or altering, and yet one of its supposed constituents is volatile and another combustible. Neither can solvents separate any of the three principles from gold; the metal may be *added to,* and so brought into solution . . . but the gold particles are present all the time: and the metal may be reduced to the same weight, of yellow, ponderous malleable substance it was before."

Boyle gives many instances in which metals, such as lead or copper, may be dissolved in acids and their properties entirely disguised in the compound. The corpuscles of which the metal is composed, meeting with corpuscles of another kind, may be more disposed to unite with them than with the particles forming their original metallic cluster. From the coalition of two different corpuscles a new body may be formed "as really one as either of the corpuscles before they were confounded." We can trace here the modern idea of chemical affinity uniting atoms into compounds. Boyle devised a method for extracting the element phosphorus, which was long known as Boyle's phosphorus; he made many experiments on air and other gases. He prepared hydrogen by the action of acids on steel filings and on iron nails, and showed that it would burn with a strong flame though with little light. He collected the gas in an inverted glass flask over dilute acid, and showed that the imprisoned gas was permanent and "dilated itself" like air when the vessel was warmed.

In his "New Experiments touching the Relation betwixt Flame and Air" he showed that the flames of hydrogen, of sulphur, and of a candle were extinguished in the receiver of his air pump when the air was rarified. But, finding that gunpowder and fulminating gold would burn in his vacuum, he was forced to conclude that flame may exist without air: it was left to his assistant Robert Hooke to make the next advance.

By observing that wood charcoal was immediately dissipated into white ashes if the retort was opened in the air while still red-hot, Hooke grasped the fact that the air "preyed upon" or "dissolved" the charcoal; and he compared the active constituent of the air with that which is fixed in saltpetre. The oil rising as vapour from a lighted wick is not burnt inside the flame (which is dark) but only as it reaches the surrounding atmosphere where it meets the "nitre-air."

John Mayow made careful experiments on the burning of combustible bodies in air confined over water. He showed that part of the air disappeared both in combustion and respiration, and that the residue left would not support flame or life. This residue differed then from ordinary air. He did not isolate his nitre-air, nor show what became of it.

THEORY OF PHLOGISTON

The theory of phlogiston first proposed by Johann Joachim Becher and greatly advanced by Georg Ernst Stahl went back to the old idea of Jabir that combustible bodies lost something when they burnt. Becher's *terra pinguis* became Stahl's phlogiston, which was not fire itself but the material of fire. Metals were composed of a *calx,* different for each metal, combined with phlogiston, which was the same in all metals and common to all combustibles. When a metal, such as lead or tin, was calcined in the air, phlogiston was evolved and a calx was left behind. When a candle or charcoal was burnt in the air it gave off phlogiston (manifest as heat and light) and very little residue was left: wax and charcoal mainly consisted of the material of fire. When a calx was heated with charcoal out of contact with air the phlogiston of the charcoal recombined with the calx and the metal was regenerated. In this way a generalization was made which accounted for the two opposite processes of oxidation and reduction, and moreover was able to predict certain chemical consequences which were verified later by experiment. The heat given off by animal bodies and its restoration by food were also explained by phlogiston. The fact that combustion and life ceased in a confined volume of air was due to the swift whirling motion of the phlogiston that filled the air, which when saturated could take no more. In considering the wide acceptance of Stahl's theory it must be borne in mind that it gave expression to the very striking facts that in combustion something was emitted by the burning body, viz., *heat,* and in the reduction of a calx by charcoal something—potential energy, or the power of giving out heat again—was restored to it.

ANTIPHLOGISTIC EXPERIMENTS

Black and Cavendish.—The first blow to the phlogistic theory was dealt by Joseph Black, himself an adherent. It had long been known that limestone was turned into quicklime by heating, and that quicklime brought into contact with the mild alkalis rendered them caustic, returning itself to chalk. This was explained by supposing that the fire gave a "burning principle" to the limestone, which handed it on in turn to the mild alkali. Black, using the balance, found that both chalk and magnesia alba lost weight when they were heated, the loss being due to the escape of a gas previously fixed in them. The caustic lime and magnesia, freed from the gas, no longer effervesced with acids: moreover, the chalk and magnesia alba lost the same weight of gas whether they were strongly heated or were dissolved in an acid. The effervescence was obviously due to the escape of the air. Then an aqueous solution of the caustic lime or magnesia when exposed to the atmosphere gradually formed a white precipitate and lost its causticity as the "fixed air" from the atmosphere dissolved in the surface layer of the liquid. Caustic lime and magnesia act on the mild alkalis by combining with their fixed air, and not by an exchange of phlogiston. Black had proved by quantitative experiments the difference between the mild and caustic alkalis, and had shown that fixed air (CO_2) was a normal constituent of our atmosphere (1756).

Twenty years later Henry Cavendish published his researches on "Factitious Air," in which he described the preparation and properties of carbon dioxide and hydrogen. His work on hydrogen is of the first importance. "Inflammable air," he found, could be produced readily by the solution of zinc, iron and tin in dilute sulphuric or in hydrochloric acid. He collected and measured the gas over water, and found that a given weight of one of the metals gave the same measure of gas whichever acid was used as the solvent and however diluted the acid. He concluded therefore that the gas came from the metal and was either phlogiston or a compound of phlogiston with water.

Informed of Joseph Priestley's observations that in the explosion of inflammable air with common air a dew was deposited on the vessel and a loss of weight ensued, Cavendish carefully repeated the experiments and showed there was no loss of weight, while "almost all the inflammable air, and about one-fifth part of the common air, lose their elasticity and are condensed into a dew which lines the glass." He then burnt a quantity of hydrogen in air and, collecting the dew, found it had the properties of water; the two airs, he said, "are turned into pure water." Then Cavendish fired a mixture of hydrogen and oxygen, and was puzzled for some time by finding the condensed water to be acid. He proved this acid was caused by the presence of adventitious nitrogen (from the air) which was acted on in the explosion if the oxygen was in excess. Afterward he passed electric sparks through a mixture of air and oxygen in a bent tube over mercury in presence of potash. In this remarkable experiment he not only proved the composition of nitre, but proved that the nitrogen of the air could be completely removed with the exception of a small inert bubble of gas about one $\frac{1}{120}$ part of the whole. He had isolated argon (*q.v.*) from the air—by the same method used by Rayleigh and Ramsay more than 100 years later. Much has been written regarding the relative claims of Cavendish, Watt and Lavoisier regarding the discovering of the composition of water. It would seem clear that Cavendish alone established this by his exact quantitative work. Claims on behalf of James Watt have been advanced for having given the correct interpretation of the experimental results. Lavoisier is not entitled to any share in this discovery—his merit rests upon having expressed the results in language unhampered by the phraseology of the phlogistic theory of combustion.

Scheele and Priestley.—In contrast to the deliberative work of Black and Cavendish, the rapid series of experiments carried out by Karl Wilhelm Scheele in Sweden and by Priestley in England were remarkable for the brilliant observational powers brought into play and for the many discoveries that flowed from them.

Scheele found that various substances—especially bodies like sulphur and phosphorus—diminished the volume of air in which they were burnt; and the residual gas he found, against his expectation, to be lighter than ordinary air, and this lighter portion was no longer able to support combustion. The portion of the air concerned in the burning—his "fire-air" had disappeared. He burnt a jet of hydrogen in a measured volume of air over water, noticed how the flame died out, and then how the water rose in the vessel. Finding no evidence of any change in the water, he concluded that the missing air being neither condensed in the residual "foul air," nor dissolved in the water, must have escaped through the glass. The phlogiston (hydrogen) must have combined with the fire-air to form "caloric," and this had passed through the glass walls. He set himself to reverse the process. If caloric could be passed into a substance avid for phlogiston, the caloric might be broken up, the phlogiston retained and the fire-air liberated. Several bodies, he thought, would strongly attract phlogiston—such as nitric acid, pyrolusite (which he had himself investigated) and the red calx of mercury. When heat was applied to nitric acid, red fumes were evolved, and when these were absorbed by lime, a colourless gas remained, which supported combustion brilliantly. He had liberated the sought-for "fire-air." Similarly the calx of mercury, when heated in a vessel over a charcoal furnace, combined with the phlogiston of the caloric to form metallic quicksilver and the pure fire-air was set free. He added his fire-air to the residual "foul-air" in due proportion and found the mixture behaved as common air.

Scheele interpreted all his results in terms of the phlogistic theory. Thus when he first isolated chlorine by heating pyrolusite with hydrochloric acid, he imagined the pyrolusite had absorbed phlogiston from the acid, and he named the new gas "dephlogisticated marine acid." We owe to Scheele hydrofluoric, hydrocyanic, arsenic, tungstic and molybdic acids, and a long list of organic substances including glycerine and milk sugar, with oxalic, tartaric, citric, malic and other acids.

Scheele's discovery of fire-air, probably made in 1773, was not published until 1777. Meanwhile, on Aug. 1, 1774, Priestley had concentrated the sun's rays through his new burning-glass on the red calx of mercury contained in a glass vessel over mercury, and found an air was expelled from it very readily. This air he found was not soluble in water, "but," he writes, "what surprised me more than I can well express was that a candle burned in this air with a remarkably vigorous flame." Now Priestley had previously shown that the respiration of animals acted like burning bodies on common air, diminishing its volume and rendering it noxious. This new air, he found, differed from common air not only in supporting combustion more vividly but in prolonging the life of animals breathing it. His explanation was that while common air is always partially saturated with phlogiston and cannot make room for much more, the new air is uncontaminated and phlogiston can rapidly escape into it—as into a vacuum. He named the new gas therefore "dephlogisticated air," and the residual inert nitrogen he named "phlogisticated air."

Priestley was the first to prepare and describe the gases nitric oxide and nitrous oxide, which he collected over water, and the gaseous hydrogen chloride, ammonia, sulphur dioxide and silicon fluoride, which he collected over mercury.

Lavoisier.—The outstanding features of Lavoisier's work were the use of the balance and the clearness with which he interpreted quantitative results, a clearness founded on his conviction (partly gained from Black) that no ponderable matter disappears in any chemical change. He heated water in a sealed glass vessel for many days, and found the weight of the whole unaltered. On pouring out the water he found the glass had lost in weight, but on evaporating the water he recovered the lost weight in the alkaline silicates which had been dissolved from the glass.

In 1772 Lavoisier began his researches on combustion. When sulphur and phosphorus were burnt in air a portion of the air was fixed. The same thing was observed when lead and tin were calcined in air sealed in glass vessels: there was no change in weight until the vessels were opened and the air rushed in. In 1775, after hearing from Priestley of his "dephlogisticated air," and after repeating the experiment with the red calx of mercury, Lavoisier grasped the true explanation of combustion. The "pure" or "vital" air was combined with the metal in the calx, and this

pure air formed that portion of common air which produced calcination by combining with the metal. Then followed the quantitative demonstration that mercury heated in common air slowly combined with the "vital" part and formed the red powder—*mercurius calcinatus:* from this powder, more strongly heated, the vital air was recovered, and this mixed with the inert "azote" (left in the first experiment) reformed exactly the original quantity of common air.

Finding that nonmetallic elements such as sulphur and phosphorus gave acids when combined with his vital air, and having shown that carbon yielded Black's fixed air (Bergman's aereal acid), Lavoisier adopted the name oxygen (acid-maker) for the substance which, combined with caloric, formed "oxygen gas." While the nonmetallic elements gave acids by their combination with oxygen, the metals gave calces—the oxides of the metals; and the union of the two kinds of oxides gave the various metallic salts. But, the phlogistonists could still object, this did not explain the formation of inflammable air when metals were dissolved in acids. Just the same salt was formed by the union of a calx with an acid as by the solution of the metal in the acid; but in the latter case the metal gave up its phlogiston as inflammable air. Moreover, unless the calx were originally present in the metal, there was no obvious source from which the metal could obtain the oxygen necessary to form the calx. It was a difficulty only to be solved by Cavendish's proof that water was formed when inflammable air was burnt. Informed of Cavendish's work, Lavoisier and Laplace repeated the experiment and by their correct interpretation supplied the missing data. In the solution of a metal by an acid, the oxygen of the water combines with the metal, liberating the inflammable air—now named hydrogen—while the two oxides (the calx and the acid) combine to form the salt. This was the deathblow to the phlogistic theory.

Founded on Lavoisier's oxygen theory, a new nomenclature was evolved, and this has largely survived to our day. It was perhaps natural that the new school should consider oxygen to be an essential constituent of all acids, and that the acid from sea salt, muriatic acid, should be regarded as formed by the union of an oxide of an unknown nonmetallic element murion with water, and that chlorine—Scheele's "dephlogisticated marine acid"—should be an oxygenated compound of this, or "oxy-muriatic acid."

THE ATOMIC THEORY

Before the publication of John Dalton's atomic theory, and indeed even before the formal enunciation of the law of the conservation of mass by Lavoisier, there was some recognition of the principle of equivalency in chemical combination. This can be traced back to Black's work on fixed air and magnesia alba about 1755. The subject of equivalency and the law of reciprocal proportions are usually identified with the name of J. B. Richter (1792), but experimental work on the neutralization of acids by bases, in which the principle of equivalency was recognized, were carried out at an earlier date by Cavendish. Clerk Maxwell, in his notes on Cavendish's electrical researches adverting to a particularly remarkable set of experiments carried out in 1777, pointed out that Cavendish must have carried out some equivalent weight determinations before this date but he did not publish them. The actual values were very similar to modern figures. On the subject of the determinations Maxwell remarked that "Cavendish was accustomed to compare the quantity of fixed air from different carbonates with that from 1,000 grains of marble. Now the modern equivalent weight of marble is 100, so that if Cavendish took 100 pennyweights as the equivalent weight of marble, the equivalents of other substances would be as he has given them."

In 1803 Claude Louis Berthollet published an important work entitled *Essai de statique chimique* which exercised considerable influence upon the progress of chemistry in more than one direction. Broadly speaking the *Essai* was an attempt to bring ideas regarding the course of chemical change and the composition of substances resulting therefrom under a few general principles. In this respect Berthollet made a marked advance upon the ideas regarding chemical affinity which were expressed during the 18th century by men such as T. O. Bergman and C. F. Wenzel. Berthollet was able to see the fallacies of Bergman's tables of affinity, and he pointed out that the course of chemical change was capable of modification by change in the relative quantities of the reacting substances. A most important feature of Berthollet's ideas was the recognition of a state of chemical equilibrium, and that the establishment of equilibrium was determined not only by the affinities of the reacting substances but upon their amounts. Berthollet regarded chemical affinity as akin to gravitational attraction, but at the same time he realized that it was a much more complex phenomenon. In spite of the limitations of his ideas, Berthollet must be regarded as a pioneer in the development of the law of mass action, a principle which was first clearly formulated by C. M. Guldberg and P. Waage in 1867.

Berthollet's brilliant ideas regarding the reversibility of chemical reactions unfortunately led him into serious errors regarding the constancy of composition of substances. The quantitative work of Black, Cavendish, and Lavoisier had all gone to show that compounds, however prepared, contain their constituents in definite proportions. Berthollet maintained a contrary opinion, and he asserted that the composition of compounds was determined by the conditions under which they are produced. This erroneous doctrine gave rise to a celebrated controversy with J. L. Proust, who was able to show as the result of his analytical work that the composition of compounds is constant and definite.

The controversy between Berthollet and Proust was followed in 1808 by the publication of Dalton's *New System of Chemical Philosophy*, vol. i, part i. In this work Dalton put forward his atomic theory. The origin of this theory has been the subject of some discussion. Among Dalton's contemporaries, including his biographer Henry, it was widely believed that Dalton derived his theory as the result of his experimental work on combination in definite and in multiple proportions. It seems certain, however, that Dalton had ideas regarding an atomic constitution of matter some years before the publication of the *New System*, and a careful examination of Dalton's notebooks by H. E. Roscoe and A. Harden led in 1896 to the conclusions expressed in their *New View of the Origin of Dalton's Atomic Theory* that the theory had been arrived at by deductive reasoning and not inductively as a result of a study of the laws of constant and multiple proportions. Dalton was known to be keenly interested in Isaac Newton's works, and it would seem that his study of the *Principia* and even more of the *Opticks* was the real source of his own atomic conceptions.

The study of quantitative relations between the volumes of gases taking part in chemical reactions dates back to the time of Cavendish, and in 1808 J. L. Gay-Lussac enunciated a general law, known by his name, which gave formal expression to such relations. Dalton, too, had done much experimental work in this direction, and he attempted, but without success, to discuss the results in terms of his atomic theory. In passing, it may be noted that while Dalton was a pioneer in scientific thought, as an experimentalist he was far from exact. Gay-Lussac's law which states that when gases combine together they do so in simple proportions by volume and the volume of the product, if gaseous, bears a simple relation to the volumes of the reacting gases, was a purely experimental generalization and was not accompanied with any theoretical discussion. Dalton ventured the suggestion that under identical conditions of temperature and pressure equal volumes of gases contain the same number of atoms, but he very soon found that this would lead to error. In 1811 A. Avogadro got over the difficulty by drawing a distinction between the ultimate particle of an element which can take part in a chemical change, the atom, and the ultimate particle of an element or compound which can exist by itself, this latter he termed a molecule. By replacing the word atom by the word molecule in Dalton's suggestion, the well-known hypothesis of Avogadro was formulated, viz., that under identical physical conditions equal volumes of gases contain the same number of molecules. This hypothesis, originally framed to explain Gay-Lussac's law, became the very corner-stone of modern chemistry. Every advance after that time in one way or another provided fresh evidence of its truth, so

much so that it became customary to refer to Avogadro's *law*.

Although formulated three years after Gay-Lussac's law it took nearly half a century for Avogadro's ideas to secure general recognition among chemists. Dalton was antagonistic to the theorem after having seen the failure of his own attempt to discuss chemical combination in terms of gaseous volumes—indeed he challenged the accuracy of Gay-Lussac's law, relying upon the results of his own less accurate experiments. The state of chemistry for some 50 years after the publication of Avogadro's hypothesis was one of much confusion, no fewer than four "systems" of chemistry having been introduced between 1826 and 1858 associated with the names of J. J. Berzelius, L. Gmelin, C. F. Gerhardt, and S. Cannizzaro. Two important principles were introduced in 1819 which exerted much influence in fixing atomic weights and in the establishment of formulas, namely the law of Dulong and Petit and Mitscherlich's law of isomorphism. P. L. Dulong and A. T. Petit pointed out that the product of the specific heat of a solid element and its atomic weight was approximately constant, and E. E. Mitscherlich showed a connection between identity of crystalline form and of chemical composition. In 1826 J. B. A. Dumas devised a useful method for determining vapour densities by which molecular weights of substances could be determined in the vaporous condition. Berzelius carried out some good atomic weight determinations, and he made some use of the above-mentioned principles in establishing the formulas of inorganic compounds. Although some of his formulas were identical with those which are now in general use, others were not, and it is certain that in attempting to make use of volume relationships he failed to do so in a consistent and logical manner—in short his failure was due to neglect of Avogadro's principle. Gmelin's system was regarded by some as an improvement on that of Berzelius, but both were essentially founded upon gravimetric experiments; indeed Gmelin's atomic weights were what would now be termed equivalent weights. A much closer approach to the establishment of a satisfactory system of chemistry was realized by Gerhardt and strongly supported by A. Laurent. Both Gerhardt and Laurent stressed the molecule, not the atom, as the fundamental unit in chemistry. Gerhardt's system, in which due account was taken of Avogadro's rule, was largely successful with organic compounds, but with inorganic compounds it was somewhat of a failure. The final step, which resulted in the establishment of a completely logical system of chemistry with consistent formulas and atomic weights, was taken by Cannizzaro in 1858. He insisted upon the necessity of accepting Avogadro's hypothesis as universally applicable, and was able to explain the cause of certain apparent exceptions, resulting in the deduction of impossible formulas, as a consequence of thermal dissociation. Cannizzaro was able to deduce correct values for atomic weights by showing that, once the molecular weight of a compound had been established by a determination of its vapour density, the value of the atomic weight of some particular element in the compound must be fixed within a certain limit. By choosing a sufficient number of compounds of that element, he pointed out that there was reasonable probability of obtaining a compound containing only one atom of the element in the molecule of the compound, and thus of correlating the value of its equivalent weight with the atomic weight. Cannizzaro's system rapidly received general acceptance, but it is interesting to note that certain French chemists, particularly Sainte-Claire Deville, who had carried out much valuable experimental work on thermal dissociation, were unable to accept the explanation of the so-called abnormal vapour densities of substances like ammonium chloride and phosphorus pentachloride as being due to thermal dissociation. In short, they regarded such compounds as being exceptions to Avogadro's theorem. It was recognized by Cannizzaro, by H. Kopp, and by F. A. Kekulé that there was no question of any such exception, but that when values for the molecular weight of a compound in the vaporous state were obtained which were inconsistent with its formula, such results were due to an increase in the number of molecules in a given volume brought about by partial or complete thermal dissociation.

The experimental demonstration of this important principle was largely due to C. A. Wurtz.

The development of chemical theory between Dalton's time and that of Cannizzaro was much influenced by studies on electrolysis and on the reactions of organic compounds. In 1819 Berzelius put forward his dualistic theory of chemical combination, according to which salts were regarded as the products of the union of an electropositive (basic) oxide with an electronegative (acidic) oxide. With oxyacids and their salts this theory enjoyed some success. Its subsequent downfall was largely brought about by H. Davy's discovery of the elementary nature of chlorine, and also by Dumas' discovery that acetic acid could be converted into trichloracetic acid without causing a profound change in the nature of the product. Once it had been discovered that elements of opposite electrochemical character could replace each other in a compound, Dumas was able in 1839 to formulate his theory of types—an idea altogether at variance with the electrochemical ideas of Berzelius. Shortly before this time J. von Liebig and F. Wöhler had published their investigation on the radical of benzoic acid, and in 1841 R. W. Bunsen had begun his investigations on the cacodyl compounds. In these researches it had become recognized that a group of elements could take part in a number of reactions without the group thereby losing its individuality. In 1833 T. Graham showed that phosphoric and arsenic acids were capable of giving rise to more than one type of salt, and shortly afterward extended his work to organic acids and thus developed a theory of polybasic acids. Of other investigations which influenced the development of chemical theory, particular mention should be made of A. W. Williamson's experiments on etherification between 1850 and 1856. These and other departments of study all served, in one way or another, to elaborate the various theories of structure, known as the type and residue theories, associated particularly with the names of Gerhardt and Kekulé. (*See* historical introduction to CHEMISTRY: *Organic*.)

The various type theories gradually developed into a general theory of valency, largely as the result of the work of E. Frankland on organo-metallic compounds about 1852, and of H. Kolbe's experiments on the electrolysis of the salts of organic acids which were begun about 1845. Important theoretical developments were made by A. S. Couper in 1858 and especially by Kekulé from 1858 onward. Frankland and Kekulé were agreed in regarding valency as a property of an atom of an element expressing its capacity for saturation with hydrogen atoms, but they differed on the question of the variable or constant nature of valency. Kekulé saw that success in the development of organic chemistry would rest on the assumption of the constant quadrivalency of carbon, and accordingly he regarded other elements as having invariable valencies. Frankland preferred to regard an element such as phosphorus as being tervalent in the trichloride and quinquevalent in the pentachloride, and generally that valency was variable. Kekulé regarded phosphorus as definitely tervalent in all compounds. He regarded a substance such as phosphorus pentachloride as a "molecular" compound of the trichloride and chlorine and wrote the formula as PCl_3,Cl_2. Such formulas had much to recommend them; *e.g.*, the readiness with which the substances can undergo thermal dissociation, but it was soon found impossible to maintain a distinction between "atomic" and "molecular" compounds, so Frankland's view regarding the variable nature of valency received general acceptance.

Classification of the Elements.—In the early years of the 19th century several chemists; *e.g.*, J. W. Dobereiner and Dumas, attempted to establish relations between the values of the atomic weights of elements and their properties. Thus in several instances it was not difficult to show that there was a gradation of properties when three elements of similar nature and increasing atomic weight were considered together. Thus bromine which is intermediate in properties between chlorine and iodine has an atomic weight which is roughly the arithmetic mean of these two elements. Important advances in correlating the properties of elements with their atomic weights were made independently by A. E. B. de Chancourtois in 1862, by J. A. R. Newlands in 1866 who put forward his law of octaves, and by D. I. Mendeléyev in 1869 who elaborated a periodic system of classification. The ideas

of de Chancourtois and of Newlands, which were fundamentally identical with those of Mendeléyev received almost no recognition, but Mendeléyev not only pointed out that when the elements were arranged in the order of ascending atomic weights similar elements occur at intervals of eight (Newlands' law of octaves) but was able to predict the existence of hitherto undiscovered elements and to correct the values of several erroneous atomic weights. Almost simultaneously with Mendeléyev, Lothar Meyer established the same principle, namely that the properties of the elements and of their compounds are a periodic function of their atomic weights, and he expressed his ideas graphically by plotting the atomic weights as abscissas against the atomic volumes of the elements as ordinates. Lothar Meyer, however, adopted a more restrained attitude to the whole subject, and he was opposed to altering the atomic weights of such elements which did not fit into the system.

Among the important theoretical aspects of the periodic classification, Mendeléyev drew attention to the valencies of the elements as measured by their combining capacities for hydrogen and for oxygen respectively. He pointed out that in a number of instances the sum of the "hydrogen" and of the "oxygen" valencies was equal to eight. Some 30 years later the same principle, expressed in electrochemical language, was formulated by R. Abegg, who regarded the elements as endowed with two different kinds of valency, namely a normal (electropositive) valency, and what he termed a contravalency of electronegative character. Thus phosphorus would have a normal valency of three in phosphine, PH_3, and a contravalency of five in the pentachloride, PCl_5. Abegg's theory amounted to a revival of Berzelius' dualistic theory welded on to the periodic system of classification. It attracted some attention at the time, but was less fruitful than an earlier conception of Werner's (*see* below).

Apart from a few elements which were discovered soon after Mendeléyev's formulation of the periodic law and were readily fitted into the table, a new situation arose after 1894 as the result of the discovery of the inert element argon by Lord Rayleigh and W. Ramsay, followed by that of helium in 1898, and of neon, krypton and xenon by Ramsay and M. W. Travers between 1898 and 1901, and the position of these elements in the periodic table required to be settled. Mendeléyev had previously drawn attention to the periodicity of electrochemical character shown by the elements, and accordingly Ramsay was able to show that the inert gases could be placed in a new group between the strongly electronegative halogens and the powerfully electropositive alkali metals, this position being in agreement with their atomic weights. The position to be assigned to the rare earths in the periodic table was a more difficult one, and remained unsettled until after H. G. J. Moseley's work on atomic numbers in 1913. This important generalization, according to which the atomic number as distinct from the atomic weight is regarded as the fundamental property of an element, gave a theoretical foundation for the periodic law and has been the means of removing some of the irregularities inherent in the original system; *e.g.*, inversion in the order of tellurium and iodine when considered with regard to atomic weights.

Until the closing years of the 19th century the atom had been regarded as the indivisible unit of elementary matter, although speculations regarding the possibility of the elements being composed of some fundamental substance had been advanced at various times. In 1815 W. Prout ventured the suggestion that the atomic weights were all integral numbers, being multiples of that of hydrogen. Accurate atomic weight research showed that such an idea was fundamentally erroneous, and accordingly Prout's hypothesis was abandoned, but it nevertheless continued to exercise a certain amount of interest for some chemists as it was well recognized that a large majority of the atomic weights tended to approach toward whole numbers. The correct explanation of the true significance of atomic weights, and generally of the elements as regards their places in the periodic table, was eventually given chiefly as a result of studies on radioactive phenomena and of analysis by rays of positive electricity during the early years of the 20th century. These investigations gave rise to a greatly extended conception of the nature of the elements (*see* ATOM; ATOMIC NUMBER; ISOTOPES, etc.).

Modern Views on the Elements and the Periodic Table.—Investigations of radioactive phenomena, particularly those of E. Rutherford and F. Soddy, had shown that certain elements of high atomic weight such as uranium, thorium, and radium, undergo spontaneous transformation into other products, and they explained these phenomena in terms of a theory of *atomic disintegration* in 1903. In the following year Ramsay and Soddy were able to demonstrate the formation of helium from radium by radioactive change, and in 1908 Rutherford and H. Geiger gave an experimental proof of the identity of the α-particle and the helium atom. As the atomic weight of helium is 4, it follows that whenever a radioactive atom suffers a loss of an α-particle its atomic weight must descend by 4 units. Gradually it was recognized that the final product of a succession of such changes would be lead, but if the origin of the lead was uranium its atomic weight would be 206, whereas if the source of the lead was thorium its atomic weight would be 208. The correctness of this reasoning was shown by the independent work of Soddy, T. W. Richards, K. Fajans and others since 1913 on the atomic weight of lead extracted from uranium and thorium minerals. The value of 207.1 for the atomic weight of ordinary lead is the mean value of the isotopes (a term attributable to Soddy) of which it consists. In 1911 J. J. Thomson introduced his method of analysis with positive rays and, a few years later, Aston introduced some improvements into the experimental method, particularly what he termed the mass spectrograph. With the aid of this apparatus F. W. Aston was able to show that a majority of the elements consist of isotopes, the atomic weights of which are whole numbers, and where an element has an atomic weight with a clearly defined figure after the decimal point, this is due to the value being an average one, just as in the case of the isotopes of lead. Thus in 1920 Aston showed that chlorine consists mainly of two isotopes having atomic masses of 35 and 37 mixed in such proportions as to agree with the atomic weight of 35.46 of this gas.

Much progress regarding the nature of the elements resulted from studies on X-rays, particularly from the work of the Braggs on the diffraction of these rays by crystals begun in 1912 and of the introduction of X-ray spectroscopy by Moseley in the following year. It was as a direct result of this latter work that atomic numbers were placed upon a sound experimental foundation. When the elements are arranged in the periodic table according to their atomic numbers, not only were the irregularities inherent in the older table removed, but, as the elements were now definitely "numbered," the difficult problem of the rare earths was solved, and some new elements were discovered by applying the methods of X-ray spectroscopy as an adjunct to the older methods of examining products from minerals. The numbering of the elements soon directed attention to some which, though undiscovered, were none the less believed to exist, namely those of atomic numbers 43, 61, 72, 75, 87 and 91. Particular interest is attached to the discovery of elements 72, 75, and 91. Element 91 was discovered in 1918 by O. Hahn and L. Meitner, and independently by Soddy and J. A. Cranston, by the methods of radioactivity, and is now known as protoactinium and is similar to tantalum. In 1923 G. Hevesy and D. Coster discovered element 72, which they termed hafnium and showed it to resemble zirconium. The discovery of element 75 was made in 1925 by W. and I. Noddack who recognized its relation to manganese.

Although modern atomic science dates from the beginning of the 20th century, and the views of chemists regarding the nature of the elements have thereby been greatly modified, it should be noted that many phenomena, formerly regarded from a purely empirical standpoint, have received much more enlightened explanations in consequence of our knowledge of atomic structure. The recognition of electrons as universal constituents of atoms was admitted toward the end of the 19th century. In 1904, J. J. Thomson regarded atoms as consisting of electrons embedded in a sphere of positive electricity, and he showed that considerations of this kind could furnish some explanation of the periodic system of the elements. Shortly afterward he showed that valency could

be explained on an electrochemical basis. This idea was further elaborated by Kossel and independently by G. N. Lewis in 1916, the views of the former being chiefly concerned with ionizable substances, and those of the latter with nonelectrolytes. In developing his views, W. Kossel made some use of Abegg's conceptions of normal and contravalency and of the position of the inert gases in the periodic table, but without adopting any particular type of atomic model. Lewis, however, made use of a cubical atomic model, the electrons being situated at the corners—an arrangement which although theoretically unsound was nevertheless successful in giving expression in electronic language to the single, double and triple bonds of classical chemistry. In 1923 further fundamental contributions to an electronic theory of valency were made independently by T. M. Lowry and by N. V. Sidgwick. Sidgwick developed his views around the model atom of Rutherford and N. Bohr, and one of his outstanding achievements was the placing of A. Werner's theory of valency on a satisfactory electronic basis. Werner first put forward ideas in 1891, in which he drew a distinction between what he termed principal or primary valencies and secondary or auxiliary valencies, the former being concerned primarily with electrolytes, the latter more particularly with the attachment of substances such as water or ammonia to inorganic compounds. Although Werner developed his ideas in a purely empirical manner, and without entering into questions regarding the nature of valency, he made a definite advance upon the earlier ideas of Frankland and Kekulé, and in particular he provided the means of discussing isomerism among inorganic compounds. Kossel and Lewis had shown the possibility of explaining the two fundamental types of valency, namely electrovalency and covalency, on the basis of a transference and of a sharing of electrons respectively. Lowry and Sidgwick recognized a third type of valency, generally known as the co-ordinate link, in which donation of electrons is directive from some particular atom in a molecule to others, as distinct from the reciprocal sharing of electrons between atoms as in simple covalency. For further developments of electronic theories of valency *see* VALENCE.

About 1913 J. J. Thomson's conception of atoms, consisting of a uniform sphere of positive electricity with the electrons embedded within it, was abandoned in favour of an idea of Rutherford in which the mass of the atom, that is, the positive electricity, was concentrated into an extremely small central portion known as the nucleus, the electrons being disposed in orbits around it at considerable distances in comparison with the dimensions of the nucleus. Rutherford's conception was extended by Bohr, and was of immense importance in the development of atomic science. According to the conceptions inherent in the Rutherford-Bohr atom, it is the peripheral electrons which determine the ordinary chemical properties and reactions of an element, the nucleus being inert. In radioactive change, however, the nucleus is directly concerned. Until 1919 radioactivity had been regarded as fundamentally a property of elements of high atomic weight; *e.g.*, uranium, thorium and radium, but in that year Rutherford realized that it might be possible to attack the nuclei of elements of light atomic mass and thus effect artificial radioactive change. In this he was successful. He attacked nitrogen atoms with swiftly moving α-particles and obtained evidence of the liberation of hydrogen. This successful result was soon followed by experiments on the artificial disintegration of other elements, such as beryllium, boron, aluminium and phosphorus, and a considerable number of investigators have entered this field of research. After 1932 it became recognized, largely as the result of the work of J. Chadwick, of Irène Curie and F. Joliot, and of C. C. Lauritsen and H. R. Crane, that when the nuclei of elements of light atomic mass are bombarded with α-particles the attack may take place in two entirely different ways. It may result in the formation of a new and stable atomic nucleus with the emission of a proton, namely a particle of the mass of a hydrogen atom and carrying a positive charge. Alternatively, the product may consist in the formation of an unstable (radioactive) atomic nucleus accompanied with the emission of what Chadwick termed a neutron, namely an uncharged particle of mass similar to that of a proton. When the attack takes place in the latter way, the newly formed radioactive element undergoes atomic disintegration, with the production of a new and stable atomic nucleus and the emission of a strongly penetrating radiation derived from a positively charged electron, usually termed a positron.

It will thus be evident that the recognition of atoms as built up of protons and electrons—for many years a valuable basis for the study of fundamental questions in physics and chemistry—has become more complex. Theories concerning atomic structure must now take account of the discovery of the neutron and the positron. It is possible to regard the neutron and the proton on the one hand, and the positron and the electron on the other as modifications of two fundamental elementary particles—a modern development of the old problem regarding the nature of positive and negative electricity.

INORGANIC CHEMISTRY

Inorganic chemistry, which is concerned with the study of the elements and compounds other than those of carbon, was developed primarily through the investigations of minerals, whereas organic chemistry (*see* below) resulted from the study of substances of plant or animal origin. Although it was recognized that the two classes of substances were amenable to the same general chemical laws, it was supposed that a fundamental difference existed between the mineral (inorganic) substances and those which were the products of life processes (organic). However, during the middle of the 19th century it was found that organic substances could be prepared from their elements or from inorganic compounds, a fact which gave great impetus to the study of organic substances in the latter half of the century. Nevertheless, it is usual and convenient to divide chemical substances arbitrarily into the two classes, but to include the oxides of carbon, the carbonates, metallic carbonyls and certain other simple compounds of carbon as well as water and ammonia in the domain of inorganic substances.

Early Discoveries.—The earliest discoveries in inorganic chemistry were made in the metallurgical and medical arts and in the domestic economy of the ancients. Gold, silver, copper, tin, iron and lead, some of the simpler alloys, metallic salts and mineral products, and the rudiments of metallurgical, glass-making, enamelling, painting, dyeing, alchemical and medical arts were known to the ancient Chaldeans, Hindus, Chinese, Egyptians and Greeks, many centuries before the Christian era. By about the middle of the 17th century, the alchemists were acquainted with most of the common metals, their alloys and salts, a few acids, alkalis, medicinal minerals, and nonmetallic elements. In 1733 G. Brandt of Sweden isolated cobalt, and in 1750 A. F. Cronstedt prepared metallic nickel. These discoveries were followed by Henry Cavendish's recognition of elementary hydrogen in 1766, the isolation of nitrogen by Daniel Rutherford in 1772, manganese by J. G. Gahn in 1774, oxygen by Joseph Priestley and chlorine by K. Scheele in 1774, and molybdenum by P. J. Helm in 1782. Cavendish in 1784 made the far-reaching discovery that water is composed of two volumes of hydrogen to one of oxygen, and in the following year he succeeded in synthesizing nitric acid by passing electric sparks through moist air. His further discovery, that a minute residue of the air would not combine with oxygen, was

ignored for more than a century, until Lord Rayleigh and Sir William Ramsay in 1895 proved that the inert residue consists of a mixture of the noble gases, argon, krypton, neon and xenon.

Other elements discovered during the 18th century include uranium, zirconium, titanium, wolfram (tungsten), platinum, beryllium, chromium, tellurium and a number of the rare earth metals, all of which are elsewhere fully discussed. The quantitative studies of chemical reactions by A. Lavoisier and others during the last part of the century led to a clarification of the nature of combustion and the abandonment of the doctrine of phlogiston. Laws governing chemical combinations were formulated and the atomic theory announced by J. Dalton in 1803 was generally accepted (see *History of Chemistry* above).

At the beginning of the 19th century the discovery of methods for the generation of the electric current gave to chemistry a most effective means for the separation of compounds into their elements. By the use of electrolysis, Sir Humphrey Davy in 1808 decomposed the supposed elements soda and potash and isolated the metals sodium and potassium. Shortly thereafter he obtained magnesium, calcium, strontium and barium from their respective oxides. With the new tools and techniques, chemistry and other sciences underwent a rapid growth. In addition to the striking developments in analytical and preparative chemistry there were numerous advances in the theoretical sciences; physical laws and principles were found to be applicable to chemical phenomena. Among all of the advances in theoretical, descriptive and industrial chemistry which took place in the 19th century, the two events which perhaps have contributed the most to inorganic chemistry are the formulation of the periodic law and the discovery of the electron.

The periodic law (*q.v.*) and the periodic classification of the elements, announced by D. Mendeléyev (1869), is the great fundamental generalization of chemistry, stimulating to research and serving as a framework for the organization of the vast amount of factual material which had been gathered and which had previously been organized only to a limited degree.

The profound and revolutionary effect of the discovery of the electron (1897), and the subsequent chain of related discoveries and theories, upon the character and scope of inorganic chemistry is treated after an introduction to chemical formulas and a few of the basic concepts.

Symbols and Formulas.—The chemical symbol for an atom of an element is either the capital letter of its English or Latin name, as C for carbon and K for potassium (Latin, *kalium*), or the capital letter followed by a small letter as Co for cobalt and Cr for chromium. A symbol is not merely an abbreviation but has a quantitative significance. It may represent one atom of the element whose weight relative to an arbitrarily selected unit is a number known as the atomic weight; or, alternatively it may represent a gram atomic weight or a gram atom which consists of 6.023×10^{23} atoms of the element and whose weight expressed in grams is numerically equal to the atomic weight. For example, the symbol C may stand for one atom of carbon whose relative weight is the pure number 12.010; or if more convenient it may stand for 12.010 grams of carbon which contains 6.023×10^{23} atoms (*see* ATOM).

A chemical formula represents a molecule of a substance which may be either an element or a compound. Since the formula is composed of symbols it shows qualitatively the constituent elements and quantitatively the number of atoms of each element in the molecule. Thus O_2, the formula for oxygen, indicates that the substance is an element and that a molecule of it consists of two atoms; He, the formula for helium, indicates that the molecule is monatomic and is identical with the atom; while Fe_2O_3 signifies that a molecule of ferric oxide consists of two atoms of iron and three atoms of oxygen and since it contains more than one element that the substance is a compound. Chemical formulas are established by experimental methods which involve a chemical analysis and the determination of the molecular weight of the substance. Empirical formulas are those which indicate the simplest ratio between the numbers of the component atoms while molecular formulas indicate further the actual number of atoms of each element in one compound molecule; *i.e.*, in the smallest portion of the compound that can exist as a separate entity. The empirical formula of hydrogen peroxide, for example, is HO but the molecular formula is H_2O_2. Empirical and molecular formulas of inorganic compounds are often identical. The establishment of an empirical formula requires only a chemical analysis of a compound and the atomic weight of the constituent elements, but that of a molecular formula requires, in addition, the molecular weight of the compound.

Once the molecular formula of a compound is determined it may in turn be used to calculate the molecular weight by addition of the atomic weights of all the atoms in the molecule. Hence the formula implies the molecular weight which may be a pure number expressing the relative weight of the molecule on the same arbitrary standard used for atomic weights or, alternatively it may represent a gram molecular weight or a mole which consists of 6.023×10^{23} molecules of the substance and whose weight in grams is numerically equal to the molecular weight (*see* MOLECULE, CHEMICAL).

Nomenclature.—By common agreement the formulas of inorganic compounds are usually written with the more electropositive element first and the electronegative element or radical last. The names of such compounds follow this order; for example, a compound of oxygen and fluorine is written OF_2 (oxygen fluoride) rather than F_2O. If the compound contains only two elements the name of the more electronegative element ends with the suffix *ide*. If the more electropositive element forms more than one compound with a given element, *i.e.*, has more than one valence (*q.v.*) the higher state of valence is given the suffix *ic* and for the lower *ous* is used, as in sodium chloride (NaCl), ferrous chloride ($FeCl_2$) and ferric chloride ($FeCl_3$) In some cases a prefix is used to inflect the electronegative element as in carbon monoxide (CO), carbon dioxide (CO_2) and chromium trioxide (CrO_3) as distinguished from chromic oxide (Cr_2O_3), sometimes called chromium sesquioxide, and a lower (divalent) valence state of chromium as chromous chloride ($CrCl_2$).

Inorganic compounds are generally classified in three groups: acids, bases, and salts. Conventional acids like sulphuric (H_2SO_4) and phosphoric (H_3PO_4) are prepared by a chemical combination of the acidic oxides (usually oxides of nonmetals) with water. Sulphur may be burned to sulphur dioxide (SO_2) which is further oxidized to sulphur trioxide (SO_3) which yields sulphuric acid (H_2SO_4). The phosphoric acid may be similarly prepared from phosphorus. These two acids which have high boiling points may in turn be used to prepare other acids from their salts as hydrochloric acid (HCl) by treatment of sodium chloride (NaCl) with sulphuric acid. The acids are named for the constituent element other than oxygen and hydrogen, usually a nonmetal. The names of the acids which contain no oxygen (binary acids) derived from the name of the nonmetal which is modified by the prefix *hydro* and the suffix *ic* as hydrochloric acid (HCl) and hydriodic acid (HI). The different oxygen acids of a nonmetal are distinguished from each other by the uses of the terminations *ic* and *ous* and the prefixes *per* and *hypo*. An acid in which the nonmetallic element is at a high state of oxidation (not necessarily highest) is designated by the termination *ic* with no prefix, and may be used as the starting point in the naming of the other acids of the nonmetal as for example the oxygen acids of chlorine: $HClO_4$, *per*chlor*ic* acid; $HClO_3$, chlor*ic* acid; $HClO_2$, chlor*ous* acid; HClO, *hypo*chlor*ous* acid.

The conventional bases of the water system are hydroxides of metals and are in some instances formed when the metal or basic oxide reacts with water; barium oxide, for example, (BaO) is converted to barium hydroxide [$Ba(OH)_2$]. Bases of this type are named for the metal with the uses of a suffix where necessary followed by the word hydroxide as cupr*ic* hydroxide [$Cu(OH)_2$] and cupr*ous* hydroxide (CuOH).

For purposes of nomenclature salts may be regarded as the products of reactions (neutralizations) of acids with bases. Although neutralization is one method of preparing salts, there are many more instances of naturally occurring salts being used to prepare acids or bases. Phosphoric acid is prepared from calcium

phosphate; sodium hydroxide from sodium chloride. Whatever may be the source of the salt there is a generic relationship between a salt on the one hand and the base which contains the same metal and the acid which contains the same nonmetal or negative ion on the other. Sodium sulphate may be regarded as a salt of sodium hydroxide and of sulphuric acid. This relationship is indicated by the name. Salts bear the first name of the base and an additional word which is derived from the name of the acid as follows: the suffix *ate* is used for salts derived from acids whose names end in *ic* and the prefix (if any) used in the name of the acid is retained; the suffix *ite* is used for salts derived from acids whose names end in *ous* and the prefix (if any) used in the name of the acid is retained. For example: Na_2SO_4, sodium sulph*ate;* $FeSO_3$, ferrous sulph*ite;* $Cu(ClO_4)_2$, cupric *per*chlor*ate;* KClO, potassium *hypo*chlor*ite.*

There are additional systems of nomenclature for special classes of inorganic compounds, such as complex salts and hydrogen compounds of boron and silicon which are included in the appropriate articles.

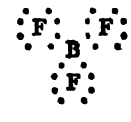
The Scope of Inorganic Chemistry.—By the early part of the 20th century a very large amount of factual material concerning the preparation and properties of the important elements and compounds was known and had been consolidated and organized in accordance with the periodic classification. The empirical and in some cases the molecular formulas of the compounds had been determined by chemical means. Molecules were regarded as entities composed of atoms about which little was known, bound together by valence forces the nature of which was totally unknown. Considerable progress had been made in the development of structural formulas of organic compounds, these showing the arrangement of the atoms in molecules. The valence bonds were represented by lines drawn between symbols, a practice which is still in common use (see *Organic Chemistry,* below).

The discovery of the electron, of X-rays and of radioactivity, all within the three year period following 1895, marked the beginning of a new era in all of the sciences. The investigations which followed these discoveries provided the means, both experimental and theoretical, for studying the chemical bond, the structure of molecules, and the structure of the solid state. The emphasis in the field of inorganic chemistry was consequently shifted from the analytical and the preparative to the structural.

The Chemical Bond.—The early theories and concepts of atomic structure were used in attempts to explain the forces which bind atoms together in molecules. In 1916 G. N. Lewis and W. Kossel independently published papers which contain the basis of the present ideas of chemical bonds or the electron theory of valence. Later N. V. Sidgwick applied the electronic theory to a wide variety of compounds including complex salts. Both Kossel and Lewis maintained that atoms of the inert gases have complete outer or valence shells of electrons, two in helium atoms and eight in the others. Kossel held that other atoms could acquire the stable inert gas configuration by the loss or gain of electrons. Thus the sodium atom which has an electron configuration of 2,8,1 could attain the electron structure of neon (2,8) by the loss of the outer electron, while chlorine with a configuration of 2,8,7 could by the gain of one electron attain the electron structure of argon (2,8,8), forming respectively the ions Na^+ and Cl^- which together constitute the compound sodium chloride. Valence bonds of this type are formed by electrostatic attraction between the ions which result from the transfer of electrons from one atom to another and are called ionic bonds. Lewis suggested that some atoms might achieve the inert gas structure and at the same time be held together by sharing the electron pair between them, usually each atom contributing one of the paired electrons. To illustrate this type of bond the electron dot system, in which the outer electrons are represented by dots, is used. The hydrogen atom with one electron is written H·, the chlorine atom with seven valence electrons $\cdot\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:$ and the hydrogen chloride molecule: $\mathrm{H}:\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:$

Similarly the structural formula of the chlorine molecule Cl_2 is: $:\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:\ddot{\underset{\cdot\cdot}{\mathrm{Cl}}}:$ The chemical bond so constituted is called the covalent bond. Both the ionic and covalent bonds represent extreme types. The chlorine molecule is symmetrical as the electron pair is not preferentially drawn to either atom, whereas, in the hydrogen chloride molecule the electron pair is drawn to the atom of higher electronegativity (Cl) giving the molecule an electrical assymetry or polarity. That is, one end of the molecule is negative, the other positive and consequently the molecule has a dipole moment. The degree of polarity in covalent molecules may vary from those like chlorine in which there is no polarity to a high degree of polarity approaching the ionic type.

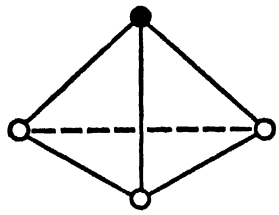
There are also double and triple covalent bonds which respectively involve the sharing of four and six electrons, ion-dipole bonds which result from the interaction of an ion with the oppositely charged end of a polar molecule, single electron bonds and triple electron bonds (*see* VALENCE).



Structural Chemistry.—The number of atoms of each element in a molecule and the molecular weight of the substance are determined by chemical or physical means. The determination of the structure, that is, the arrangement of the atoms in space, the interatomic distances and the bond angles involve an experimental study of how the substance interacts with energy. An aggregate of atoms which may be a molecule or an ion may absorb energy from a beam of light, X-ray or electrons and the modification of the beam observed; the group of atoms may acquire rotational or vibrational energy; or, it may react in a certain way in a magnetic or electrical field. The properties displayed by the group of atoms may be due to the nuclei or they may be due to the orbital electrons. The nuclei account for the mass and the scattering of other nuclei such as alpha-particles or deuterons and of fast moving electrons. The orbital electrons account for the scattering of X-rays, the absorption and emission of energy caused by movements of electrons from one quantum level to another and for magnetic properties caused by the movement of the electrons. Since the latter are charges in motion, they produce magnetic effects.

The data obtained from such studies are used to deduce the specific points of structure. Interatomic distances may be calculated from moments of inertia of atomic groups (the problem is difficult for more complex groups of atoms), from the scattering of X-rays which show the variation in electron density and permit the location of the nuclei, and from the scattering of electrons which is caused by the nuclei and from which their relative positions may be deduced. Neutron scattering is especially effective for compounds of hydrogen which do not readily respond to X-ray or electron scattering.

Unit cell constants in a crystal are determined by X-ray methods; the shape of a molecule may be approximately determined from the unit cell constants and confirmed by measurements of the dipole moment.



The internal energy of a molecule is of three kinds: electronic energy, energy of vibration of the nuclei and rotational energy. The loss or gain of any of these energies may be registered by appropriate spectroscopic methods which yield information concerning moments of inertia, molecular symmetry, force constants and dissociation energies.

Certain generalizations have been made concerning the relationship of the electronic structures of atoms and molecules to molecular configuration. For example, the compound boron trifluoride (BF_3) in which one s and two p orbitals are used for binding (the valence shell of boron contains one s and two p electrons which may pair with the electrons of fluorine) gives rise to a trigonal planar structure:

Nitrogen trifluoride utilizes for binding the three p orbitals of nitrogen ($:\dot{\mathrm{N}}\cdot$) the pair consisting of s electrons, and such ar-

rangement gives rise to a trigonal pyrimadil (a triangular pyramid) structure with nitrogen at the apex:

In addition to the utilization of the above physical techniques and theories, inorganic chemistry employs quantum mechanics, statistical mechanics, thermodynamics and natural and artificial radioactivity in its studies of structure and chemical reactions at various temperatures (high temperature chemistry is of special interest).

Preparative Inorganic Chemistry.—There is still considerable preparative chemistry in process which is of value per se and which is also concerned with problems structure. The fields in which considerable work has been done and is being done are: complex salts, hydrides of the light elements, and transuranic elements, the rare earths, rare elements such as beryllium, gallium and germanium, and metallic structure, all of which are treated extensively elsewhere. ORGANIC CHEMISTRY

The term organic chemistry came into use at the beginning of the 19th century. In its early usage it reflected, not a departmentalization of the science of chemistry, but rather the disposition of the chemists of the time (doubtless an inheritance from the alchemists) to classify substances on the basis of their origins. The assignment of matter of all kinds to the animal, vegetable or mineral kingdoms was at that time fairly general. Organic chemistry, therefore, was a convenient, inclusive term to designate the chemistry of substances of plant and animal origin, which were thought to be more closely related to each other than to substances of mineral origin.

Coexistent with this scheme of classification was a general conviction which further coloured the term and lent it additional implications—namely, that organic compounds (unlike mineral compounds) were necessarily the products of vital, or organic, processes exclusively, and could not be synthesized artificially in the laboratory, *cf.*, Leopold Gmelin, *Lehrbuch der Chemie* (1815).

In retrospect Friedrich Wöhler's classical conversion of ammonium cyanate, $NH_4^+CNO^-$, into urea, H_2NCONH_2 (1828), is often cited as the historic event that demonstrated the possibility of the preparation of organic compounds from inorganic materials. Many chemists of that time, however, argued that urea is, in fact, one of the end products of animal metabolism, and is, therefore, a result of the degradative rather than of the synthetic processes of living organisms, whereas others objected that the ammonia and the lead cyanate from which Wöhler's ammonium cyanate had been derived had been prepared in part from organic materials. The significance of Adolph Wilhelm Hermann Kolbe's synthesis of acetic acid, CH_3CO_2H (1845), was similarly discounted. It remained for Marcellin Berthelot to administer the *coup de grâce* to the notion of a vital force as an essential to the synthesis of organic compounds through the systematic series of researches described in his famous *La chimie organique fondée sur la synthèse* (1860).

Organic chemistry is often briefly, though not quite precisely, defined as the chemistry of carbon compounds. By common consent such carbon compounds as the metallic and ammonium carbonates, cyanides, carbides, cyanates and thiocyanates are relegated to the domain of inorganic chemistry, while such compounds as carbonic acid, the oxides of carbon and carbon disulphide are regarded as the joint property of organic and inorganic chemists.

At first thought it might appear absurd that a single element and its compounds should constitute the basis for one of the major branches of chemical science. The apparent absurdity diminishes, however, when relative volumes of subject matter are considered, for the known compounds of carbon far outnumber the noncarbonaceous compounds of all the other elements combined. Although no day-to-day census is possible, the number of known organic compounds must now approach, if indeed it has not already exceeded, 1,000,000.

EARLY DEVELOPMENT OF ORGANIC CHEMISTRY

The establishment of chemistry as a science may be said to have been achieved through the formulation and experimental justification of the concepts of: (1) conservation of matter; (2) chemical elements; (3) atomicity of matter and atomic weights; (4) stable aggregates of atoms; *i.e.*, molecules, and of molecular weights; (5) valence. The necessary experimental adjuncts to this primary evolution were the development of methods and techniques for: (1) the purification and identification of elements and compounds; (2) qualitative and quantitative analysis of compounds; (3) the determination of atomic and molecular weights. A further essential to rapid development of the science was the adoption of the modern system of chemical notation; *i.e.*, of molecular formulas and chemical equations, popularized, if not invented, by Jöns Jacob Berzelius (1819).

For the development of organic chemistry as an important branch of the science there were two additional necessities: (1) the demonstration of the generality of chemical laws and theories (specifically, of their applicability to organic compounds and reactions); (2) the formulation of a structural theory and of a convenient notation for its exploitation.

Re-exploration of the many blind alleys that chemists entered and the detours that they traversed in their progress toward these objectives would now be of interest only to the chemical historian. Indeed, anything beyond the barest outline of a few of the theories, discoveries and achievements that have proved to have survival value would be inordinately space-consuming, and, doubtless, tedious to the average reader. No more than a limited survey is attempted in the following discussion.

Chemists early discovered that organic substances yield water (H_2O) and "fixed air" (carbon dioxide, CO_2) when burned in oxygen. Antoine Laurent Lavoisier (1743–94), who perhaps, did more than any other one man to place chemistry on a quantitative basis, had shown that carbon, hydrogen and oxygen are the components of "spirits of wine" (ethyl alcohol, C_2H_5OH), and that carbon and hydrogen are among the chief components of other organic substances. Lavoisier's quantitative results were imperfect, partly because of impurities in the substances investigated (his alcohol undoubtedly contained water), partly because of defects in his methods and partly in consequence of his incorrect values for the compositions of water and carbon dioxide.

The first reasonably accurate investigations of the elementary compositions of organic substances were those of Louis Jaques Thénard and Joseph Louis Gay-Lussac, described to the scientific world in 1811. Regarding substances of vegetable origin they drew the conclusions that: (1) if oxygen is present in greater proportion (with relation to hydrogen) than in water, the substance is always acidic; (2) if hydrogen is present in excess, the substance is oily, resinous or alcoholic-like; (3) if hydrogen and oxygen are present in the same proportions as in water, the substance is analogous to the sugars, gums, starches or to wood fibre. Quite properly they limited their conclusions to the substances investigated by them, and pointed out that the validity of these statements as generalizations could be established only by the study of a greater number of vegetable substances. Regarding the substances of animal origin examined, they contented themselves with the observation that hydrogen was present in excess of the

amount necessary to form water with the oxygen found, and that the excess was combined with nitrogen "in the form of ammonia"; *i.e.*, in the same proportions as in ammonia.

By that time Berzelius had perfected himself in the art of chemical analysis, devising many of his own methods. In the course of about ten years he established, almost singlehanded, the experimental basis of the laws of definite and multiple proportions which John Dalton (1766–1844) had deduced theoretically from his atomic theory. An idea of the Herculean labours he performed is to be derived from the fact that a summary of his analytical studies (1818) tabulated data for about 2,000 simple and compound substances.

In 1814 Berzelius extended his investigations to organic substances. He pointed out that, notwithstanding the apparent differences between inorganic and organic substances, existing knowledge of the elementary compositions of inorganic substances must be the only safe guide to a correct conception of the mode of combination of those substances produced under the influence of life processes. It was probably this point of view that motivated his approach to the investigation of organic substances by way of the alkaline salts of organic acids.

These studies led to the idea that many organic compounds are oxides, whose radicals are, however, compound, whereas those of inorganic oxides were generally thought to be simple; *i.e.*, elementary. The idea of a radical; *i.e.*, of a body, which although compound, plays the part of a simple body (atom) in its combinations with other bodies, was not original with Berzelius. Lavoisier may, perhaps, be credited with having crystallized the concept, and he published a list of acid radicals. In 1815 Gay-Lussac isolated cyanogen, which he believed to be the free radical (CN) of prussic acid (hydrogen cyanide, HCN), but which is now known to be the dimer $(CN)_2$, and Berzelius had called attention to the analogy between the ammonium radical (actually, ion, NH_4^+) and the alkali metals; *i.e.*, the alkali metal ions, but the concept did not immediately find general favour among chemists.

In the meantime Justus von Liebig developed for carbon and hydrogen (1831), and Jean Baptiste André Dumas for nitrogen (1833), the methods of quantitative estimation which form the basis of modern methods of organic analysis.

Eventually the radical theory came into its own with the appearance of the classical paper of Wöhler and Liebig on "the radical of benzoic acid" (1832), which, sharing the misconceptions of their time concerning atomic and molecular weights, they formulated as $14C + 10H + 2O$. (The modern version is C_7H_5O, or, more specifically, C_6H_5CO.) The benzoyl radical of Wöhler and Liebig was shown to be something more than a hypothetical concept like the organic radicals of Berzelius. These investigators had, so to speak, employed it as a building stone, taking it out of one compound and putting it into another almost at will. Impressive as this demonstration was in itself, it was generally regarded as more remarkable still that a ternary radical; *i.e.*, one composed of three elements, could be so manipulated.

Moreover, chemistry had been, from the time of Lavoisier, predominantly the chemistry of oxygen. Generally speaking, oxygen was regarded as the one element that confers distinctive properties upon its compounds; it was erroneously supposed to be an essential constituent of both acids and bases, giving rise to the former in combination with nonmetals, and to the latter in combination with metals. The chemical world was surprised and impressed to learn that oxygen might be a constituent of an organic radical in which it apparently played no more distinguished a role than did carbon and hydrogen.

According to Wöhler and Liebig, benzoic acid is benzoyl oxide (actually, hydroxide, $C_6H_5CO.OH$), oil of bitter almonds is benzoyl hydride (benzaldehyde, $C_6H_5CO.H$), the compound of benzoyl with chlorine is benzoyl chloride ($C_6H_5CO.Cl$), etc. Thus, the same oxygen-containing radical is a constituent of various substances which differ considerably from each other in their chemical properties.

As may be appreciated readily, this discovery received widespread and enthusiastic notice, and it constituted the stimulus for much laboratory research and even more blackboard chemistry. Shortly thereafter, Liebig published a memoir (1834), which, in historical perspective, is seen as the foundation of the general radical theory. A few years later (1837–43) Robert Wilhelm Eberhard von Bunsen carried out his famous series of researches on the cacodyl radical $[(CH_3)_2As]$.

The revival and elaboration of the radical theory also set in motion another train of chemical thought with which the names of Dumas, Auguste Laurent and Charles Frédéric Gerhardt are most closely associated. Wöhler and Liebig had pointed out that the place of hydrogen in oil of bitter almonds (benzaldehyde, $C_6H_5CO.H$), or of oxygen; *i.e.*, of hydroxyl, in benzoic acid ($C_6H_5CO.OH$), may be taken by chlorine, bromine, iodine or sulphur; *i.e.*, SH. All the resulting compounds have some chemical likeness to each other in that all react with water to form benzoic acid and an inorganic acid,

$$C_6H_5CO.X + H_2O \longrightarrow C_6H_5CO.OH + HX$$

Dumas found analogies to this persistence of chemical type throughout a series of compounds in the likenesses between chloral (CCl_3CHO) and acetaldehyde (CH_3CHO), and between trichloroacetic and acetic acids (CCl_3CO_2H and CH_3CO_2H, respectively); in a series of papers published in 1840, he developed his theory of chemical types.

According to Dumas, the reaction of a halogen, of oxygen or of various compound radicals with an organic compound containing hydrogen usually results in the elimination of one or more equivalents of hydrogen and the fixation of the same number of equivalents of halogen, or oxygen, or other reactant, as the case may be. This sort of reaction, he said, takes place, however, only in cases in which the chemical type is preserved; *i.e.*, in cases in which the original reactant and the product have the same fundamental chemical properties.

Dumas, at that time still an adherent to the electrodualistic theory of chemical combination, was careful to specify that when he used the word substitution he did so only in an empirical sense; he did not believe that an element like chlorine could actually take the place of, and play the part of, an element like hydrogen in an organic molecule.

Sir Humphry Davy had suggested in 1807 that the components of chemical compounds are held together by the force of electrical attraction. Berzelius, who had also performed electrochemical experiments with the aid of a voltaic pile, had adopted this idea, and had developed it into the doctrine that all atoms (and hence all radicals, which behave like atoms) are either positive or negative electrically. According to Berzelius only bodies of opposite electrical nature could combine. From his point of view, nothing could be more absurd than the idea that negative chlorine could replace positive hydrogen in a compound without essentially altering the nature of the compound.

Laurent, however, was no devotee of the dualistic theory, and he made it plain that when he used the word substitution in discussing reactions that change the composition of an organic compound without essentially altering its chemical type he intended the word to be taken in its most literal sense. Perhaps, as Dumas charged, after the weight of chemical evidence had forced him to alter his own opinions and join the camp of the antidualists, Laurent originally allowed his intuition to carry him beyond the point where he was completely supported by experimental fact. Be that as it may, Laurent had the courage of his convictions, and, in the main, he was justified by subsequent events.

To Gerhardt must be conceded the credit for effecting a synthesis of the radical and type theories, for making use of the principle of Amadeo Avogadro and André Marie Ampère to arrive at the simplest molecular formulas for organic compounds, and for being among the first to make systematic use of "rational" formulas. Gerhardt attempted to group all organic compounds under four types: hydrogen, hydrochloric acid, water and ammonia. Thus, ethyl alcohol (C_2H_5-O-H), ethyl ether ($C_2H_5-O-C_2H_5$), acetic acid (C_2H_3O-O-H) and acetic anhydride ($C_2H_3O-O-C_2H_3O$) were all regarded as belonging to the water ($H-O-H$) type. Similarly, ethyl hydride (ethane, C_2H_5-H), biethyl (normal butane, $C_2H_5-C_2H_5$), acetyl hydride

(acetaldehyde, C_2H_3O-H) and acetyl-methyl (acetone, $C_2H_3O-CH_3$) all belonged to the hydrogen (H—H) type. Extensions of the system to the hydrochloric acid and ammonia types will be obvious to the reader without further examples.

On the whole, the period from 1838 to 1858 was, from a theoretical standpoint, one of groping in semidarkness, of no little confusion and of heated controversy, much of it fruitless. Nevertheless, during that period, Jeremias Benjamin Richter's rather restricted views on chemical equivalency were developed into a fairly comprehensive and useful concept of valency (*q.v.*), through the contributions of Sir Edward Frankland, Alexander Edward Williamson, William Odling and others.

In the year 1858 two notable clarifying and correlating articles appeared. In one of these Archibald Scott Couper, rejecting the type theory and basing his thesis on the idea of the valencies of the elements, proceeded to develop constitutional formulas for various compounds. Through no fault of Couper's the publication of his paper was delayed until after the other (Friedrich August Kekulé's) had appeared. With due allowance for Couper's misapprehensions concerning atomic and molecular weights, his formulas much more closely resemble those in present use than did Kekulé's formulas of that time. However, Couper's interest in chemistry lapsed, and he sank into scientific obscurity, whereas Kekulé continued to develop and apply his ideas and is now generally regarded as the founder of organic structural theory.

In his original paper on this subject, Kekulé accepted the type theory, generalized and extended it, at the same time avoiding the extremism that had misled some of his contemporaries, and used it in conjunction with the radical theory. He emphasized the fact that a compound may belong at the same time to more than one type, in that it may undergo one typical reaction under one set of conditions, and an entirely different reaction under another set of conditions. He regarded the assignment of compounds to types, not as an immutable classification to be determined by the constitution of the compound in question, but merely as a convenient means of emphasizing one or more of its chemical properties, and he held that the representation that tells the most about the chemical properties of a substance is the most rational.

Kekulé thus blurred the outlines of Gerhardt's too clear-cut type classification, and extended it by adding what might be called a methane type. This addition was more than a mere extension of area, however; it altered the complexion of the whole scheme. Instead of specific types like those of Gerhardt (hydrogen, hydrochloric acid, water, ammonia), Kekulé's idea embodies essentially the four general types: univalent, bivalent, trivalent and quadrivalent. Thus, compounds of hydrogen, chlorine or any other univalent atom or radical might be assigned to a univalent type which would include both the hydrogen and hydrochloric acid types of Gerhardt. Compounds of oxygen, the methylene radical ($H_2C=$) or any other bivalent atom or radical might be assigned to a bivalent type which would include the water type of Gerhardt, etc.

Finally, Kekulé pointed out that radicals are not necessarily indestructible; that they persist throughout a given series of reactions only to suffer disintegration in other reactions.

At that time Kekulé did not regard his "rational formulas" as "representative of groupings of atoms in existing compounds"; *i.e.*, as constitutional formulas, but rather as "expressions of certain relations in metamorphoses"; *i.e.*, in chemical reactions. Indeed, he specifically pointed out in a footnote that, although the constitution of matter must be regarded as the basis of a scientific problem, the answer to the question of the actual arrangement of atoms should be sought, not in the study of chemical transformations, but rather in the comparative study of physical properties.

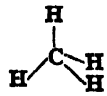
Seven years later (1865–66) Kekulé proposed for benzene (C_6H_6) the constitutional formula that is still in use today, though with some modifications in its implications in the light of modern theories of valency and interatomic binding forces. Shortly thereafter (1867) he appended to a note on the constitution of mesitylene [*sym.*-$(CH_3)_3C_6H_3$] a discussion of his views on molecular diagrams and models in which he proposed the tetrahedral carbon atom that constitutes the cornerstone of modern structural theory. With proper scientific caution, Kekulé made it clear that he did not intend all the possible physical implications of his tetrahedral model for the carbon atom to be accepted literally. Nevertheless, it became apparent during his own lifetime (1829–96) that the tetrahedral model fulfilled strictly chemical necessities that he had not at first foreseen. As Adolph von Baeyer said (1890), paraphrasing Heinrich Rudolph Hertz's comment on James Clerk Maxwell's electromagnetic theory of light, it seemed that Kekulé's molecular models were "even cleverer than their inventor."

Although the fact has no bearing on their utility and sufficiency as unique designations for all possible isomers, it is of interest to note that modern methods of physical investigation; *e.g.*, X-ray and electron diffraction studies, and, in some cases, dipole moment studies, have shown Kekulé's models to be true indicators of molecular configuration; *i.e.*, of the arrangement of atoms in space.

ORGANOCHEMICAL MODELS AND NOTATION

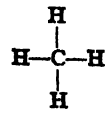
At one time chemists supposed a compound to be uniquely identified by its elementary composition. This idea was perforce abandoned when Michael Faraday discovered (1825) a hydride of carbon (later called butylene) which had the same percentage composition (carbon, 85.7%; hydrogen, 14.3%) as the "olefiant gas" (ethylene) discovered a few years earlier by John Dalton (1820). On the strength of the fact that he found butylene to have twice the vapour density of ethylene, Faraday himself offered the correct explanation, namely, that the respective molecules, although containing like proportions of the same elements, must contain different numbers of atoms, and Dalton recognized the phenomenon as a special case supporting his theory of multiple proportions.

Up to about this time the necessities of compound designation were adequately fulfilled by molecular formulas, or would have been had chemists completely mastered the concepts of atomic and molecular weights and made adequate use of the potentially available methods for the determination of molecular weights. For instance, ethylene might, without ambiguity, have been designated by the formula C_2H_4, and butylene by the formula C_4H_8.



However, when Wöhler (1823) found that some of the cyanates he had prepared had not only the same percentage compositions, but apparently the same molecular weights as fulminates prepared by Liebig and by Gay-Lussac (as well as by himself), and that both corresponded to the molecular formula MCNO (in which M represents a univalent metal), a new explanation had to be sought. Chemists, generally, hesitated to attempt an explanation until a fact so unexpected in the light of the views then current had been incontrovertibly established, although Gay-Lussac did point out in a footnote that if Wöhler's analyses were indeed correct, a different mode of combination must be assumed to account for the differences in properties of two compounds of identical composition and molecular weight.

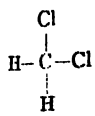
Berzelius (1827) commented on this remarkable discovery, but reserved judgment until the facts should have been more definitely established. Supplementary evidence was not long in appearing, however, for Berzelius himself (1830) found a similar example in his investigation of racemic and tartaric acids ($C_4H_6O_6$). Two years later (1832) he reviewed the field and proposed the adjective isomeric (from the Greek *ισομέρος*) to describe compounds of identical molecular formula, but unlike properties.



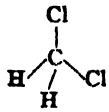
Instances of isomerism continued to multiply and were all accounted for by the general though rather vague assumption that the constituent atoms of isomeric substances must be linked together in different ways. The rapid development of a rational system of structural formulas out of Kekulé's model, and the subsequent contributions of Jacobus Henricus van't Hoff (1874), Jules Achille LeBel (1874) and Jacobus Wislicenus (1887), which eventually enabled chemists to deal adequately with problems of isomerism and to assign a unique formula to each known

compound, are described in detail in the articles on ISOMERISM and STEREOCHEMISTRY.

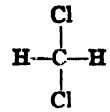
For purposes of continuity in the present discussion, it is sufficient to point out here that the extended structural formulas of the organic chemist may be regarded as representing a conventionalization of one of several possible types of projection of tetrahedral models upon a plane surface. For example, the conventionalized projection I suggests to the eye the tetrahedral configuration of the methane molecule, but the projection II is of the type more commonly employed by the organic chemist.



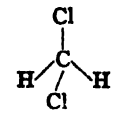
I



II

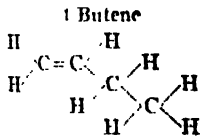


If this point were not clearly understood the projections III A and III C might be interpreted as suggesting that there are two dichloromethanes (or methylene chlorides), but comparison with the projections III B and III D, which are perhaps more readily relatable by inspection to the corresponding tetrahedral models, reveals that all four diagrams represent a single configuration—the only one possible for CH_2Cl_2.



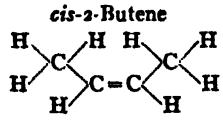
III A

III B



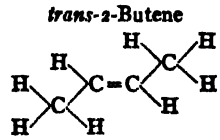
III C

III D



As a matter of practice such detailed structural formulae for relatively simple compounds are used only for elementary pedagogical purposes. In current chemical literature molecular formulas, such as CH_4 for methane, $CHCl_3$ for chloroform and C_2H_4 for ethylene, are used whenever only a single configuration for the molecule indicated is possible. Even when several isomers are known it is usually possible to use a greatly simplified notation without ambiguity, as the following examples for C_4H_8 illustrate:

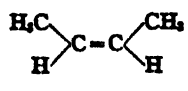
1-Butene



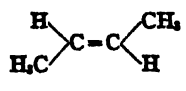
IV A

cis-2-Butene

V A



trans-2-Butene



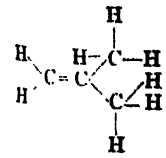
VI A

IV B

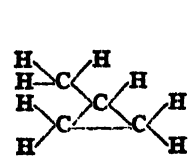
V B

VI B

IV C

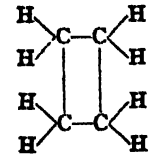


V C



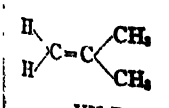
VI C

Isobutylene (2-Methylpropene)

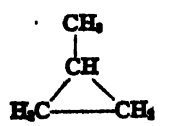


VII A

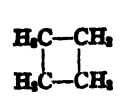
Methylcyclopropane



VIII A



Cyclobutane (Tetramethylene)



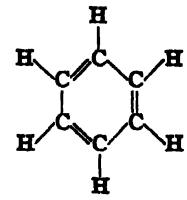
IX A

VII B

VIII B

IX B

VII C



VIII C

IX C

In full detail one of the static forms of Kekulé's benzene formula would be represented as in X A; it is more often simplified as in X B and still more often as in X C. Indeed, X C is preferable, not only on the ground of simplicity, but because it correctly implies that all carbon-to-carbon bonds in benzene are equivalent.

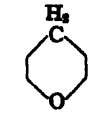
X A

X B

X C

The convention of omitting the detailed designation of doubly bonded carbon atoms and of double bonds but retaining indications of hetero atoms; *i.e.*, atoms other than carbon, and of fully hydrogenated carbon atoms in the representation of unsaturated ring structures is common. (Unsaturated is here used in the structural sense. It does not necessarily imply that the compounds have the chemical properties associated with unsaturation in the olefin series, for example. See *Classification of Organic Compounds*, aromatic compounds, below.) Thus, furan (C_4H_4O) is often represented as in XI, thiophene (C_4H_4S) as in XII, pyrrole (C_4H_5N) as in XIII, thiazole (C_3H_3NS) as in XIV, pyran (C_5H_6O) as in XV and pyridine (C_5H_5N) as in XVI.

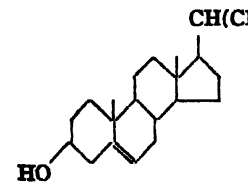
XI



XII

XIII

XIV



XV

XVI

For some other types of compounds; *e.g.*, the steroids, it has been found simpler and more economical to adopt the different convention of omitting detailed representation of carbon atoms in the cyclic nucleus but of retaining indications of double bonds. Thus, for cholesterol ($C_{27}H_{46}O$) the simplified structural formula is XVII, in which the projecting lines indicate the locations of angular methyl (CH_3) groups.

XVII

Other conventions adopted for the convenient representation of stereoisomers are discussed in the article STEREOCHEMISTRY.

The writing of chemical equations is often similarly simplified by the organic chemist by the use of suitable symbols or abbreviations and by the omission of specific representations of reactants or by-products of secondary interest. For example, nitrobenzene ($C_6H_5NO_2$) may be reduced to aniline ($C_6H_5NH_2$) by the action of metallic iron in the presence of a mineral acid. In an elementary textbook on organic chemistry the process would be represented by a complete, balanced chemical equation of the form:

$$C_6H_5NO_2 + 2Fe + 7HCl \longrightarrow C_6H_5NH_2 \cdot HCl + 2FeCl_2 + 2H_2O$$

Among the various other reactions that may be employed to effect this transformation is direct hydrogenation by means of hydrogen gas in the presence of a suitable catalyst:

$$C_6H_5NO_2 + 3H_2 \xrightarrow{(Cat.)} C_6H_5NH_2 + 2H_2O$$

Any of these processes might be indicated by the simplified equation indicating a hydrogenation reduction:

$$C_6H_5NO_2 \cdot \xrightarrow{[H]} \cdot C_6H_5NH_2$$

Similarly, the catalytic dehydrogenation of ethyl alcohol to yield acetaldehyde might be indicated by the equation

$$C_2H_5OH \xrightarrow[(Cat.)]{-H_2} CH_3CHO,$$

whereas the oxidation of ethyl alcohol by any of various oxidizing agents to yield acetic acid might be represented by

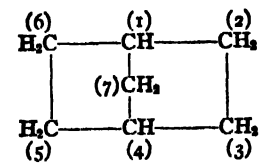
$$C_2H_5OH \cdot \xrightarrow{[O]} \cdot CH_3CO_2H$$

The application of heat is sometimes indicated by the symbol Δ in conjunction with the transitional arrow. Thus, the production of acetone by the heating of calcium acetate might be represented by:

$$(CH_3CO_2)_2Ca \xrightarrow{\Delta} (CH_3)_2CO + CaCO_3$$

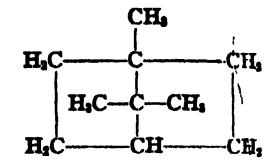
(*See* also RESONANCE, THEORY OF.)

ORGANOCHEMICAL NOMENCLATURE



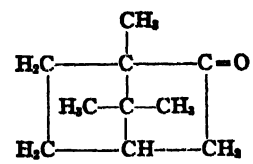
While the number of known organic compounds remained relatively small, it was the custom to name each new compound individually, usually with reference to its source, its properties or its relationship to a previously known compound. Thus, methane (CH_4) derived its name from the methylene radical (CH_2) which had been named because of its relationship to wood spirits (CH_3OH), for which a synthetic Greek name had been coined. Ethane (C_2H_6) was named because of its relationship to ether ($C_2H_5OC_2H_5$), notable for its volatility and inflammability. Propane (C_3H_8) was so-called because of its relationship to propionic acid ($C_2H_5CO_2H$), which was so named because, not being miscible with water in all proportions, it was regarded as the first of the fatty acids (*q.v.*). Butane ($CH_3CH_2CH_2CH_3$, *n*-C_4H_{10}) was named for its relationship to butyric acid (*n*-$C_3H_7CO_2H$), which had been isolated as a hydrolysis product of butter. Isobutane $CH(CH_3)_3$, *i*-C_4H_{10} was so-called because it had the same composition and molecular weight as butane.

Such names are now known as trivial names, for they do not of themselves clearly indicate the structures of the compounds they represent.

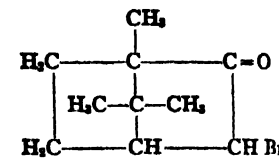


As the number of known organic compounds grew, the necessity for a systematization of nomenclature became increasingly evident. Notwithstanding various sporadic attempts at reform and rationalization, the first significant and generally influential achievement in this respect was the formulation of a series of 52 rules by about 40 representatives of various countries at the Geneva congress of 1892. Some of the rules of the Geneva congress found general favour but others did not, and large parts of the field were left uncovered. In 1930 the "Definitive Report of the Commission on the Reform of the Nomenclature of Organic Chemistry" was unanimously adopted by the commission and council of the International Union of Chemistry, meeting at Liège, Belgium. Its 68 rules are based on those of the Geneva congress, but with many changes and additions. Further amplifications were adopted in 1936 and 1938. In general practice the rules of the International union require interpretation and extension. The most reliable guides to good usage in (English) organochemical nomenclature are the current annual and decennial subject indices of *Chemical Abstracts*, published by the American Chemical society. An excellent presentation of the International union rules, together with illustrations, interpretative discussions and supplementary appendixes is to be found in the introduction to the subject index for 1945, *Chemical Abstracts*, 39, pp. 5,867–5,975 (1945).

In the systematic nomenclature common or trivial names of long standing and universal adoption have been retained, and a certain flexibility is permitted in the systematic naming of other compounds. Therefore, many organic compounds may be said to have more than one correct name. Thus, the common name isobutane and the systematic name methylpropane are both correctly applied to the hydrocarbon $CH(CH_3)_3$. Normal pentane is both the common and the systematic name for the hydrocarbon $CH_3(CH_2)_3CH_3$. Isopentane and methylbutane are the common and systematic names respectively, for the hydrocarbon $CH_3CH_2CH(CH_3)_2$; neopentane and dimethylpropane are the common and systematic names, respectively, for the hydrocarbon $C(CH_3)_4$. Likewise, methyl alcohol (CH_3OH), the compound of a methyl radical with a hydroxyl group, is also correctly called carbinol, or methanol, the compound derived by substituting a hydroxyl group for a methane hydrogen atom; and ethyl alcohol (C_2H_5OH) may also be called methylcarbinol or ethanol. Acetic acid (CH_3CO_2H) is also ethanoic acid, the acid derived by converting one of the methyl groups of ethane to a carboxyl group (CO_2H), or methanecarboxylic acid, the acid derived by substituting a carboxyl group for a methane hydrogen atom. Acetone (CH_3COCH_3), the ketone derived from acetic acid (as by the pyrolysis of calcium acetate), is also dimethyl ketone, or propanone, the ketone structurally related to propane ($CH_3CH_2CH_3$).



For the simpler organic compounds, which are in most cases among those longest known, the common (or trivial) names are usually preferred by reason of long usage. For more complicated compounds common names are often preferable because the systematic names become inconveniently cumbersome. Camphor (XX), a ketone related to camphane (XIX), which is in turn a derivative of norcamphane (XVIII), one of the bicycloheptanes, furnishes an example:



Norcamphane (XVIII)
Bicyclo[2.2.1]heptane

Camphane (XIX)
1,7,7-Trimethylbicyclo[2.2.1]-heptane

Camphor (XX)
2-Camphanone
1,7,7-Trimethylbicyclo[2.2.1]-heptan-2-one

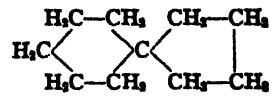
α-Camphoryl bromide (XXI)
3-Bromo-2-camphanone
1,7,7-trimethyl-3-bromobicyclo[2.2.1]heptan-2-one

Obviously, a comprehensive treatment of the subject of nomenclature is neither possible nor necessary in an article of this kind However, further nomenclatural information will be supplied wherever it is necessary to an understanding of the discussion in succeeding sections.

CLASSIFICATIONS OF ORGANIC COMPOUNDS

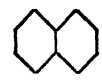
Aside from more or less artificial systems devised for indexing purposes, various methods of classifying organic compounds are in common use.

Classification Primarily on the Basis of Chemical Composition.—No serious attempt has been made to expand this method of classification into a general system, but it has been found useful in defining certain classes of compounds. To cite a few illustrative examples, hydrocarbons (*q.v.*), comprise the class of compounds composed solely of carbon and hydrogen.



The terpenes are a special class of hydrocarbons, defined by the general formula $(C_5H_8)_n$, and including: the hemiterpenes, C_5H_8, such as isoprene and pentadiene; the simple terpenes, $C_{10}H_{16}$, such as bornylene, camphene, limonene, pinene, terpinene, etc.; the sesquiterpenes, $C_{15}H_{24}$, such as cedrene, clovene, patchoulene, santalene, etc; the diterpenes, $C_{20}H_{32}$, the polyterpenes, $(C_{10}H_{16})_n$. For convenience other hydrocarbons derived by hydrogenation, or dehydrogenation of the parent terpenes, as well as various derived alcohols, aldehydes, ketones, acids, etc., are sometimes classed together with the terpenes as terpenoid substances.

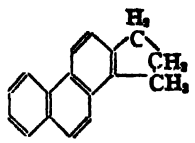
The carbohydrates (*q.v.*), generally speaking, have the composition indicated by the general formula $C_x(H_2O)_y$. By common consent some compounds whose formulas correspond to the gen-



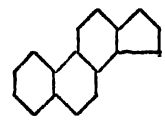
eral formula; *e.g.*, acetic acid, CH_3CO_2H, $C(H_2O)_2$, are excluded from the classification because their chemical properties differ fundamentally from those of the majority of the carbohydrates; whereas other compounds; *e.g.*, rhamnose, $C_6H_{12}O_5$, whose formulas do not correspond exactly to the general formula, are arbitrarily classified with the carbohydrates because of their chemical characteristics.

Classification on the Basis of Structure.—Several classifications of general applicability, though rather limited utility, may be made on the basis of structure. For example, all organic compounds might be classified either as structurally saturated; *i.e.*, as containing only single bonds, or structurally unsaturated; *i.e.*, as containing one or more multiple bonds, or resonance hybrids thereof.

A different system of structural classification assigns all organic compounds to acyclic (open-chain), cyclic or hybrid cyclic-acyclic classes. The cyclic and cyclic-acyclic classes are subdivisible structurally into monocyclic, bicyclic, tricyclic or polycyclic classes. Bicyclic compounds may be of the spiro type (having one and only one atom common to each ring) as in the case of spiro[4.5]decane (XXII) or of the condensed-ring type (having two or more atoms common to each ring), as in the cases of norcamphane (XVIII) and naphthalene (XXIII).



XXII



XXIII

Subclassification of cyclic compounds may also be made on the basis of composition into homocyclic and heterocyclic compounds. Rings of the former class are composed of carbon members only: benzene (X A, B, C), cyclobutane (IX A, B, C), norcamphane (XVIII), spiro[4.5]decane (XXII) and naphthalene (XXIII) are examples. Rings of the latter class include members other than carbon: furan (XI), thiophene (XII), pyrrole (XIII), thiazole (XIV), pyran (XV) and pyridine (XVI) are examples.

More limited classifications on the basis of structure are sometimes made for the purpose of defining types of compounds. For example, the steroids, of which cholesterol (XVII) may serve as an example, may be defined as derivatives or structural relatives of cyclopenta[*a*]phenanthrene (XXIV) or, as some organic chemists would prefer, of perhydrocyclopenta[*a*]phenanthrene (XXV).

XXIV

XXV

Classification on the Basis of Chemical Properties.—Organic compounds are often divided, primarily on the basis of chemical properties, into two classes—aliphatic and aromatic. The aliphatic compounds were originally so named because of their relationship to the fatty acids; the aromatic compounds were so-called because many of the earlier-known representatives of the class have distinctive odours, and were therefore described as aromatic. Although it is impossible to define the two classes concisely in a mutually exclusive manner, there is seldom any disagreement among organic chemists as to the assignment of a specific individual compound to its proper class. Briefly, and approximately, the acyclic and saturated, or more nearly saturated (structurally speaking), cyclic compounds belong to the aliphatic series; the more highly unsaturated cyclic compounds belong to the aromatic series. The acyclic hydrocarbons may, perhaps, be regarded as the prototypes of the aliphatic series, and benzene as the principal prototype of the aromatic series. Some compounds are in part aliphatic and in part aromatic; toluene ($C_6H_5CH_3$), ethylbenzene ($C_6H_5CH_2CH_3$), styrene ($C_6H_5CH{=}CH_2$) and stilbene ($C_6H_5CH{=}CHC_6H_5$) are examples. Such compounds are usually assigned to one class or the other with respect to the particular reaction under consideration. For example, in the reaction

$$C_6H_5CH_3 + Br_2 \longrightarrow BrC_6H_4CH_3 + HBr,$$

toluene reacts as an aromatic compound, whereas in the reaction

$$C_6H_5CH_3 + Br_2 \longrightarrow C_6H_5CH_2Br + HBr,$$

it reacts as an aliphatic compound. Because the two types of reaction—aromatic halogenation by hydrogen substitution and aliphatic halogenation by hydrogen substitution—differ in mechanism, it is possible to carry out either reaction to the almost total exclusion of the other by an appropriate selection of experimental conditions.

The ultimate criterion determining the assignment of a structurally unsaturated cyclic compound to the aromatic or aliphatic class is the similarity of its chemical properties to those of benzene on the one hand or to those of the olefins (*q.v.*), on the other. In general, aliphatic compounds (and especially unsaturated aliphatic compounds) are considerably more susceptible to oxidation than are aromatic compounds. It is usually possible, therefore, to effect selective oxidation of the aliphatic portion of a hybrid molecule without appreciable attack upon the aromatic portion. In the case of toluene, oxidation to benzoic acid may be carried out almost quantitatively by a suitable choice of oxidizing agent and experimental conditions:

$$C_6H_5CH_3 \xrightarrow{[O]} C_6H_5CO_2H + 1.5\ H_2O$$

The difference between aliphatic and aromatic halogenations by hydrogen substitution has already been mentioned. In general, the aliphatic halogenations are initiated or facilitated by the presence of organic peroxides or a small amount of oxygen in the reaction system, or by the application of light, and are favoured by relatively low initial halogen concentrations (constantly renewed as halogen is expended). In general, aromatic substitutive halogenations are favoured by relatively high initial halogen concentrations and are expedited by metallic halide catalysts such as ferric chloride ($FeCl_3$) or ferric bromide ($FeBr_3$).

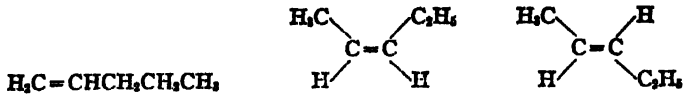
Most unsaturated aliphatic compounds react additively with bromine, chlorine, hydrogen chloride, hydrogen bromide, hydrogen iodide and concentrated sulphuric acid at ordinary temperatures:

$$RCH{=}CH_2 + Br_2 \longrightarrow RCHBrCH_2Br;$$
$$RR'C{=}CHR'' + HCl \longrightarrow RR'CClCH_2R'';$$
$$RCH{=}CH_2 + H_2SO_4 \longrightarrow RCH(OSO_3H)CH_3$$

Aromatic hydrocarbons, although structurally unsaturated, do not undergo these reactions under the same conditions.

Many aliphatic compounds are oxidized by fuming nitric acid or by nitrating acid (a mixture of concentrated nitric and sulphuric acids) at room, or slightly elevated, temperatures. Under similar conditions aromatic compounds are nitrated:

$$C_6H_6 + HNO_3 \longrightarrow C_6H_5NO_2 + H_2O$$



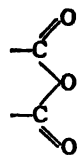
Most saturated (aliphatic) hydrocarbons are unaffected by concentrated or fuming sulphuric acid at or near room temperature. Under similar conditions most aromatic compounds undergo sulphonation:

$$C_6H_6 + H_2SO_4 \longrightarrow C_6H_5SO_3H + H_2O$$

In addition to division into the two major classes, aliphatic and aromatic, organic compounds may be classified more minutely according to their so-called functional groups. The concept of function is essentially an editorial invention and has a significance established by usage rather than by precise definition. According to *Chemical Abstracts*, 39, p. 5,876 (1945), "It is customary to use the term 'function' to mean, in its broadest sense, any atom, group or arrangement which causes a compound to behave in some characteristic way." Nomenclaturally, some functions are denoted only by suffixes, some only by prefixes and many by either suffixes or prefixes according to circumstances.

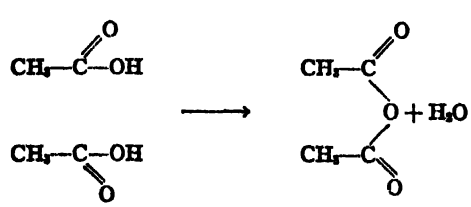
In the broad sense of the foregoing quotation a carbon-to-carbon double bond is a function, denoted in the systematic nomenclature by the suffix -ene. Thus, the olefins (*q.v.*) comprise a class of acyclic unsaturated hydrocarbons characterized by the carbon-to-carbon double-bond function and designated in

the systematic nomenclature by the generic term alkenes. Specific examples: 1-pentene (XXVI), *cis*-2-pentene (XXVII), *trans*-2-pentene (XXVIII).



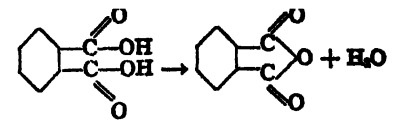
XXVI XXVII XXVIII

Similarly, the acetylenes comprise a class of acyclic unsaturated hydrocarbons characterized by the carbon-to-carbon triple-bond function (denoted by the suffix -yne) and designated in the systematic nomenclature by the generic term alkynes. Specific examples: acetylene (ethyne), HC≡CH; methylacetylene (propyne), HC≡CCH$_3$; 1-butyne, HC≡CC$_2$H$_5$; 2-butyne, H$_3$CC≡CCH$_3$.



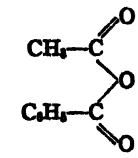
The organic acids fall into several classes corresponding to the several acidic functional groups. Among the more common organic acids are the carboxylic acids, characterized by the carboxyl group (−CO$_2$H), and the sulphonic acids (*q.v.*), characterized by the sulpho group (−SO$_3$H). Specific examples: acetic acid (ethanoic acid, methanecarboxylic acid, carboxymethane), CH$_3$CO$_2$H; benzoic acid (benzenecarboxylic acid, carboxybenzene), C$_6$H$_5$CO$_2$H; benzenesulphonic acid (sulphobenzene), C$_6$H$_5$SO$_3$H.

Among the compounds more or less closely related to the acids in a functional sense are the acyl halides, the esters (*q.v.*), the amides (*q.v.*) and the amidines (*q.v.*). All of these except the last may be regarded, formally, as organic acids in which an acidic hydroxyl group has been replaced by another group or atom. For example, a carboxylic acid may be represented by the general formula RCO.OH, and a sulphonic acid by the general formula RSO$_2$.OH. The corresponding acid halides may then be represented by the general formulas RCO.X and RSO$_2$.X, respectively, the corresponding esters by the formulas RCO.OR′ and RSO$_2$.OR′, respectively, and the corresponding amides by the formulas RCO.NH$_2$ and RSO$_2$.NH$_2$, respectively. The amidines are derivatives of the carboxylic acids and may be characterized by the general formula RC(=NH)NH$_2$. Specific examples of acyl derivatives: acetyl bromide (CH$_3$CO.Br); methyl acetate (CH$_3$CO.OCH$_3$); acetamide (CH$_3$CO.NH$_2$); acetamidine CH$_3$C(=NH)NH$_2$; benzenesulphonyl chloride (C$_6$H$_5$SO$_2$.Cl); benzenesulphonamide (C$_6$H$_5$SO$_2$.NH$_2$); ethyl benzenesulphonate (C$_6$H$_5$SO$_2$.OC$_2$H$_5$).

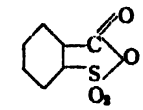


Another important class of acid derivatives comprises the acid anhydrides (*q.v.*). The anhydrides of the carboxylic acids are distinguished by the grouping

As the name suggests, these compounds may be regarded as dehydration products of the acids. As such they may arise, either from intermolecular dehydration of two molecules of monocarboxylic acid, or from intramolecular dehydration of one molecule of dicarboxylic acid.



(Acetic acid) (Acetic anhydride)



(Phthalic acid) (Phthalic anhydride)

Mixed anhydrides, derived from one molecule each of two different acids, are known; *e.g.*, acetic benzoic anhydride (XXIX).

XXIX

Another type of mixed anhydride is that exemplified by the anhydride of ortho-sulphobenzoic acid (XXX).

XXX

Alcohols (*q.v.*), phenols and naphthols have in common the hydroxyl function (-OH) and are, therefore, hydroxylic compounds. This function is denoted by the prefix hydroxy- or by the suffix -ol. In terms of the general formula ROH, which may be applied to all monohydroxylic compounds, R signifies an aliphatic radical if the compound is an alcohol, a benzenoid radical if the compound is a phenol or a naphthalenic radical if the compound is a naphthol. Some authors loosely classify all aromatic hydroxylic compounds as phenolic substances. Specific examples: ethyl alcohol (ethanol, hydroxyethane), C$_2$H$_5$OH; benzyl alcohol (α-hydroxytoluene), C$_6$H$_5$CH$_2$OH; phenol (hydroxybenzene), C$_6$H$_5$OH; α-naphthol (1-naphthol, 1-hydroxynaphthalene, XXXI); β-naphthol (2-naphthol, 2-hydroxynaphthalene, XXXII).

XXXI XXXII

The carbonyl (>C=O) function is common to the aldehydes (*q.v.*), which may be characterized by the general formula RCHO, and the ketones (*q.v.*), which may be characterized by the general formula RCOR′. (Although this grouping also appears in the static formulas for the carboxylic acids and their functional derivatives, those compounds are usually regarded as belonging to separate classes of their own.) In the systematic nomenclature aldehydes are designated by the suffix -al, and ketones by the suffix -one. Specific examples: formaldehyde (methanal), HCHO; acetaldehyde (ethanal), CH$_3$CHO; acetone (propanone), CH$_3$COCH$_3$; diethyl ketone (3-pentanone), (C$_2$H$_5$)$_2$CO; cyclohexanone, (CH$_2$)$_5$CO.

The acetals and ketals are closely related to the aldehydes and ketones and have, respectively, the general formulas RCH(OR′)$_2$ and RR′C(OR″)$_2$.

The amines (*q.v.*) may be regarded as organic derivatives of ammonia (NH$_3$). Primary amines correspond to the general formula RNH$_2$, secondary amines to the formula RR′NH and tertiary amines to the formula RR′R″N. The amines are characterized by the prefix amino- and the suffix -amine. Specific examples: methylamine (aminomethane), CH$_3$NH$_2$; aniline (phenylamine, aminobenzene), C$_6$H$_5$NH$_2$; diethylamine, (C$_2$H$_5$)$_2$NH; dimethylaniline (phenyldimethylamine, dimethylaminobenzene), (CH$_3$)$_2$NC$_6$H$_5$.

The organic cyanides are characterized by the nitrile (-CN)

function and have the general formula RCN. The appropriate prefix is cyano-, and the suffix -nitrile. Specific examples: acetonitrile (cyanomethane), CH_3CN; benzonitrile (cyanobenzene), C_6H_5CN.

Monohalogenated compounds may be designated by the general formula RX, in which X signifies a halogen—fluorine, chlorine, bromine or iodine. They may be named either as organic halides (specifically, fluorides, chlorides, bromides, iodides) or as halocompounds (fluoro-, chloro,- bromo-, iodo-). Specific examples: ethyl bromide (bromoethane), C_2H_5Br; isopropyl iodide (2-iodopropane), $(CH_3)_2CHI$; chlorobenzene (phenyl chloride), C_6H_5Cl.

The foregoing summary is by no means an exhaustive compilation of types of organic compounds or of the functional groups that characterize them. A supplementary, though still incomplete, listing might include the following groups: azo- (—N=N—); hydrazino- (H_2NNH—); hydrazo- (—HNNH); hydroxamino- (HONH—); imino- (imido- in acid groups) (NH=); iodoso- (OI—); iodoxy- (O_2I—); isocyano- (CN—); isonitroso- (HON=); nitro- (O_2N—); nitroso- (ON—); phosphino- (H_2P—); phospho- (O_2P—); phosphono- [$(HO)_2OP$—]; selenyl- (HSe—); stibino- (H_2Sb—); sulphino- (HO_2S); sulphinyl- (OS=) sulphonyl- ($-SO_2-$); thiocarbonyl (SC=); thiocyano- (NCS—); triazo- (N_3—).

If a compound contains but one kind of functional group, it is said to be of simple function; if two or more of such groups are present the compound is said to be of multiple function. A compound of mixed or complex function is one which contains more than one kind of function.

Classifications on the Basis of Properties Other Than Chemical.—For various reasons groups of compounds widely divergent in structure and chemical nature, but having in common some other quality, characteristic or property, are sometimes classified together.

For example, the vitamins, comprising a considerable variety of structural and chemical types, have in common the quality that all are essential constituents of a normal diet, and that when they are absent from the diet or present in insufficient amount, one or more of a variety of deficiency diseases ensues.

The plastics are materials of high molecular weight formed by the condensation or polymerization of units of usually one or two, but always few, molecular species. In the broadest sense of the term the class includes: the thermosetting plastics; *e.g.*, Bakelite, which may be moulded by the application of heat and pressure, but which, once moulded, do not soften upon reheating; the thermoplastics; *e.g.*, Lucite, which may be reheated and remoulded indefinitely; the elastomers, which include the wide range of synthetic rubbers; the synthetic resins and many other substances.

The hormones, representing a variety of chemical types, are secretions of the endocrine glands and serve as the regulators of numerous and diverse bodily functions.

Dyes, or dyestuffs, may be divided into several chemical classes but have in common the ability to combine with and colour textiles or other materials.

ORGANIC REACTIONS

Organic reactions, like organic compounds, are subject to many schemes of classification and designation. Among the least systematic methods is that of designating a reaction or class of reactions by the name (or names) of its discoverer (or discoverers). Sometimes this method of designation results in the co-classification of a wide variety of reactions which are only superficially related to each other, as for example, in the case of the Grignard reactions (named after Victor Grignard). The Grignard reactions may be defined as the reactions of the Grignard reagents (*q.v.*), or the organomagnesium halides (RMgX). Some idea of the considerable variety of reactions thus grouped in a single class may be formed from the following incomplete set of examples of typical Grignard reactions:

$CH_3MgCl + H_2O \longrightarrow CH_4 + MgClOH$;

$si\text{-}C_4H_9MgBr + O_2 \longrightarrow si\text{-}C_4H_9OMgBr \xrightarrow{(H_2O)} si\text{-}C_4H_9OH + MgBrOH$;

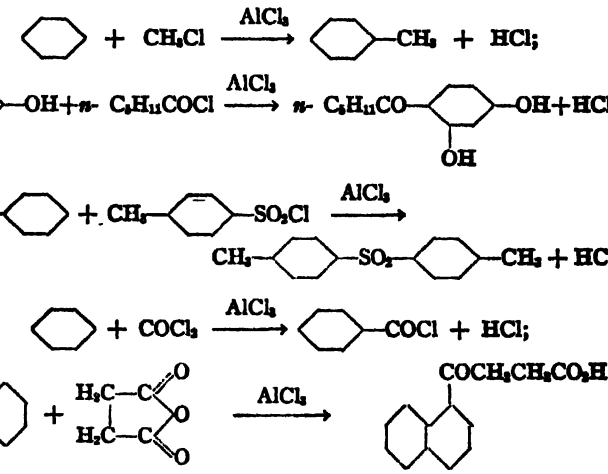
$\alpha\text{-}C_{10}H_7MgBr + CO_2 \longrightarrow \alpha\text{-}C_{10}H_7CO_2MgBr \xrightarrow{(H_2O)} \alpha\text{-}C_{10}H_7CO_2H + MgBrOH$;

$C_6H_5CH_2C{\equiv}CMgBr + I_2 \longrightarrow C_6H_5CH_2C{\equiv}CI + MgBrI$;

$(C_6H_5)_3CMgBr + CH_2{=}CHCH_2Br \longrightarrow (C_6H_5)_3CCH_2CH{=}CH_2 + MgBr_2$;

$CH_3MgI + C_6H_5CHO \longrightarrow CH_3(C_6H_5)CHOMgI \xrightarrow{(H_2O)} CH_3(C_6H_5)CHOH + MgIOH$;

$CH_2{=}CHCH_2MgBr + CH_3COC_2H_5 \longrightarrow CH_3(C_2H_5)(CH_2{=}CHCH_2)COMgBr \xrightarrow{(H_2O)} CH_3(C_2H_5)(CH_2{=}CHCH_2)COH + MgBrOH$;



$C_6H_5MgBr + HC(OC_2H_5)_3 \longrightarrow C_6H_5CH(OC_2H_5)_2 + MgBrOC_2H_5$;

$2n\text{-}C_5H_{11}MgBr + CH_3CO_2C_2H_5 \longrightarrow CH_3(n\text{-}C_5H_{11})_2COMgBr + MgBrOC_2H_5 \xrightarrow{(H_2O)} CH_3(n\text{-}C_5H_{11})_2COH + C_2H_5OH + 2\,MgBrOH$;

$C_2H_5MgBr + C_6H_5COCl \longrightarrow C_2H_5COC_6H_5 + MgBrCl$;

$\alpha\text{-}C_{10}H_7MgBr + \alpha\text{-}C_{10}H_7CN \longrightarrow (\alpha\text{-}C_{10}H_7)_2C{=}NMgBr \xrightarrow{(H_2O)} (\alpha\text{-}C_{10}H_7)_2C{=}NH + MgBrOH$

Similarly, the Friedel-Crafts reactions (named after Charles Friedel and James Mason Crafts) embrace a variety of transformations, all having in common the characteristics that they result in substitutions in an aromatic ring and are catalyzed by anhydrous aluminum chloride ($AlCl_3$) or similar catalysts:

On the other hand, this method of classifying reactions sometimes leads to the designation of more or less closely related reactions by a number of different names depending upon the specific reactants involved or the catalysts employed, or both. For example, the aldol condensations, the Claisen, the Knoevenagel and the Perkin reactions are all catalyzed condensations involving a carbonyl group (>C=O) and a reactive methylidyne (HC=), methylene (H_2C=) or methyl (H_3C—) group:

$2CH_3CHO \xrightarrow{OH^-} CH_3CH(OH)CH_2CHO$ (aldol);

$2CH_3CHO \xrightarrow[\Delta]{SiO_2} CH_3CH{=}CHCHO + H_2O$ (aldol + dehydration);

$C_6H_5CHO + CH_3COCH_3 \xrightarrow{OH^-} C_6H_5CH{=}CHCOCH_3 + H_2O$ (Claisen);

$CH_3COCH_3 + H_2C(CN)CO_2C_2H_5 \xrightarrow{(CH_2)_5NH} (CH_3)_2C{=}C(CN)CO_2C_2H_5 + H_2O$ (Knoevenagel);

$C_6H_5CHO + (CH_3CO)_2O \xrightarrow{CH_3CO_2Na} C_6H_5CH{=}CHCO_2Na + CH_3CO_2H$ (Perkin)

Among the numerous possible systematic classifications of organic reactions an arbitrary choice is made for the purposes of this discussion. According to the system adopted organic reactions fall into four principal classes: (1) those in which the original carbon skeleton of the chief reactant is unchanged but which result in the introduction, removal, replacement or alteration of

substituent atoms or groups; (2) those in which the original carbon skeleton undergoes an alteration in structure, but without loss or gain of carbon; (3) those in which the carbon skeleton is augmented and (4) those in which a cleavage of one or more carbon-to-carbon bonds takes place, with fragmentation of the original carbon skeleton.

Class 1. Introduction, Removal, Replacement or Alteration of Substituent Atoms or Groups.—Although hydrogen is not ordinarily regarded as a substituent, for the term derives from the fact that the substituent group may be regarded, formally, at least, as having been substituted for hydrogen, the hydrogenation of unsaturated compounds properly falls in the class of reactions which do not alter the carbon skeleton. Such reactions are usually effected with the aid of a suitable catalyst, such as finely divided nickel, platinum or palladium, and hydrogen gas is usually introduced into the reaction system under pressure. Thus, acetylene (C_2H_2) may be partially hydrogenated to ethylene (C_2H_4) or fully hydrogenated to ethane (C_2H_6); or benzene (C_6H_6) may be hydrogenated to cyclohexane (C_6H_{12}):

$$HC{\equiv}CH \xrightarrow[(Cat.)]{+H_2} H_2C{=}CH_2 \xrightarrow[(Cat.)]{+H_2} H_3C{-}CH_3;$$

$$C_6H_6 + 3H_2 \xrightarrow{(Cat.)} (CH_2)_6$$

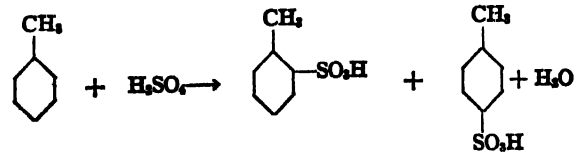
Large quantities of unsaturated vegetable oils, such as cottonseed and peanut oils, are partially hydrogenated in this way to produce solid or semisolid fats.

Reactions in which two or more reactant molecules combine to form a single molecule of product are sometimes called additive reactions or addition reactions. Reagents other than hydrogen, which react additively with many unsaturated compounds, either spontaneously or under the influence of catalysts, are the halogens (Br_2, Cl_2), the halogen acids (HI, HBr, HCl), sulphuric acid (H_2SO_4) and water (H_2O):

$$RC{\equiv}CH \xrightarrow{+Cl_2} RCCl{=}CHCl \xrightarrow{+Cl_2} RCCl_2CHCl_2;$$

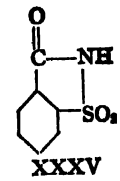
$$RCH{=}CH_2 \xrightarrow{+HI} RCHICH_3;$$

$$RCH{=}CH_2 \xrightarrow{+H_2SO_4} RCH(OSO_3H)CH_3;$$



$$RC{\equiv}CH + H_2O \xrightarrow{(HgSO_4 + H_2SO_4)} [RC(OH){=}CH_2] \longrightarrow RCOCH_3$$

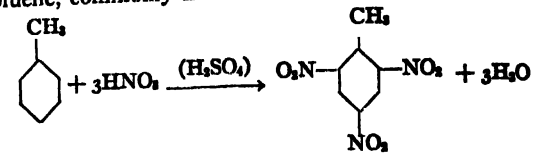
Sometimes the same product may be obtained either by an addition reaction of an unsaturated compound or by the replacement of hydrogen. For example, isopropyl bromide (2-bromopropane, $CH_3CHBrCH_3$) may be obtained either by the addition of hydrogen bromide to propylene (propene, $CH_3CH{=}CH_2$) or by the bromination of propane ($CH_3CH_2CH_3$):



$$CH_3CH{=}CH_2 + HBr \longrightarrow CH_3CHBrCH_3;$$

$$CH_3CH_2CH_3 + Br_2 \longrightarrow CH_3CHBrCH_3 + HBr$$

Among the hydrogen-substitution reactions that have attained considerable industrial importance are the aromatic sulphonations and nitrations by means of which many dyestuff and pharmaceutical intermediates and other commodities are produced. For example, the sulphonation of toluene ($C_6H_5CH_3$) yields a mixture of ortho- (XXXIII) and para-toluenesulphonic acids (XXXIV), the former of which finds one of its uses in the production of saccharin (XXXV).



XXXIII XXXIV

XXXV

Although the introduction of a sulpho or a nitro group into a benzene nucleus leads to a product less susceptible to further sulphonation or nitration than the original reactant, it is possible to introduce three nitro groups into toluene to produce 2,4,6-trinitrotoluene, commonly known as T.N.T.

The removal of a functional group may sometimes be effected with the introduction of unsaturation or through the replacement of the functional group by hydrogen. Although the former process is in effect the reverse of an addition reaction, the halide obtained by addition of the appropriate hydrogen halide to the olefin obtained by dehydrohalogenation of a halide is not always identical with the original halide, as the following example illustrates:

$$(CH_3)_2CHCH_2Br + \text{alcoholic KOH} \longrightarrow (CH_3)_2C{=}CH_2 + KBr + H_2O;$$

$$(CH_3)_2C{=}CH_2 + HBr \longrightarrow (CH_3)_2CBrCH_3$$

Some other possible dehalogenations with resultant unsaturation are illustrated by the following examples:

$$RCHBrCH_2Br + 2KOH\ (alc.) \longrightarrow RC{\equiv}CH + 2KBr + 2H_2O;$$

$$RCHBrCH_2Br + Zn \longrightarrow RCH{=}CH_2 + ZnBr_2$$

The hydroxyl group is another functional group which may be removed with the introduction of unsaturation. In general tertiary alcohols are readily, secondary alcohols less readily and primary alcohols with relative difficulty, dehydrated to olefins. Some tertiary alcohols lose water quantitatively when distilled at atmospheric pressure; a wide variety of acidic catalysts, as well as alumina (Al_2O_3) and silica gel (SiO_2), have been used to facilitate more difficult dehydrations:

$$RR'C(OH)CH_2R'' \quad . RR'C{=}CHR'' + H_2O;$$

$$RCH(OH)CH_2R'' \xrightarrow{(KHSO_4)} RCH{=}CHR' + H_2O;$$

$$RCH_2CHOH \xrightarrow{(Al_2O_3)} RCH{=}CH_2 + H_2O$$

The replacements of functional groups by hydrogen are in general oxidation-reduction reactions (*see* OXIDATION AND REDUCTION), usually called reductions because the principal organic reactant undergoes reduction. Many alkyl iodides are readily reduced by hydrogen iodide,

$$RI + HI \longrightarrow RH + I_2$$

The halogen of most alkyl halides may be directly replaced by hydrogen with the aid of catalysts of the type used to facilitate the hydrogenation of unsaturated compounds,

$$RX + H_2 \xrightarrow{(Cat.)} RH + HX$$

Occasionally, the replacement is effected indirectly, as by the formation and subsequent hydrolysis of a Grignard reagent,

$$RX \xrightarrow{Mg} RMgX \xrightarrow{H_2O} RH + MgXOH$$

Relatively few alcohols may be reduced directly;

$$ROH \xrightarrow{[H]} RH + H_2O$$

reduction is usually effected indirectly, either by conversion to a

halide with subsequent reduction, or by dehydration and subsequent hydrogenation:

$$ROH \xrightarrow{HX} RX + H_2O \xrightarrow{[H]} RH + HX;$$

$$RR'C(OH)CH_3 \xrightarrow[\Delta]{(Cat.)} RR'C{=}CH_2 + H_2O \xrightarrow[(Cat.)]{+H_2} RR'CHCH_3$$

Unlike the alcohols, the aldehydes (RCHO) and ketones (RCOR') are, in general, readily reducible to the corresponding hydrocarbons:

$$RCHO \xrightarrow{[H]} RCH_3 + H_2O;$$

$$RCOR'' \xrightarrow{[H]} RCH_2R' + H_2O$$

The replacement of one functional group by another may sometimes be effected by a true exchange reaction; more often it is accomplished by indirect means. Among the true exchange reactions may be cited: (1) the hydrolysis of many alkyl halides to the corresponding alcohols (usually alkali-catalyzed); (2) the conversion of secondary and tertiary alcohols to halides by treatment with the appropriate halogen acid; (3) the conversion of alkyl bromides or chlorides to iodides by treatment with potassium iodide (KI) and (4) the conversion of alkyl halides to amines (*q.v.*), by treatment with ammonia (NH_3). The latter process, however, invariably leads to a mixture of products, namely, the primary, secondary and tertiary amines:

$$\begin{aligned}
&(1)\ RX + H_2O \xrightarrow{(OH^-)} ROH + HX;\\
&(2)\ ROH + HX \rightarrow RX + H_2O;\\
&(3)\ RBr + KI \rightarrow RI + KBr;\\
&(4)\ RX + NH_3 \rightarrow RNH_2 + NH_4^+X^- + R_2NH + R_3N
\end{aligned}$$

In general nitro (NO_2) groups are converted to amino (NH_2) groups by any one of a variety of reduction processes,

$$RNO_2 \xrightarrow{[H]} RNH_2 + 2H_2O$$

Nitriles may be converted by partial hydrolysis to amides, or by complete hydrolysis to the corresponding carboxylic acids,

$$RCN \xrightarrow{+H_2O} RCONH_2 \xrightarrow[+HX]{+H_2O} RCO_2H + NH_4^+X^-$$

The carboxyl groups of carboxylic acids may be variously modified, and numerous interconversions of carboxylic acid derivatives are possible:

$$\begin{aligned}
&RCO_2H + R'OH \xrightarrow{(H^+)} RCO_2R' + H_2O;\\
&RCO_2H + SOCl_2 \rightarrow RCOCl + HCl + SO_2;\\
&RCO_2R' + NH_3 \rightarrow RCONH_2 + R'OH;\\
&RCOCl + R'OH \rightarrow RCO_2R' + HCl;\\
&RCOCl + R'NH_2 \rightarrow RCONHR' + HCl
\end{aligned}$$

In general, secondary alcohols (RR'CHOH) are readily converted to ketones (RCOR') by mild oxidation,

$$RR'CHOH \xrightarrow{[O]} RCOR' + H_2O$$

Similarly, many primary alcohols (RCH_2OH) may be converted to aldehydes (RCHO) by dehydrogenation (which is essentially an oxidation process) by means of heating in the presence of a suitable catalyst,

$$RCH_2OH \xrightarrow[\Delta]{(Cat.)} RCHO + H_2$$

The converse reductions are likewise possible:

$$RCOR' \xrightarrow{[H]} RR'CHOH;$$

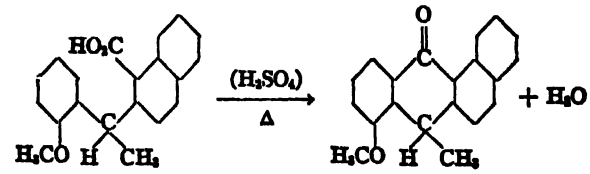
$$RCHO \xrightarrow{[H]} RCH_2OH$$

The foregoing examples are offered merely as illustrations; no attempt is made to present a complete résumé of organic reactions.

Class 2. Alteration in Structure of the Carbon Nucleus. —Among the many reactions that fall into this class are a variety of molecular rearrangements. Illustrative are: (1) the pinacol-pinacolone rearrangements

$$R_2C(OH)C(OH)R_2 \xrightarrow[(H_2SO_4)]{} R_3CCOR;$$

(2) the benzilic acid rearrangement



$$C_6H_5COCOC_6H_5 + KOH \rightarrow (C_6H_5)_2C(OH)CO_2K$$

and (3) the Wagner rearrangements

$$R_2CCH(OH)R \xrightarrow{(H^+)} R_2C{=}CR_2 + H_2O$$

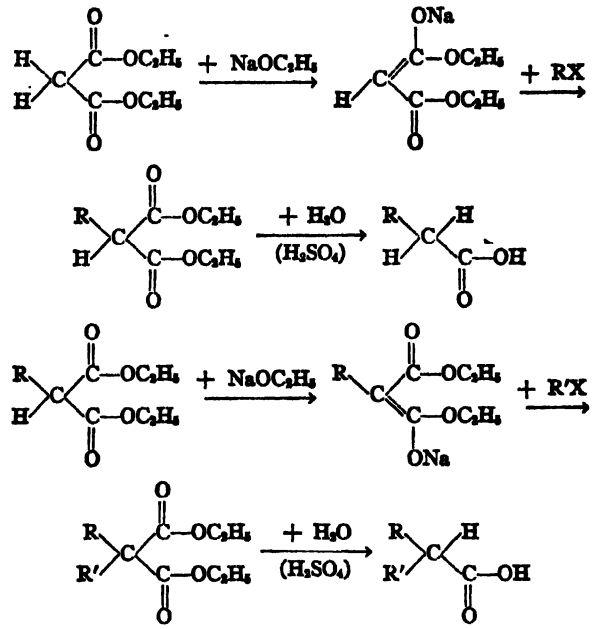
Also to be included in this category are various types of cyclization reactions of which the Wurtz-Fittig reaction of pentamethylene bromide to form cyclopentane and the acid-catalyzed cyclizations of derivatives of 2-benzyl-1-naphthoic acid to form derivatives of 1,2-benzanthrone may serve as illustrations:

$$Br(CH_2)_5Br + 2Na \rightarrow (CH_2)_5 + 2NaBr;$$

Conversely, many decyclization reactions are known; among the simplest are the opening of the cyclopropane ring by reaction with a halogen or a halogen acid:

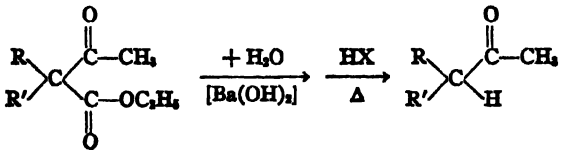
$$(CH_2)_3 + Br_2 \rightarrow Br(CH_2)_3Br;$$
$$(CH_2)_3 + HBr \rightarrow CH_3CH_2CH_2Br$$

Class 3. Augmentation of the Original Carbon Skeleton. —New carbon-to-carbon linkages may be established in a variety of ways. In some cases the Wurtz-Fittig reaction, the interaction of an organic halide (or halides) with a reactive metal like sodium (Na) or zinc (Zn), is applicable:



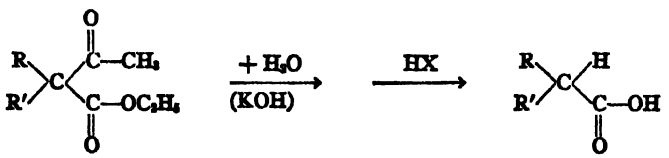
$$2RI + 2Na \rightarrow RR + 2NaI;$$
$$ArX + AlkX + Zn \rightarrow ArAlk + ZnX_2$$

The Grignard reagents (*q.v.*) (or organomagnesium halides) react with some alkyl and aralkyl halides, and with a variety of other types of organic compounds with the establishment of new carbon-to-carbon linkages. Several examples were cited at the beginning of this section.

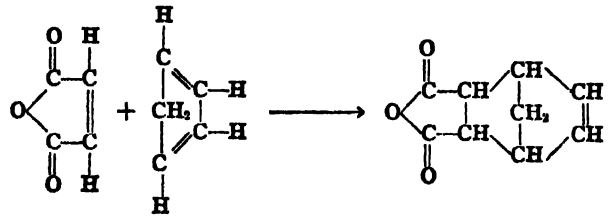


The Friedel-Crafts reactions and some of the carbonyl condensations have also been illustrated previously in this discussion.

Among the numerous other methods of establishing carbon-to-carbon linkages are: the malonic ester syntheses, the acetoacetic ester syntheses and the Diels-Alder condensations.



The malonic ester syntheses are essentially methods for the production of substituted acetic acids of the types RCH_2CO_2H and $RR'CHCO_2H$.



The somewhat similar acetoacetic ester syntheses may also be used to produce substituted acetic acids of the types RCH_2CO_2H and $RR'CHCO_2H$, on the one hand, or methyl ketones of the types CH_3COCH_2R or $CH_3COCHRR'$, on the other, depending upon the method of hydrolysis adopted as the final step in the process. Mild alkaline hydrolysis, followed by acidification and heating, yields a ketone.

Hydrolysis with strong, concentrated alkali, together with subsequent acidification, yields an acid.

The Diels-Alder reaction is another synthetic device of remarkable breadth of applicability. It consists of an additive reaction between one molecule containing a suitably activated carbon-to-carbon double bond and another molecule containing two conjugated carbon-to-carbon double bonds (C=C—C=C). Many such reactions take place spontaneously at room temperature. The reaction between maleic anhydride and cyclopentadiene may serve as an illustrative example.

So general is this reaction that maleic anhydride is often used as a specific test reagent for conjugated unsaturation in determinations of structure.

The numerous condensation, polymerization and copolymerization reactions resulting in plastics, synthetic resins and synthetic rubbers also fall into this class. Such products are of high molecular weight, and the reactions are by no means so simple and clear-cut as most of those previously discussed. However, the copolymerization of styrene ($C_6H_5CH{=}CH_2$) and butadiene ($CH_2{=}CHCH{=}CH_2$) to produce a synthetic rubber of the GR-S type may be represented in oversimplified fashion as follows:

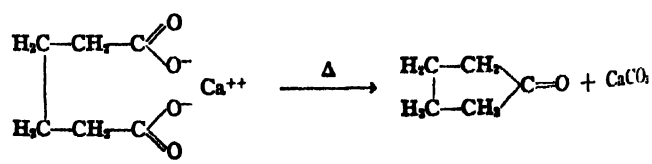
$$n\ C_6H_5CH{=}CH_2 + n\ CH_2{=}CH{-}CH{=}CH_2 \xrightarrow{(Cat.)} [{-}CH_2CH{=}CHCH_2CH(C_6H_5)CH_2{-}]_n$$

So many and so varied are the reactions of class three that the few examples cited can scarcely be said to constitute a representative sampling. They are, indeed, but a fraction of those with which every student of elementary organic chemistry is expected to acquaint himself.

Class 4. Degradations of the Carbon Skeleton.—All organic compounds, when heated to sufficiently high temperatures, undergo pyrolytic decomposition with cleavage of carbon-to-carbon bonds. In general, pyrolyses are of limited interest to theoretical organic chemists because many reactions occur simultaneously and give rise to mixtures of products. However, catalytically controlled pyrolysis is of great practical importance in the cracking of petroleum and has greatly increased the yields of gasoline obtainable from crude oils.

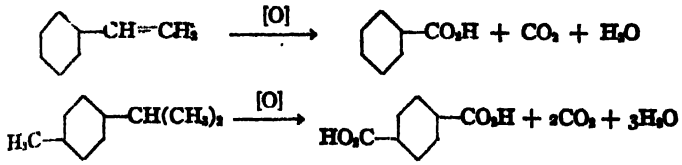
Some organic molecules are so constituted that moderate heating causes selective dissociation of a weak carbon-to-carbon bond (in some cases with the aid of catalysts, in others without). The more or less exceptional reactions of this kind are useful for preparational purposes. Among those most frequently employed are the decarboxylation reactions resulting in the loss of carbon dioxide from a carboxylic acid (RCO_2H).

Not all carboxylic acids are readily decarboxylated. Benzoic acid ($C_6H_5CO_2H$), for example, is so stable that thermal decomposition is accompanied by cleavage of the benzene ring. Examples of readily decarboxylated acids are to be found among the types having the following groupings: $>C(CO_2H)CO_2H$, $>COCO_2H$, $>C(NO_2)CO_2H$, $>C(OH)CO_2H$, $-CH(O)CHCO_2H$.



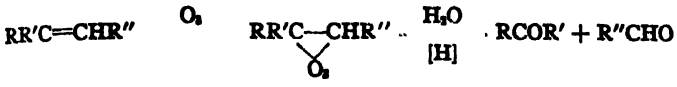
The substituted malonic acids belong to the first of these types, and the final stage of the malonic ester syntheses consists in a simultaneous hydrolysis and decarboxylation, usually effected by warming in the presence of aqueous sulphuric acid,

$$RR'C(CO_2C_2H_5)_2 \xrightarrow{H_2O} RR'C(CO_2H)_2 \xrightarrow[\Delta]{(H_2SO_4)} RR'CHCO_2H + CO_2$$



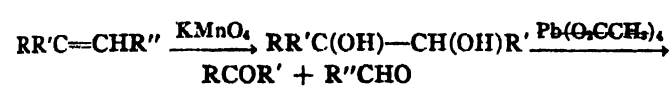
Many acids, which are too stable for ready decarboxylation as such, lose carbon dioxide when first converted to their salts and then heated. For example, trichloroacetic acid (CCl_3CO_2H) may be converted to chloroform ($CHCl_3$) and a carbon dioxide by heating in the presence of aniline ($C_6H_5NH_2$) with which it forms a salt,

$$CCl_3CO_2H \cdot H_2NC_6H_5 \xrightarrow{\Delta} CHCl_3 + CO_2 + C_6H_5NH_2$$

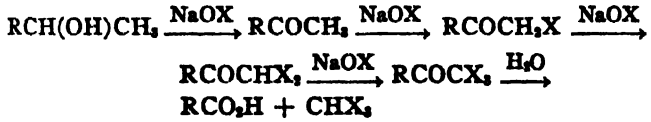


The synthesis of cyclic ketones has been effected in an analogous manner by heating the calcium salts of dicarboxylic acids.

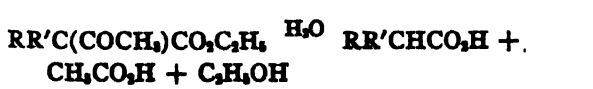
Organic chemists make use of a wide variety of oxidative degradations, both for preparational purposes and as a means of establishing the structures of compounds of unknown constitution. In general, it is possible to oxidize aliphatic side chains attached to aromatic nuclei to obtain the corresponding aromatic carboxylic acids. Thus, styrene may be oxidized to benzoic acid, and cymene to terephthalic acid.



Selective oxidative cleavages may be effected at definite points in a carbon chain if certain structural features are present. For example, oxidative cleavage of a double bond may be accomplished in several ways. One method frequently employed in elucidations of structure is by ozonization and subsequent hydrolysis of the resultant ozonide in the presence of a reducing agent. (The ozonide formula used in the illustrative equation is probably not a true indication of structure.)

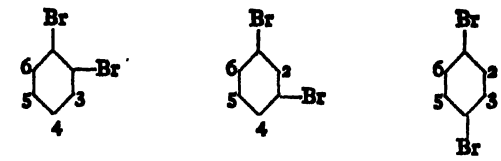


Identification of the resultant aldehydes, or ketones, or both, serves to establish the location of the double bond and to reveal the structure of the original olefin. In special cases, an olefin of known structure may be so treated as a means of preparation of aldehydes or ketones.



Adjacent carbon atoms bearing hydroxyl groups [$>CH(OH)-CH(OH)<$], either present as such or resulting from oxidative treatment of double bonds, may be dehydrogenated by mild oxidation, with cleavage of the carbon chain and production of carbonyl compounds (aldehydes or ketones),

The haloform (CHX_3) reactions may be used to effect oxidative hydrolytic cleavage at a $-CH(OH)CH_3$ or $-COCH_3$ grouping. Because iodoform (CHI_3) is a yellow crystalline solid of highly distinctive odour, the iodoform reaction is used as a specific test for the presence of such groupings:

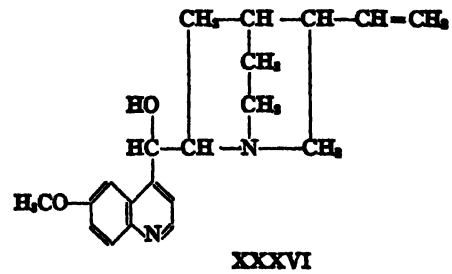


Although oxidative cleavages are those of greatest variety and widest applicability, hydrolytic cleavages are possible in a few special cases. The final stage of the acetoacetic ester synthesis as employed for the production of substituted acetic acids is an example:

SOME OBJECTIVES OF ORGANIC CHEMISTRY

Among the preoccupations of the organic chemist are the identification and determination of structure of natural and artificial compounds, the modification of natural compounds, the synthesis of natural compounds and the synthesis of artificial compounds for specific purposes.

The determination of the structure of a compound of unknown constitution is often a complicated task requiring the exercise of unusual ingenuity. However, one of the classical examples, Wilhelm Körner's "absolute method" for the identification of isomeric benzene derivatives (1874), is simple in principle. Prior to Körner's time, three dibromobenzenes were known. Granted the validity of Kekulé's benzene formula and the implied equivalency of the six carbon atoms and of the six carbon-to-carbon bonds of benzene, it was obvious that one isomer must be the ortho (1,2), one the meta (1,3) and one the para (1,4).

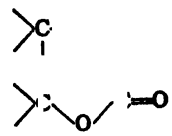


Ortho (1,2) Meta (1,3) Para (1,4)

Körner solved the problem of which was which by consideration of the geometry of the respective formulas. In ortho-dibromobenzene, the unsubstituted positions 3 and 6 are equivalent to each other, but different from positions 4 and 5, which are equivalent to each other. Hence, it should be possible to derive two isomeric tribromobenzenes (1,2,3 and 1,2,4) from 1,2-dibromobenzene. In meta-dibromobenzene, the unsubstituted positions 2 and 5 are unique, while positions 4 and 6 are equivalent to each other. Therefore, three isomeric tribromobenzenes (the 1,2,3, the 1,3,4 and the 1,3,5) are theoretically derivable from 1,3-dibromobenzene. In para-dibromobenzene, all the unsubstituted positions (2,3,5 and 6) are equivalent. Hence, but one tribromobenzene (1,2,4) is derivable from 1,4-dibromobenzene. The identical line of reasoning applies to the mononitrodibromobenzenes, with this difference, however, that, whereas there is a total of three isomeric tribromobenzenes, there are six nitrodibromobenzenes. Following this line of reasoning, though employing an indirect and somewhat more involved procedure than that implied, Körner prepared and identified the three isomeric dibromobenzenes, the three tribromobenzenes and five of the six nitrodibromobenzenes. Körner's method has been applied to the identification of many other benzene derivatives, although it sometimes presents considerable practical difficulties in the isolation of isomers produced in small amounts.

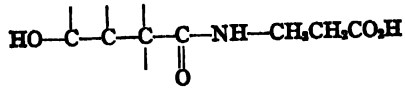
In general, however, the process is not so simple in principle, especially when relatively complicated substances of natural origin are involved. Although individual cases necessarily differ, a fairly representative structural determination might proceed substantially as follows. The molecular formula is derived by careful purification, accurate analysis and determination of molecular weight. Various functional groupings or structural features are identified by the application of specific tests or characteristic reactions. The substances may be subjected to various degradative processes in the hope that identifiable fragments may be isolated. When a satisfactory structural formula has been deduced, additional evidence of its validity may be supplied through synthesis of the compound by methods which leave little doubt of the structure of the product.

The elucidation of the structure of quinine (XXXVI) in 1908 when Paul Rabe proposed the correct formula for the closely



XXXVI

related cinchona alkaloid cinchonine, may be said to have followed substantially this pattern. It was not until 1944, however, that a total synthesis of quinine was achieved by R. B. Woodward and W. E. Doering through a long series of complicated reactions.



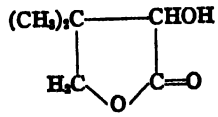
Another representative example, although one that presented unusual difficulties in the isolation and purification of minute quantities of compound from large quantities of starting material, was the determination of structure and the synthesis of pantothenic acid (XXXVII), one of the vitamins of the B complex, accomplished by two teams of research workers under the leadership of Roger J. Williams (1940). Although the complete details

of the elucidation of structure are rather technical and involved, the principal essentials may be outlined briefly as follows.

Natural pantothenic acid was not obtained in sufficient purity for reliable molecular-formula determination, but it was found that acid hydrolysis yielded β-alanine, a known amino acid ($^+H_3NCH_2CH_2CO_2^-$) and a neutral substance which formed a salt on further hydrolysis with alkali. These observations suggested that the neutral substance was a lactone, or inner ester, of a hydroxy acid, probably a γ-hydroxy acid. It would therefore contain the grouping

Pantothenic acid, therefore, probably contained a peptide (−CONH−) linkage, and included the grouping

Sufficient quantities of the supposed lactone were obtained for determination of its molecular formula as $C_6H_{10}O_3$. By the Zerewitinoff method (reaction with a methylmagnesium halide, CH_3MgX, to form methane, CH_4) it was determined that the molecule contained one active hydrogen atom, which suggested a hydroxyl (−OH) group other than the one involved in lactone ring-formation.



The hydrolyzed lactone (though not the lactone itself) gave with ferric chloride ($FeCl_3$) a colour test characteristic of α-hydroxy acids. Further confirmation of the presence of an α-hydroxy group was obtained through the reactions

$$RCH(OH)CO_2H \xrightarrow{H_2SO_4} RCHO + HCO_2H;$$

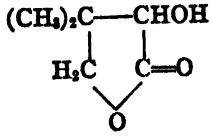
$$HCO_2H \xrightarrow[\Delta]{H_2SO_4} CO + H_2O;$$

$$RCH(OH)CO_2H + (CH_3CO)_2O \longrightarrow RCH(O_2CCH_3)CO_2H + CH_3CO_2H$$

In view of the molecular formula determined, and of the results of certain other diagnostic tests that cannot be detailed here, it appeared possible that the lactone had the constitution

and that pantothenic acid had the structure XXXVII.

$$HOCH_2C(CH_3)_2CH(OH)CONHCH_2CH_2CO_2H$$



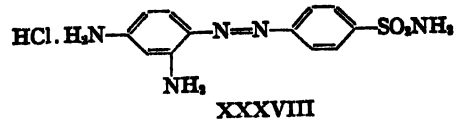
XXXVII

The confirmatory synthesis was relatively simple and easy.

$$HCHO + (CH_3)_2CHCHO \longrightarrow HOCH_2C(CH_3)_2CHO \xrightarrow{HCN}$$

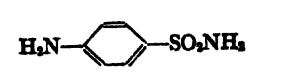
$$HOCH_2C(CH_3)_2CH(OH)CN \xrightarrow{H_2O}$$

$$[HOCH_2C(CH_3)_2CH(OH)CO_2H] \xrightarrow{-H_2O}$$



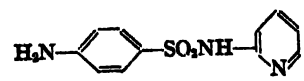
$$\xrightarrow{H_2NCH_2CH_2CO_2CH_2C_6H_5}$$

$$HOCH_2C(CH_3)_2CH(OH)CONHCH_2CH_2CO_2CH_2C_6H_5 \xrightarrow{H_2O}$$
$$HOCH_2C(CH_3)_2CH(OH)CONHCH_2CH_2CO_2H$$

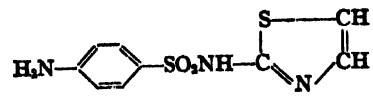


XXXVII

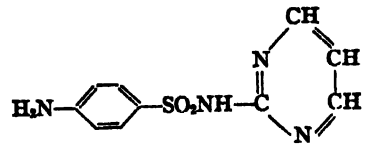
The synthesis of compounds for specific purposes is well illustrated by many examples in the field of organic medicinals. When it was discovered that the red dye, later known as Prontosil (XXXVIII), had bacteriostatic properties, chemists immediately



XXXVIII

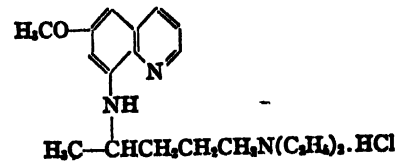


sought to discover the groupings responsible for its effectiveness, and soon found that the previously known sulfanilamide (XXXIX) had bacteriostatic properties similar to those of Prontosil itself. The race began immediately. The isomers of sulfanilamide were tested and found ineffective. Thousands of derivatives of sulfanilamide were prepared and investigated. Among the relatively few that were found to have properties superior in some respects to those of sulfanilamide were sulfapyridine (XL), sulfathiazole (XLI) and sulfadiazine (XLII).

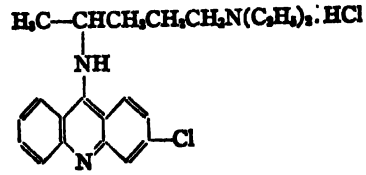


XXXIX

XL



XLI



XLII

The practice of taking a molecule of known properties as a model and attempting to synthesize compounds of similar or somewhat modified properties is illustrated by the synthetic antimalarials, of which Plasmochin (XLIII) and Atabrine (XLIV) may serve as examples. The structural relationship to quinine (XXXVI) is obvious.

XLIII

XLIV

The so-called synthetic rubbers are examples of a similar practice. The hydrocarbon of natural rubber is a high-molecular-weight polymer of isoprene [$H_2C{=}C(CH_3)CH{=}CH_2$] which may be represented in simplified fashion as [$-CH_2C(CH_3){=}CHCH_2-$]$_n$. However, the synthetic rubbers produced by the catalytic polymerization of isoprene are not duplicates of natural rubber and are inferior to it in several respects. A much closer approxima-

tion of some of the more desirable properties of natural rubber is achieved in the product of copolymerization of styrene and butadiene previously mentioned. A considerable variety of synthetic rubbers with special properties adapted to specialized uses have been produced. Some representative examples are indicated herewith:

$n\ H_2C{=}CClCH{=}CH_2 \longrightarrow [{-}CH_2CCl{=}CHCH_2{-}]_n$,
Neoprene GR-M;

$n\ H_2C{=}CClCH{=}CH_2 + n\ H_2C{=}C(CH_3)CH{=}CH_2 \longrightarrow$
$[{-}CH_2CCl{=}CHCH\ CH\ C(CH_3){=}CHCH_2{-}]_n$,
Neoprene FR;

$n\ H_2C{=}C(CH_3)CH{=}CH_2 + n\ (CH_3)_2C{=}CH_2 \longrightarrow$
$[{-}CH_2C(CH_3){=}CH_2C(CH_3)_2CH_2{-}]_n$, Butyl GR-I.

Another example of the synthesis of a compound to meet property specifications but without the attempt to duplicate any natural material is to be found in the synthetic fibre nylon. The process may be represented in simplified fashion as follows:

$$n\ HO_2C(CH_2)_4CO_2H + n\ H_2N(CH_2)_6NH_2 \longrightarrow$$
$$[{-}OC(CH_2)_4CONH(CH_2)_6NH{-}]_n + H_2O.$$

In a sense this fibre may be said to be patterned after the natural fibres silk and wool, for it contains the peptide (−OCNH−) linkages common to them, but it has distinctive properties and is by no means either a synthetic silk or synthetic wool.

One of the early successes of the dyestuff chemists was the production of synthetic indigo (1897), which quickly drove the natural product from the market. The modern dyestuff industry, however, is concerned almost exclusively with purely artificial materials carefully tailored to property specifications and nowhere duplicated in nature.

The foregoing examples properly may be said to deal largely with practical applications of organic chemistry, which are by no means the sole preoccupation of organic chemists. Nevertheless, they do serve to illustrate, however imperfectly and incompletely, some of the activities and thought processes of the organic chemist. In the final analysis, the distinction between pure and applied chemistry is one of motivation rather than of the intrinsic nature of the work. Many studies of prime theoretical significance have been made in the hope of ultimate practical application, whereas many discoveries of great practical importance have been the by-products of pure research.

PHYSICAL CHEMISTRY

The easiest definition of physical chemistry is that which describes it as the border-line subject between physics and chemistry, but this definition is not necessarily the most accurate. No greater clarity results by adopting the name "chemical physics." In fact, physical chemistry, since the first issue of the *Zeitschrift für physikalische Chemie* appeared in 1887, can claim to be a science in its own right. It certainly covers the ill-defined territory between physics and chemistry, as biochemistry does between chemistry and biology, and mathematical physics between mathematics and physics, but it can also stake a claim to quite a sizeable piece of land, as extensive and as cultivated as the regions conventionally allocated to the so-called pure sciences of physics and chemistry. We shall not here attempt a definition of physical chemistry, because, properly regarded, it is less a circumscription of subject matter than a method of approach, applicable equally to the problems of physics, chemistry, and biology. There can be no harm, however, in attempting to describe the physical chemist: he is a man who observes natural phenomena and records his observations, but maintains a judicious balance between the material changes themselves, the physical effects which accompany them and the mathematical machinery by means of which the whole can be most compactly condensed.

The three ordinary states of matter—solid, liquid and gaseous—fall within the province of physical chemistry, as do the metallic state, the interfacial state, the colloidal state, and, most important of all, the dissolved state of matter. The influence of heat, light and mechanical and electrical forces on the various states of matter forms the subjects of thermochemistry, photochemistry, piezochemistry and electrochemistry, which rank among the most important subdivisions of physical chemistry. A continuous treatment of these topics is to be found in textbooks, a selected list of which is appended. In this article various problems are discussed which, particularly during the 20th century, have been solved or are still being investigated in physical chemistry.

Adsorption.—When ethylene gas at atmospheric pressure is sealed in a vessel containing copper turnings, the pressure within the vessel gradually diminishes until it reaches a constant value. Similarly, when a solution of iodine is kept in contact with charcoal, the concentration of iodine diminishes until it reaches a constant value. Gas molecules in the first case and solute molecules in the second case have adhered to the surface of the solid. The phenomenon is known as adsorption, and occurs in varying degrees for all solutes and all gases kept over the surface of solids. Argon gas, for example, is adsorbed on the surface of potassium chloride crystals, and enzymes (*q.v.*) are adsorbed on kieselguhr. The extent of adsorption depends on specific properties of the adsorbed and the adsorbing molecules, on the temperature and on the concentration or pressure. The familiar facts have been utilized practically without being understood theoretically. The fairly general adsorbing power of charcoal, for example, explains its use in decolorizing solutions in the course of organic preparations, in protection against toxic vapours and in the treatment of digestive ailments. The reverse process, desorption, has been utilized in the isolation of pure enzymes. In an attempt to understand the mechanism of adsorption, many empirical relations appeared connecting the amount adsorbed with the principal variables, temperature and concentration. Curves showing the fractional adsorption as a function of the concentration at constant temperature are termed adsorption isotherms, and the empirical formulas advanced to account for these were numerous but unenlightening.

In 1916, Irving Langmuir (*q.v.*) proposed a theory of adsorption which was not only sufficient to explain the phenomena, but had extensive applications in other fields, which include statistical physics. His theory was simple. The surface of the solid, of area O cm.², is likened to a chess board, on which solute or gas molecules impinge. Some adhere to the unitary areas; others fly back to the bulk of the solution or the gas phase. When equilibrium is attained, a certain fraction, θ_s, of the area of the solid remains covered with adsorbed molecules. The fraction of free surface is then $(1-\theta_s)$. In deriving the theoretical expression for the adsorption isotherm, we shall use the terminology of solutions, though the formulas are applicable, *mutatis mutandis*, to gaseous systems. Let the total number of sites per unit area of surface, on which solute molecules can be adsorbed, be n_o, and the probability per second that an adsorbed molecule may become desorbed be ν_s. Then the total number of molecules escaping per second from a surface of area, O cm², is $On_o\nu_s\theta_s$. The total number of solute molecules reaching the surface from the solution in one second is proportional to the surface area, O, and to the concentration, n_s, of solute molecules. Denoting the proportionality factor by k_s, the number is thus k_sOn_s molecules per second. But only those which hit vacant sites are adsorbed. Hence the rate, of absorption is $k_sOn_s(1-\theta_s)$. At equilibrium, the rates of adsorption and desorption are equal. On solving for θ_s we find that $\theta_s = k_sn_s/(k_sn_s+\nu_sn_o)$, which is Langmuir's adsorption isotherm. From the form of this equation, we note that, at low concentrations, the fraction of the surface that is covered is proportional to the concentration of the supernatant solution, and is, in fact, $(k_s/\nu_sn_o)n_s$. At high concen-

trations, θ_s tends toward unity. The whole surface is then covered with adsorbed molecules, and the extent of adsorption becomes independent of the concentration. It is generally possible, by quite simple experiments, to measure the concentration, n_s^*, which corresponds to a surface which is only one-half covered. This concentration, from the isotherm equation, is seen to be $\nu_s n_o/k_s$.

Among the many recent applications of Langmuir's theory is the experimental determination of the number of catalytically active sites on the surface of a single enzyme. We have seen that $n_o = k_s n_s^*/\nu_s$. The proportionality factor, k_s, is given by classical theory in terms of the mass, m, of the solute molecule, the absolute temperature, T, and Ludwig Boltzmann's constant, k, which is numerically 1.372×10^{-16} erg/degree: $k_s = (kT/2\pi m)^{\frac{1}{2}}$. The probability per second, ν_s, that an adsorbed molecule will escape is given by quantal theory in terms of the energy, E, of adsorption, and Max Planck's constant, h, which is numerically 6.551×10^{-27} erg-second: $\nu_s = (kT/h)e^{-E/kT}$. We thus have $n_o = hn_s^*(2\pi mkT)^{-\frac{1}{2}}e^{-E/kT}$. The application of this formula to experimental results on the inversion of cane sugar by saccharase shows that there are only a few active sites, probably eight, on the not inconsiderable surface of one enzyme.

Systems of greater complexity and interest are those in which the surface can simultaneously adsorb more than one kind of solute. Let us denote the second solute by the subscript, I. The fraction of the surface which, under equilibrium conditions, is covered by solute molecules of the first type is now $\theta_s = k_s n_s / [k_s n_s + \nu_s n_o + k_I n_I (\nu_s/\nu_I)]$. This formula, as Langmuir has shown, can explain a number of the idiosyncrasies of catalyzed reactions in solution. Inhibition of chemical reactions and the poisoning of catalysts by substances such as mercuric chloride are readily understood as a preferential adsorption of these compounds and a consequent exclusion of the reactants from the active centres. Similarly, many reactions proceed at rates which are inversely proportional to the concentration of products. These were discovered by Emil Schuetz in 1900, and include the digestion of proteins; they indicate that the greater the extent of reaction, the smaller the rate of the persisting reaction. Clearly, in such cases, the products are more firmly adsorbed than the reactants. There can be little doubt that the sensation of satiety finds its mechanistic basis here; so also does the protective effect so often exerted by the products of hydrolysis on the enzyme responsible for their appearance.

The energy which an adsorbed molecule must acquire before it can become dislodged must, in general, depend on how many of its neighbouring sites are occupied. The experimental dependence of the heat of adsorption on the extent of adsorption was established experimentally by J. K. Roberts a few years before his untimely death during World War II. It ranks as the greatest single extension of Langmuir's theory, and is proving to be one of the most fruitful fields for the investigation of surface catalysis. The discovery has had far-reaching applications in theoretical physics, which, in attempting to derive statistical laws for condensed systems, had previously been at a loss to know how to make allowance for the dependence of the molecular energy on the probability of occupation of neighbouring sites.

Diffusion.—The sugar at the bottom of a cup of tea does not take long to dissolve into a syrup, but, if it were not stirred, it would take a very long time to distribute itself throughout the whole volume of the beverage. The process whereby a quiescent solute at a high concentration moves isothermally to a region of low concentration is known as diffusion. It is analogous to thermal conduction and viscous flow, and differs from them only in that matter is transported in diffusion, whereas energy and momentum, respectively, are transported in the others. The exact mathematical theory of all three phenomena is difficult, but new laws of great beauty and simplicity have, nevertheless, been discovered by Albert Einstein during the first decade of the 20th century, and have had much to do with elucidating the nature of diffusion. They have been applied to determine the Avogadro number; *i.e.*, the number of molecules in one gram-molecule, to estimate the size of colloid particles, to evaluate the time taken by a given molecule in the gas phase or in solution to reach the walls of its container, and to develop the modern theory of liquids.

The number, dN, of molecules transported in a time interval, dt, across an area, O, is, according to Adolph Fick's law, proportional to both dt and O, and to the concentration gradient, dn/dx, at the plane crossed: $dN = -DO(dn/dx)dt$. The proportionality factor, D, is termed the coefficient of diffusion. Molecules are transported in the direction of increasing x only when the concentration gradient in that direction is negative. By subtracting from dN_1, the number of molecules crossing a given plane, the number dN_2, crossing a neighbouring and parallel plane at a distance, dx, from it, we obtain the net transport. Since dN/Odx is the increase in concentration between the planes, it may be denoted by dn, so that $dn/dt = D(d^2n/dx^2)$, which is a more general expression for the coefficient, D, of diffusion. When molecules at a concentration, n, move with an average velocity, v, the number which in one second cross unit area of a plane at right angles to the direction of motion is nv. The rate of transport of molecules across an area O cm.^{2} is thus $dN/dt = Onv$. Comparison with Fick's law indicates that the coefficient of diffusion is $D = -nv/(dn/dx)$. According to J. H. van't Hoff's laws, the osmotic pressure, π, of a solution containing n molecules per cubic centimetre is $\pi = kTn$. Any isothermal change in the osmotic pressure must therefore be the result of a change in the concentration, so that $d\pi = kTdn$. The additional force exerted in the direction of increasing x on an area, O, caused by a difference in concentration is thus $-Od\pi = -OkTdn$. The number of molecules exerting the force is the number contained in the volume element, Odx, which is $nOdx$. Hence the force exerted by each molecule is, on an average, $X = -(kT/n)(dn/dx)$. The uniform velocity, v, is the ratio of this force to the resistance factor, s. Thus $v = X/s$. Sir George G. Stokes's expression for the resistance factor in the case of a spherical molecule of radius, r, moving in a medium of viscosity, η, is $6\pi\eta r$. Hence $vn/(dn/dx) = -kT/6\pi\eta$. According to our previous equation, the expression on the left side is simply the coefficient of diffusion with the sign reversed. It follows that $D = kT/6\pi\eta r$, which is Einstein's equation. The coefficients of diffusion and viscosity are not difficult to measure at a constant temperature, T, and the radii of particles diffusing in solution thus become directly measurable.

We have hitherto regarded diffusion as a property of molecules in systems of uneven concentration, and as the mechanism whereby uniformity of concentration is established. The process, however, must persist, though without a net transfer of matter, even in systems of uniform molecular concentration. We can, for example, apply the laws of diffusion to determine the fate of an arbitrarily selected group of molecules from one part of an equilibrated system to another. By solving the differential form of Fick's equation in the case of linear motion, it can readily be shown that the uniform velocity at the distance x is $v = D/x$. But $v = dx/dt$; hence $dx/dt = D/x$, which gives on integration: $x^2/2 = Dt +$ a constant. We choose the system of reference for the selected migrating molecules as that corresponding to $x = 0$ when $t = 0$, so that the square of the net displacement suffered by the selected molecules in time t, and measured along the x axis, is $x^2 = 2Dt$, which is the second of Einstein's diffusion laws. It has been verified by Jean Perrin in a series of well-known experiments, using colloidal particles, made visible in the ultramicroscope, and followed at time intervals of a few seconds. It is to be noted that, because the motion is a random one, the average distance traversed (or, more precisely, the square root of the average of the square of the distance) is proportional, not to the time, but to the square root of the time.

Einstein's treatment of diffusion has done much to stimulate work in the physical chemistry of solutions. In particular, attempts have been made to extend the treatment to the movement of molecules under the influences of forces other than the thermal and viscous forces to which the early work has been restricted. Only partial success has been achieved, in cases where the additional force is of a simple and well-known form. There is, however, no reason why the method should not ultimately prove

helpful in the recognition of the type of force actually at work.

Perrin's experimental verification of Einstein's second law of diffusion has afforded one of the most accurate estimates of the Avogadro number. It is 6.063×10^{23} molecules per gram-mole. This fundamentally important constant has also been measured, with confirmatory results, in many other ways. It enables the physical chemists to compute, in all systems of interest, the actual number of molecules present. One drop of water, weighing five milligrams, is thus found to contain 168.3 million million million molecules.

Coagulation.—Colloid particles may be prepared, either in the gaseous phase or in solution, by a variety of methods. Aerosols, for example, may be made by mixing the vapour of the substance to be dispersed with a blast of air at a lower temperature, or by suddenly bursting a sample of liquid at great pressure into air at ordinary pressure. Collosols may be made by slow chemical reaction in dilute solution or, in the case of metals, by G. Bredig's method of sparking between electrodes immersed in the solvent. The chief characteristic of the dispersed phase in either system is its instability. The dispersed particles, when initially generated, are relatively small, but, with the passage of time, they become coarser, until they are large enough to come under the influence of gravity. The process of coarsening is termed coagulation, and it has been extensively studied. Experiment shows that the instantaneous rate at which the number of particles diminishes is proportional to the square of the concentration, n, of particles present at that instant. We may then write $-dn/dt=k_2n^2$, where k_2 is the coefficient of coagulation. On integrating—and noting that the initial condition of $t=0$ corresponds to the initial concentration of $n=n_0$—we have $k_2=(1/t)\times(1/n-1/n_0)$. If we denote by $t_{\frac{1}{2}}$ the time required for the number of particles to be reduced to one-half of their original number, then clearly $k_2=1/t_{\frac{1}{2}}n_0$. These formulas are characteristic of bimolecular processes. The latter simply states that the product of the half life and the initial concentration for such processes is a constant, and that it is equal to the reciprocal of the bimolecular velocity coefficient. They have been abundantly verified for the process of coagulation in solution and in the gaseous phase. On rearranging the latter equation, in logarithmic form, we have $\log_{10}t_{\frac{1}{2}}=-\log_{10}k_2-\log_{10}n_0$. A plot of the logarithm of the half life against the logarithm of the initial concentration should thus be a linear one, with a gradient of -1, and it should intercept the abscissa at a concentration numerically equal to the reciprocal of the bimolecular velocity coefficient. These generalities are illustrated in fig. 1, which has been drawn from P. Tuorila's data on the rate of coagulation of colloidal gold in water at 20° C. It will be noted that the initial concentration has been varied by a factor of more than 10,000, and that k_2 becomes 0.8×10^{-12} c.c./particle-second, which has a constant value over the whole range of concentrations. There can be no doubt that the coagulation of sols in aqueous solution takes place, as R. Zsigmondy first showed, as a result of binary encounters.

We next inquire, following M. von Smoluchowski, into the theoretical interpretation of the coefficient, k_2, and for this purpose must determine the frequency of binary collisions. The number of molecules of type A which, in one second, cross a spherical surface of radius, r, surrounding a molecule of type B is the product of the concentration of the A molecules by their velocity and by the spherical area. We have seen that the velocity is D/r, and, since the area is $4\pi r^2$, the number crossing per second is $4\pi Drn_A$. This equals the number of collisions, when r becomes the sum of the radii (r_A+r_B) of the colliding partners. Hence ${}_1Z_A=4\pi D(r_A+r_B)n_A$. The total number, ${}_AZ_B$, of collisions in unit volume is n_B times as great. Viewing the problem from the complementary angle of a stationary A molecule surrounded by approaching B molecules, and taking the mean, we obtain, for the number of binary collisions in unit volume and in unit time: ${}_AZ_B=2\pi(D_A+D_B)(r_A+r_B)n_An_B$. On making use of Einstein's first diffusion formula, we may rewrite this expression in terms of the viscosity, obtaining ${}_AZ_B=(kT/3\eta)(r_A+r_B)^3n_An_B/r_Ar_B$, which, for particles of equal radii, reduces to $(4kT/3\eta)n^2$. Now if a collision between two particles is a sufficient condition for their coalescence, the coagulation coefficient, k_2, should equal $4kT/3\eta$. The viscosity of water at 20° C. being 0.01005 gram/cm.-second, the theoretical estimate of k_2 is seen to be 5.33×10^{-12} c.c. per particle-second, which is in good agreement with the experimental findings of Zsigmondy and of Tuorila. Moreover, the temperature dependence of the bimolecular velocity constant is correctly reflected by the ratio T/η. Smoluchowski's theory thus provides a fairly complete account of the kinetics of coagulation in solution, and establishes the fact that the rate of this process is simply the rate at which particles collide with one another. Points of refinement deal with the uneven distribution of particle size, and are relatively unimportant. There is also the possibility of preferential dissolution from the surface of the smaller particles.

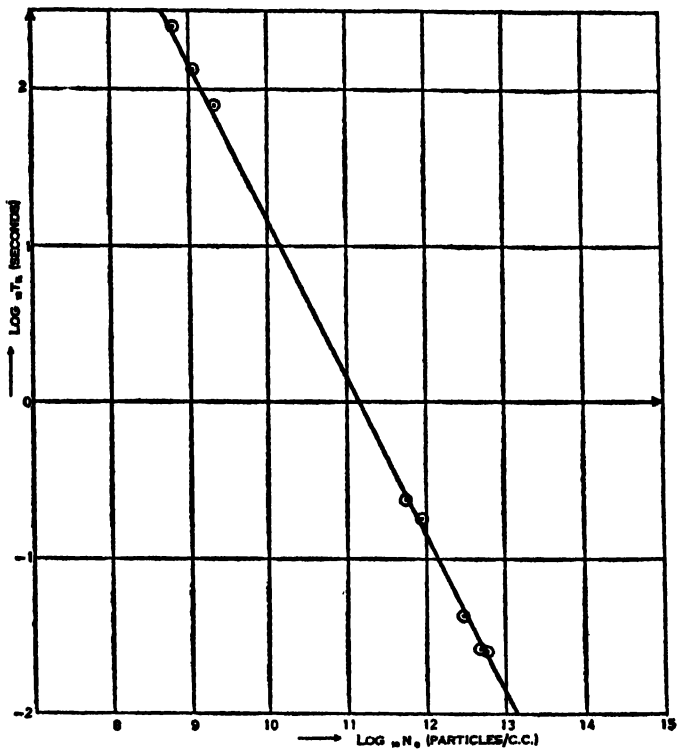

FIG. 1.—THE BIMOLECULARITY OF THE COAGULATION OF COLLOIDAL GOLD

Air at 20° C. is about 55 times less viscous than water at the same temperature. If, therefore, colloidal particles in air coagulate according to the same mechanism as colloidal particles in solution, the coagulation coefficient should be greater by about this factor, and should therefore be about 3×10^{-10} c.c. per particle-second. Smokes made from a variety of substances, such as magnesium oxide, cadmium oxide, long-chain fatty acids and resinous materials, have been examined by R. Whytlaw-Gray and H. S. Patterson, who find that k_2, though not exactly 3×10^{-10}, seldom varies beyond the limits of 5 and 8 in the same units. Vaporization from the particulate surface and the possible inadequacy of Stokes's expression for the frictional resistance factor are among the explanations offered for the slight discrepancy. Apart from points of detail, however, Smoluchowski's theory is as applicable to aerosols as to collosols. The point is an important one, as the work in the two phases has been carried out by different investigators, in different countries, and without liaison or much knowledge of one another's activities. It is, perhaps, one of the most attractive features of 20th century physical chemistry that theories, like that of Smoluchowski, sometimes emerge which, on being extensively applied, bring coherence to sets of phenomena which have been traditionally regarded as unrelated.

The Quenching of Resonance Radiation.—A substance that, while absorbing radiation of a given wave length, simultaneously emits radiation of a longer wave length, is said to fluoresce. Aqueous solutions of chlorophyll, fluorescein, disodiumuranine

and quinine bisulphate are familiar examples. The phenomenon of fluorescence was interpreted at the end of the last century in terms of ionization, but not until the advent of the quantum theory was the correct interpretation provided, by O. Stern and M. Volmer and by O. Klein and S. Rosseland, who postulated the theory that electronically excited molecules or ions could loose their electronic energy either by spontaneous emission of radiation, as envisaged by Einstein in his theory of the distribution of thermal radiation, or in radiationless transfers of energy during collision. The theory has been amply verified for the quenching of resonance radiation of thallium, mercury, sodium and cadmium atoms in the gas phase by Guenther Cario and J. Franck, and for the quenching of the fluorescence of numerous solutes in aqueous solution by S. J. Wawilow and by R. H. Mueller, E. R. Jette and W. West. Jean Perrin, E. Gaviola and others have employed the theory to determine the average lifetime of electronically excited structures. The theory can best be formulated in terms of a general procedure, devised by J. A. Christiansen and H. A. Kramers, and generally referred to as the stationary state procedure.

It is assumed that the electronically excited molecules are produced at a rate which is proportional to the concentration of normal molecules, say, n_A per c.c. The rate of production may then be given as $k_3 n_A$, where the proportionality constant, k_3, depends in magnitude on the nature and intensity of the exciting radiation and on the dimensions and design of the reaction vessel. A three-fold fate awaits these excited structures. They may, in the first place, emit radiation spontaneously, at a rate which is proportional to the concentration, a, of the excited structures. Let this rate of emission be denoted by $k_1 a$, where k_1 is the decay constant, or the reciprocal of the mean life. They may, in the second place, be robbed of energy in collisions with normal molecules of their own kind: this rate is a bimolecular one, and may be denoted by $k_4 n_A a$. Finally, the excited molecules, atoms or ions may loose energy by transfer during collisions with molecules of another kind, which, let it be supposed, are present at a concentration n_B molecules per c.c.: this rate again is a bimolecular one, and may be expressed as $k_2 n_A a$. When a stationary concentration of excited molecules has been reached, the rate of production by absorption of light equals the sum of the three rates of destruction. We can thus solve for a, the concentration of excited molecules. But the rate of emission is known to be $k_1 a$. Eliminating a from these two expressions, the rate, I, of emission is seen to be $k_1 k_3 n_A/(k_1+k_2 n_B+k_4 n_A)$. Maximum emission, I_0, coincides with absence of the quenching molecules, and is clearly $k_1 k_3 n_A/(k_1+k_4 n_A)$. The ratio of the intensity of fluorescence in the absence of a quenching material to that in the presence of a quencher is $I_0/I = 1+\frac{(k_2)}{(k_1+k_4 n_A)} n_B$. If self-quenching is insignificant, the term $k_4 n_A$ can be ignored; the ratio I_0/I is then a linear function of the concentration of quenching molecules, and the gradient $d(I_0/I)/dn_B$ is the ratio of two velocity coefficients, k_2/k_1. The decay constant, k_1, is known from other sources, and the velocity coefficient governing the bimolecular process whereby excited molecules are deprived of their energy can thus be determined. When its magnitude is compared with the number of collisions, as given by the formula in the section on coagulation, we find varying results, according to the quenching molecule. Collisions between the quinine ion, electronically excited, and the normal iodide ion in water almost invariably lead to a radiationless transfer of energy. Collisions of the same organic ions with other inorganic quenchers are never quite so efficient. Inorganic ions, in fact, range themselves in an order of quenching efficiency that is the same as the order of electronic polarizability, coagulation power and lyophilic activity. The constant k_2 for gaseous processes, such as the damping of resonance radiation of sodium atoms by nitrogen molecules, is usually greater than the number of collisions occurring per c.c. per second. This result has generally been interpreted as indicating that the electronically excited atom has a larger radius than the normal atom. Certainly, if we apply to the experimental results the formulas of the kinetic theory of gases, we must employ a radius of capture which is considerably greater than the radius as measured by other means; but this explanation cannot be ultimately satisfactory, and the problem in the meantime is largely unsolved.

Perhaps ... attaching to recent work on the quenching of resonance radiation in gases and of fluorescence in solution is that it brings to the fore the mechanism according to which, during collisions, energy of one kind is converted into energy of another kind. The present examples are confined to the conversion of electronic energy into some other form; *e.g.*, into kinetic energy, but the problem posed is a much more general one. When, for example, an atom of argon collides with a molecule of nitrogen, does the kinetic energy of the atom become exchanged for the kinetic energy of the molecule? Or does the atom during collision transmit its energy into vibrational energy of the molecule? In principle, these are questions which the quantum theory is able to answer but, in practice, little has yet been done in deriving the mathematical solution. A difficulty in the way is that one must possess complete information of the forces at work, and this is not always available. Assumptions as to the form of forces acting at short distances have been made, for example, by C. Zener, who has consequently arrived at a partial solution of the problem of conversion of energy from the kinetic to the vibrational kind. Arnold Eucken and his collaborators have pursued the same problem experimentally, using acoustical methods. The limit of accumulation of vibrational energy in a diatomic molecule corresponds to its dissociation into atoms, a process which is known to happen in certain cases of resonance quenching. Moreover, the most efficient quenchers are diatomic molecules whose energy of dissociation lies near to the quantum of energy emitted by the electronically excited atom. The theory of energy transfer during collisions is, as yet, in its infancy, and many more experimental guides such as those enumerated here will probably have to be discovered before any considerable growth can ensue.

Spectroscopy.—Studies made after 1930 of the radiation absorbed and emitted by chemical compounds in the gaseous and dissolved states of matter have given the physical chemist a more penetrating insight into the structure of molecules than would have been thought possible at the beginning of the 20th century. The key to the interpretation of the multitudinous spectra exhibited was provided by Ernest Rutherford and Niels Bohr in their treatment of the spectrum of the hydrogen atom. According to their well-known theory, the hydrogen atom can exist only in definite energy states; all conceivable energy states lying between these so-called "quantized" states are excluded from the realm of possibility. The energy levels are related to one another in the ratio of the inverse square of the integral ordinal numbers. To adopt an analogy effectively used by Bertrand Russell, it is as if the citizens of some fictitious town were allowed to possess curious sums of money, such as £100, £25, £11–2–2¾, but not sums intermediate between these. All transactions would then be in terms of equally curious sums, such as £75, £13–17–9¼, but not in intervening quantities. Analysis of the spectra of molecules shows that molecular electronic levels resemble atomic electronic levels. Vibrational energies in molecules are, however, almost directly proportional to integral ordinal numbers, and rotational energies are approximately proportional to the squares of integral numbers. Excluding the translational energy, the total energy of molecules may be considered as made up of three components, viz., the electronic energy, E_e, the vibrational energy, E_v, and the rotational energy, E_r. *Then* $E=E_e+E_v+E_r$. The difference between two neighbouring electronic energy levels in molecules is usually commensurable with the difference in the electronic levels in atoms. For every electronic energy level, there exists a number of vibrational levels, which lie relatively near to one another. Associated, in turn, with each vibrational energy level are many rotational levels, which, generally, lie still nearer together. The rotational energy, E_r, of a molecule in any given state depends not only on the rotational quantum number, J, but also on the vibrational quantum number, v, as well as on the electronic quantum number necessary to define completely a given molecu-

lar state. The vibrational level is also to some extent dependent on E_e, but the latter is independent of either J or v. The transition of a molecule from a state with energy E to one with a higher energy, E^1, is accompanied by the absorption of a quantum of radiation, $h\nu$, where h is Planck's constant, and ν is the frequency of the radiation absorbed. $\nu=(E^1-E)h$ $=\frac{E^1_e+E^1_v+E^1_r}{h}$

$$-\frac{E_e+E_v+E_r}{h}-\frac{E^1e-E}{h}+\frac{E^1_v-E_v}{h}+\frac{E^1_r-E_r}{h}=\nu_e+\nu_v+\nu_r.$$

When both ν_e and ν_v are zero, all the absorption lines in the spectrum are the result of transitions between two states of the molecule with fixed electronic and vibrational quantum numbers; the lines of absorption are said to constitute a pure rotation band, and, since they occur between energy levels which lie very close together, the frequencies of the absorbed radiation are low, and therefore the wave lengths of the absorption lines are large. They are found in the infra-red region of the spectrum. When only $\nu_r=0$, the lines may be caused by transitions between molecular states differing in both their vibrational and rotational quantum numbers; the lines constitute vibration-rotation bands, and often appear in the visible region of the spectrum. When ν_e, ν_v and ν_r have all positive values, the lines of absorption or emission correspond to transitions between molecules which have different electronic, vibrational and rotational energies. The whole band system may then extend right across from the far infra-red to the far ultra-violet regions. On account of the inequality $\nu_r > \nu_v > \nu_r$, it follows that the general position of a nonelectronic band is governed by the vibrational quantum number, while the structure of the various bands is determined by the rotational quantum numbers.

Special apparatuses and techniques pertain to the various spectra, and, although many physical chemists within recent years have devoted their time to the investigation of molecular spectra, the subject is so vast and the experimental intricacies attached to the various spectral regions so specific, that few investigators, if any, can claim to be directly acquainted with more than one technique. Experimentally, the investigators are grouped as infra-red, visible region and ultra-violet spectroscopists, and, as we shall see in the next section, as Raman spectroscopists. With the details of the investigations we are not here concerned. It is, however, necessary to outline the theoretical sections of the quantum theory which have been advanced by spectroscopic knowledge and to indicate briefly what information of value to the physical chemist has emerged in very simple cases.

According to the quantum theory, the rotational energy of a diatomic molecule, with a moment of inertia, I, is $E_r=J(J+1)\times\frac{h^2}{8\pi^2 I}$ where $J=0, 1, 2, 3 \ldots$ The difference in energy between two neighbouring states is thus $J(J+1)(h^2/4\pi^2 I)$. The greater the rotational quantum number, the farther apart are the energies of any two neighbouring states. The emission frequencies form given states to those immediately below them are, by the Bohr frequency law, $(J+1)(h/4\pi^2 I)$. Transitions between systems performing simple harmonic motions, of which free rotation is an example, can take place only with unit change in the quantum number. The frequencies of the radiation absorbed or emitted by diatomic molecules in the infra-red region of the spectrum should therefore be $\frac{h}{4\pi^2 I}$, $2\frac{h}{4\pi^2 I}$, $3\frac{h}{4\pi^2 I}$, etc. Except for a small correction, this conclusion has been verified in the case of the hydrogen halides. Karl Czerny found that the pure rotational frequencies (in reciprocal seconds) of hydrogen chloride and hydrogen bromide are, respectively, $6.034\times10^{11}\times M$ and $5.002\times10^{11}\times M$, where M is 1,2,3,4, ... Now the moment of inertia is the product of the reduced mass of the rotator and the square of the distance apart of the nuclei. In this way it is possible to determine accurately the internuclear distances in simple molecules. The results for hydrogen fluoride, hydrogen chloride, hydrogen bromide and hydrogen iodide are, in Angstrom units, 0.923, 1.281, 1.421, and 1.617 respectively. A more detailed analysis takes into account the fact that ordinary hydrogen chloride, for example, is a mixture of two kinds of molecules, one of which contains the chlorine atom of atomic weight 35, and the other the chlorine atom of atomic weight 37. The internuclear distance is found to be the same for the two molecules.

If the nuclei in a diatomic molecule were to vibrate harmonically with a frequency ν, the total vibrational energy of the molecule characterized by a quantum number, v, would be $E_v=(v+\frac{1}{2})h\nu$, and, by the Bohr frequency relationship, the frequency of the radiation absorbed or emitted would be $\nu_v=\nu$. But, since transitions between harmonically vibrating systems must coincide with unit changes in the quantum number, there should be only one absorption or emission line, and its frequency should be identical with the vibration frequency of the molecule. H. Deslandres has shown that the vibrational energy levels are more satisfactorily reproduced by the equation, $E_v=(v+\frac{1}{2})h\nu-x(v+\frac{1}{2})^2h\nu$, in which the empirical factor, x, though numerically small, is never zero. It can be shown to be approximately equal to $h\nu/4D$, where D is the energy necessary to dissociate the molecule into atoms. The analysis of the vibrational spectra of simple molecules thus yields information on two important properties—the frequency of internuclear vibration, and the energy of dissociation. The vibration frequencies of the halogen molecules, in units of 10^{12} reciprocal seconds, are thus found to be 16.03 (Cl_2), 9.712 (Br_2) and 6.424 (I_2). The dissociation energies of the alkali metal diatoms, expressed in units of kilocalories per gram-molecule are, by the same method, found to be 26.275 (Li_2), 17.515 (Na_2) and 11.800 (K_2) (*see* fig. 3).

The absorption or emission lines in the electronic spectra of simple molecules can be represented semiempirically by equations of the Ritz-Rydberg form, which include terms inversely dependent on the square of an integral number. The constant term in the formula affords an analytical means of estimating the limit of absorption of electronic energy, and thus of the energy required to eject the least firmly bound electron. Ionization potentials of simple molecules and electron affinities of simple ions thus come within the reach of experiment. Both are of fundamental importance in the description of the electronic structure of molecules, a subject that, from the purely theoretical aspect, is fraught with complications.

From these elementary beginnings, modern physicochemical spectroscopy bifurcates. One branch seeks, with only qualified success, to extend to more complicated molecules the dynamic principles on which the spectra of diatomic molecules have been interpreted. The more complicated the molecule, the greater is the number of electrons and nuclei contained in it, and the more numerous, for that reason, are the ionization potentials and the internuclear frequencies. The other branch is directed to the applications of the spectra to the problems of chemical analysis, and has progressed further. Spectroscopic methods are now familiar not only for detecting impurities in suspect samples but also for estimating the composition of mixtures, the ordinary physicochemical analysis of which is too difficult. The preparation of vitamins from fish oils and the rectification of high-grade aviation spirit from natural petroleum are but two of the important industrial spheres in which spectroscopic analyses have proved to be supreme.

The Raman Effect.—In absorption spectra, atoms and molecules assimilate only those quanta of radiation to which they are constitutionally adapted. In Raman absorption, incident light of an arbitrary frequency is used. Moreover, the experimental technique is relatively simple. Raman instruments now accordingly take their place among the most useful tools of the physicochemical workshop. The research laboratories of all progressive universities and industries can boast of a Raman spectroscope.

It has been known since John Tyndall's time that a faint blue colour becomes visible from all directions when a beam of white light is passed through a pure transparent medium. Light of short wave length is more readily scattered than light of long wave length, as Lord Rayleigh emphasized in his explanation of the blueness of the sky. When, instead of white light, a beam of monochromatic radiation is allowed to pass through a homogene-

ous specimen of matter, light detected in a direction perpendicular to that of the incident beam is found to contain, in addition to the original radiation, light of other frequencies, in numbers and intensities which depend on the scattering medium. The displaced lines, on analysis after resolution in the detecting spectroscope, are found to be much fainter than the line resulting from the original light; exposures of several days are often necessary for the measurement of their position and intensity. The scattering of homogeneous radiation by chemical compounds is termed the Raman effect (*q.v.*). It was experimentally established by Sir C. V. Raman and K. S. Krishnan, in 1928, though its occurrence had been theoretically foreshadowed by A. Smekal, in 1923. Since its discovery, tens of thousands of compounds have been investigated by its means, with important consequences.

Let us consider a head-on collision between a quantum, $h\nu_1$, of incident light and an atom or molecule of mass, m, which is supposed to be moving with velocity v_1, and to possess an internal energy, E_1, in addition to its kinetic energy, $\frac{1}{2}mv_1^2$. The energy of the incident photon is $h\nu_1$, and, according to an important quantal law discovered by Louis de Broglie, its momentum is $h\nu_1/c$, where c is the velocity of light. The laws of the conservation of energy and momentum then give us the relations $h\nu_1+E_1+\frac{1}{2}mv_1^2=h\nu_2+E_2+\frac{1}{2}mv_2^2$ and $(h\nu_1/c)+mv_1=(h\nu_2/c)+mv^2$. The maximum energy exchange clearly occurs when $v_1=0$, and $\nu_2=0$; *i.e.*, when the whole kinetic energy of the incident photon is completely converted into kinetic energy of the atom or molecule which was initially at rest. We have only considered head-on collisions, but it can be shown by classical dynamics that the conclusion is a true one in general. It follows that the maximum gain in kinetic energy is $\frac{1}{2}mv_2^2=\frac{1}{2m}(mv_2)^2=\frac{1}{2m}\left(\frac{h\nu_1}{c}\right)^2$.

Under the most favourable conditions, therefore, the fraction of the incident energy, $h\nu_1$, which is convertible is $h\nu_1/2mc^2$. This is of a very small order of magnitude. When, for example, the 4358Å line of the mercury spectrum is used as incident radiation, and carbon tetrachloride as the scattering medium, the fraction proves to be less than 10^{-11}. Any change in the frequency of the light caused by its passage through the medium must accordingly be the result of a change in the internal energy of the molecule. The first of Smekal's equations now becomes, effectively, $\nu_1-\nu_2=(E_2-E_1)/h$. The difference between the frequencies of the incident and emergent radiation is termed the Raman frequency: it could with more logic be termed the Raman shift. We have, then, the relation $\nu_R=\nu_1-\nu_2$ where ν_R can be greater than, equal to or less than zero, according as the light is displaced toward the red end of the spectrum, is unaffected, or is displaced toward the ultra-violet end of the spectrum. The responsible collisions are said to be, respectively, inelastic, elastic or superelastic. The extent of the displacement in the two directions is the same, so that lines in the scattered radiation appear in pairs, equidistantly draping the undisplaced line. The intensities of the two displaced lines are, however, very different, and, by measuring the way in which the ratio of the two intensities varies with respect to the temperature, it has been possible to ascribe a numerical value to Planck's constant, h.

Although the occurrence of the Raman effect becomes intelligible in terms of Smekal's hypothesis, its true origin is to be traced to the fact that, on account of the vibratory motion executed by the atoms within a molecule, the molecular polarizability varies with the phase of intramolecular motion. The interplay between the variable internal field thus set up and the harmonic field caused by the electrical component of light results in the generation of three electromagnetic vibrations, of frequencies ν_L, $\nu_L+\nu_R$ and $\nu_L-\nu_R$, where ν_L is the frequency of the incident light, and ν_R is the Raman frequency.

The commonest source of light used is that given by the mercury vapour discharge tube, which emits strong radiation of wave lengths 5460.74, 4358.34 and 4046.56 Ångstrom units. These correspond to the reversal of the electronically excited mercury atom from the $2s$ state to the three $2p$ states. Two of these radiations may be cut out by suitable filters (such as quinine sulphate to eject the 4047 line), and as intense a beam of the monochromatic 4358 line as possible is used to irradiate the medium—generally in the pure liquid phase. The total light emitted is recorded on a photographic plate after resolution through a prism.

Experiment shows that the Raman shift, *i.e.*, the difference between the frequencies (or wave-numbers) of the incident and scattered radiation, is (1) independent of the frequency of the incident light; and (2) to a first approximation, independent of the state of the scattering substance. By virtue of Smekal's equations, the quantum $h\nu_R$ equals the difference between two stationary energy levels of the scattering molecule. The Raman wave numbers, in reciprocal centimetres, of the chloride, bromide and iodide of hydrogen in the gaseous phase are, respectively, 2880, 2558 and 2233. Very often the evidence afforded by Raman spectroscopy is complementary to that given by infra-red absorption spectroscopy, as lines missing in one may appear in other. In the case of the three heteronuclear diatomic molecules mentioned here, the missing null lines in the infra-red spectra of the gases have the wave numbers 2887, 2559 and 2240, respectively. Experiments show that the Raman wave numbers of these three compounds in the liquid state are about 80 less, and in the solid state about 130 less, than in the gaseous phase.

The Raman spectra of polyatomic molecules are naturally more complicated. An important guiding principle revealed by extensive experiments is that a given bond in a complicated molecule often gives rise to a Raman frequency which is but slightly affected by variations in the structure of the remaining portions of the molecule. All incompletely substituted aliphatic compounds, for example, exhibit a Raman shift in the neighbourhood of 2934 cm.$^{-1}$. A line near 1,700 cm.$^{-1}$ is invariably found in the Raman spectra of carboxylic acids, aldehydes, ketones, acid chlorides and esters, and is naturally attributed to the presence of the carbonyl group, $=C=O$. The exact value found for the methyl, ethyl, propyl, butyl and amyl esters of formic acid is 1718 ± 3, and for the corresponding values for the esters of chloroformic and acetic acids the values are, respectively, 1775 ± 5 and 1738 ± 2 reciprocal centimetres. These variations, though genuine, are not great enough to invalidate, as a guiding rule, the principle of a virtual independence of group frequencies. In this way, characteristic Raman shifts may be allotted to atom pairs in polyatomic molecules, such as the wave number 3050 for the –C–H pair in aromatic hydrocarbons and that of 2924 for the same pair in aliphatic hydrocarbons. The spectra of amines, alcohols and mercaptans similarly yield 3370 for the –N–H group, 3650 for the –O–H group and 2572 for the –S–H group.

Higher values of the Raman frequencies are obtained when the two atoms are joined by divalent bonds, and still higher values when the same two atoms are united by the tervalent bond. Thus, when the carbon-carbon, the carbon-nitrogen and the carbon-oxygen bonds are examined, each in the three valency states, the ratio of the Raman shifts are as 1:1.63:2.10. Now it can readily be shown that the average restoring force of a linear harmonic oscillator is proportional to the vibration frequency raised to the power of 3/2, and is in fact equal to $\pi(h\mu\nu^3)^{\frac{1}{2}}$, where μ is the reduced mass. We thus see, as A. Dadieu and K. W. F. Kohlrausch first pointed out, that, for univalent, divalent and tervalent bonds between the same pair of atoms, the average restoring forces stand in the ratio of 1 to 2.08 and to 3.05. The classical theory of valency is thus quantitatively vindicated by the study of the Raman affect. It is, thus, a natural result to find that the average restoring force exerted in the carbon-nitrogen bond contained in oximes, ketimines and isocyanates is intermediate in strength between the average forces exerted, on the one hand, in amines, amides and pyrroles, and, on the other hand, in nitriles, ferrocyanides and cyanamides.

Only a few instances can be cited of the further application of the Raman technique to physicochemical problems. In the familiar conversion of the keto to the enol modification suffered by ketonic compounds, the characteristic ethylenic lines at 1632 and 1725 cm.$^{-1}$, which are present in the spectrum of ethyl aceto-acetate, are found to be absent from the spectrum of ethyl-dimethyl-aceto-acetate, which shows, however, a doublet at 1707 and 1738,

typical of the carbonyl group. In the polymerization of methyl methacrylate, the Raman line resulting from the—C=C—bond gradually vanishes, and is almost completely absent from the final polymer formed, which indicates the obliteration of the double bond during the linking up. The great similarity between the Raman spectra of the tertiary butane molecule and the tetra methyl-ammonium ion establishes a regular tetrahedral configuration for the latter. Finally, promising attempts have been made at computing, from a knowledge of the Raman frequencies, the specific heat of certain liquids and the latent heats of fusion of certain solids.

The Kinetic Theory of Gases.—With the exception of the atomic theory of matter, no theory has so powerfully influenced chemistry as the kinetic theory of gases. Its origin may be traced, through Pierre Gassendi in the 17th century, to the early speculations of the Greek philosophers, but its formulation as we now know it is due in equal measure to the German scientist, Ludwig Boltzmann, and the British scientist, J. C. Maxwell, whose classical theorems on the distribution, respectively, of energy and velocity, appeared in 1859. It is worthy of note that many of the ideas essential to the theory, though inaccurately formulated, were expressed in 1845 by J. J. Waterston, whose celebrated communication was not published until 1892. The original postulates are that the molecules constituting a gas are hard, perfectly elastic spheres, endowed with incessant translatory motion, and occupying a volume which is negligible compared with the total volume of the gas. The velocities, momenta, energies and directions of motion are not the same for all the molecules in any specimen of gas, but are distributed among them according to the formal laws of probability. Maxwell's first paper dealt chiefly with the distribution of velocities, and Boltzmann's with the distribution of energies.

Few of the postulates underlying the original theory are now regarded as valid, but enormous advances have been made by accepting them as working propositions, and by inventing additional postulates to explain divergences between theory and practice.

The kinetic theory of gases gives a logical meaning to the well-known laws of Robert Boyle, J. A. C. Charles and Amedeo Avogadro. Thomas Graham (1833) showed that the velocity of effusion of gases at a constant temperature should be independent of the pressure and inversely proportional to the square root of the molecular weight. He verified this theoretical deduction by measuring the rates of effusion of nitrogen and ethylene, which were found to be nearly equal, and the relative rates of effusion of hydrogen and oxygen, which were found to be 3.815:1.000, as compared with the anticipated value of 3.985. Atmolysis, the separation of gases by diffusion, was used by Sir William Ramsay and M. Travers to effect the isolation of helium from other gases, and by Lord Rayleigh and Ramsay in a partial separation of argon from nitrogen, using the celebrated churchwarden pipe technique. In this experiment, a mixture of gases of unequal molecular weight is made to flow through a tube which bifurcates into one tube of glass and one formed of two churchwarden pipes joined together. The lighter gas diffuses through the clay walls more readily than the heavier one, and partial separation can be effected. The formula (O_3) of ozone was first established as a result of diffusion experiments.

According to the kinetic theory, the specific heat of gases, and the ratio (γ) of the specific heat at constant pressure to that at constant volume, should be independent of the temperature and determined by the number of atoms in the molecule. The first of these conclusions has proved to be untrue, and the real effect, which is an increase in the specific heat with a rise in temperature, has only recently been understood, in terms of the quantum theory. The second conclusion, though limited in validity, has been of direct value to chemistry in allowing an experimental determination of the number of atoms in molecules. Rayleigh and Ramsay (1894) found γ, from the velocity of sound in the gas, to be nearly 1.67 in the case of argon, and concluded that this molecule was therefore monatomic.

Ramsay (1879) gave the first kinetic interpretation of the Brownian movement as the motion of small particles resulting from molecular impacts with molecules of the surrounding medium. This interpretation led later (1905) to the kinetic theories of the effect by Einstein and by Smoluchowski, and to the first reliable experimental value of the Avogadro number, by Perrin (1909). The Brownian movement of smoke particles studied by E. N. da C. Andrade and R. C. Parker (1937), offers direct visual evidence of the effects of collisions by gas molecules on the movements of small particles of suspensoid.

The coefficients of viscosity, diffusion and thermal conduction are given by the kinetic theory in terms of the molecular diameters (P. G. Tait, 1886). The three methods have afforded early values of molecular radii, which agree among themselves, and with those obtained by numerous other methods, of which only two—both due to Rayleigh—need be mentioned here. The first (1871) depends on the refraction of light by particles of molecular dimensions, and the second (1905) is based on the computed minimum thickness of an oil layer found necessary to stop the Brownian movement of camphor particles in the water-air interface. The value estimated by Rayleigh by the second method was 16×10^{-8} cm. His kinetic treatment of the effect forms the basis of the Langmuir-Adam-Rideal (I. Langmuir, N. K. Adam and E. K. Rideal) trough techniques for examining surface films.

The kinetic theory in its original form accounts only for the kinetic pressure exerted by a gas, and ignores intermolecular cohesion. The second factor is necessary to explain the condensation of gases into liquids, a process much investigated experimentally by T. Andrews (1876) in his work on critical phenomena and theoretically by James Thomson (1871) and J. D. van der Waals (1871) in their theories of the continuity of states. The existence of cohesive forces between molecules is manifested by the cooling which under ordinary conditions results during the expansion of a gas. By developing the porous plug experiment of J. P. Joule and James Thomson, both James Dewar (1900) and M. Travers (1900) succeeded in liquefying hydrogen, which is one of the two gases that Michael Faraday failed to liquefy by other means. It is the liquefaction of gases, and of helium in particular, that has enabled all the recent work to be done on physical and chemical properties of matter at low temperatures.

The classical work of Sir J. J. Thomson on the conduction of electricity through gases follows the observation of Sir William Crookes (1881) that the viscosity of gases at low pressures is less than that predicted by the kinetic theory.

The fundamental ideas of the kinetic theory of gases have been extensively applied to systems other than the gaseous system. In particular, they have greatly influenced the development of the theories of solution, which stimulated the precise experimental work of E. G. J. Hartley and the earl of Berkeley, and led to van't Hoff's hypothesis of osmosis.

The kinetic theory in its primitive form affords expressions for the number of collisions taking place in unit time between gas molecules and unit area of a surface and between gas molecules themselves in unit volume. The former of these expressions was compared by J. W. Strutt (afterward Lord Rayleigh) with the rate of reduction of solid silver oxide by gaseous ozone (1912), and the latter was compared by M. Trautz (1916) and W. C. McC Lewis with the rate of decomposition of gaseous hydrogen iodide (1918) The collision hypothesis, supplemented by the fundamental conception of a random distribution of energy, has since dominated the field of chemical kinetics and surface catalysis.

Extensions of the kinetic theory of gases to cover the repulsive and attractive forces exerted between the molecules have been made by A. W. Chapman (1915) and by Sir John Lennard-Jones (1924). The theory has also been extended to the kinetics of solutions (1933).

To the experimental chemist, the kinetic theory has given a picture of how molecules behave, and has made it possible for him to construct in his imagination the types of molecular interactions which constitute chemical change. It has given him a lively and interesting method of approach to many of his problems, a method which is neither as formal as that of thermo-

dynamics nor as difficult as that of statistical mechanics.

The Maxwell-Boltzmann Law.—Reference has already been made to the theorems of Maxwell and of Boltzmann on the distribution, respectively, of momenta and energies among gaseous molecules. Boltzmann proved that the fractional number of molecules retained in a system at constant volume and temperature which possess an energy, E, per molecule, is proportional to the term $e^{-E/kT}$, where e is the base of the natural logarithms, T the absolute temperature on the Kelvin scale, and k a constant which is independent of the system, and is a universal constant now bearing Boltzmann's name. As E increases, the Boltzmann factor $e^{-E/kT}$ decreases. Hence, the number of molecules which are energetically well-endowed is relatively small, while the number of molecules with lower energies is large. Energy among molecules is thus like money among men; the poor are numerous, the rich few. This law has proved to be one of the securest possessions of natural science, and has survived the storms of quantal mechanics which within recent years have overthrown so many of the stately edifices constructed in the placid days of classical mechanics. Salvador de Madariaga has held that the derivation of the Maxwell-Boltzmann law offers the best example of pure logical deduction evinced since the middle of the 19th century. With its derivation we cannot here be concerned, but some indication must be given of its far-reaching effects on the development of many physicochemical themes.

When a liquid is kept in a closed vessel, like wine in a bottle, the molecules in the closed system distribute themselves between the condensed and vaporous phases in such a way that (except at the critical temperature) the molecular concentration in the vapour is considerably less than that in the liquid. The explanation, according to the Maxwell-Boltzmann law, is that only those molecules of the liquid which possess an energy L can vaporize. L is the latent heat of vaporization, and is usually large; hence the number of liquid molecules which have sufficient energy to detach themselves from their neighbours in the condensed state is relatively small. To revert again to our anthropomorphic analogy, it is as if transit from the liquid to the vapour states requires the expenditure of much energy, as the transit from a slum in England to a hotel on the Riviera requires the expenditure of much money.

A very similar state of affairs prevails in the case of electrons in metals. It is known that the atmosphere above the surface of a cold metal is electrically neutral. At high temperatures, however, all metals emit a stream of electrons which constitutes the so-called "thermionic current" now so extensively utilized in the construction of electronic tubes. O. W. Richardson discovered that the logarithm of the current is proportional to the reciprocal of the absolute temperature. In other words, the current itself has a strength which is proportional to $e^{-W/kT}$, where W is positive. In terms of the Maxwell-Boltzmann law, W can be identified as the work which must be expended to remove an electron from inside the metal. It is known as the thermionic work term, and has been shown by Einstein to be equal to the quantum, $h\nu$, of light necessary at the threshold frequency to emit electrons in the photoelectric effect.

It is well known that high altitude aviators must carry their own supply of oxygen with them, because the concentration of this vital gas at great heights is too attenuated to support life. The distribution of concentration with height is again governed by the Maxwell-Boltzmann law. The concentration, n_1, at a height H_1, is proportional to $e^{-mgH_1/kT}$, where m is the mass of one molecule, and g the gravitational constant. At the same temperature, but at another height, H_2, the concentration, n_2, is proportional to $e^{-mgH_2/kT}$. The ratio of the concentrations at two heights differing by H is thus $n_1/n_2 = e^{mgH/kT}$. The earth's atmosphere is not the most suitable medium for testing this equation, because the molecules are invisible, and because of the overwhelming complications due to meteorological factors. Working with colloid particles suspended in water at a constant temperature, however, the numbers may be counted by visible means, and the difference in height measured microscopically. This Perrin did in his classical researches which both verified the law and afforded an experimental determination of the Boltzmann constant, k.

The Maxwell-Boltzmann law forms the basis of the modern theories of electrolytic solutions, first proposed by S. R. Milner in 1917 and improved by P. Debye six years later. The electrolyte is regarded as dissociated completely or partially into ions, in a medium of uniform dielectric capacity. The random distribution of ions in solution differs from the random distribution of molecules in a gas, because of the strong Coulombic forces exerted between them. On applying the Boltzmann law to a determination of the ionic concentration in the neighbourhood of any selected ion, we see at a glance that the selected ion will be surrounded by a relatively high concentration of ions of the opposite sign, and by a relatively low concentration of ions of the same sign as its own. This uneven distribution of electrical charges leads to the formation, around each ion, of a cloud of ions, carrying a net charge of opposite sign to its own. The total electrostatic energy of ionic solutions is thus diminished, and is less than the electrostatic energy of the same number of ions in an infinitely dilute solution. In extremely dilute solutions of electrolytes of low valency type, the Milner-Debye theory has been corroborated in various ways, for example, by measuring cryoscopically the activity coefficients of electrolytes, by determining the ionic mobility in electrical fields and by estimating the effect of dilution on the heat of dissolution. The assumption that the Maxwell-Boltzmann law applies to electrolytic solutions is one of its least debatable ones, and is certainly a less dubious one than that of the invariance of the dielectric capacity of the medium.

The intensity of a line in the Raman spectrum is proportional to the stationary concentration of excited molecules in that state, transition from which causes the emission. If I_b and I_r stand, respectively, for the intensities of the lines displaced toward the blue and red ends of the spectrum from the central position of the undisplaced line, then the following expression holds, according to the Boltzmann law for the ratio of the intensities: $R = I_b/I_r = e^{-Eq/kT}/e^{-Ep/kT}$. But, from our discussion of the Raman effect, we know that $E_p - E_q = 2h\nu_R$; hence $R = e^{2h\nu_R/kT}$. As the temperature rises, the ratio approaches unity. By plotting $\log_e R$ against $1/T$, this relation has been verified independently by P. Daure and by L. S. Ornstein and J. Rekveld. The gradient determined from experiment yields the value of 4.79×10^{-11} degree-seconds for h/k. Taking k as 1.372×10^{-16} erg per degree, h thus becomes 6.56×10^{-27} erg-second, satisfactorily confirming the more accurate estimates based on the photoelectric effect and the spectrum of atomic hydrogen.

Finally, it has been shown by J. J. Hood (1878) and by S. A. Arrhenius (1889) that the logarithm of the velocity coefficient of a chemical reaction is linearly related to the reciprocal of the absolute temperature. The velocity itself is thus proportional to $e^{-E/kT}$, where E is termed the energy of activation. This relationship is the foundation of chemical dynamics.

In these instances of the application of the Maxwell-Boltzmann law, care has been taken to emphasize the proportionality between, rather than the identity of, the fractional number of energized molecules and the factor $e^{-E/kT}$. The ratio of the number of active molecules to the total number is equal to the exponential term only when the energy concerned can be expressed as the sum of two quadratic terms. A generalized form of the law has been derived by A. Berthoud (1911).

Chemical Kinetics.—Instructions for the preparation of chemical compounds frequently contain such phrases as "heat substance A with substance B for two hours." The time element is important in the process; its inclusion aims at the most abundant yield of the desired commodity. This process of preparing chemical compounds is, of course, one of the principal activities of the chemist. Organic chemists often know, almost by divination, how long to allow the reactants to react in order to obtain the best yield. Physical chemists have two guides to help them. One is thermodynamics, which can, in principle, tell them how far any reaction can go, given all the relevant thermal data; the other is chemical kinetics, which can, in most cases, tell them how fast the reactions can go. Chemical kinetics, since its inception by Ludwig Wilhelmy in 1850, has proved to be one of the

most popular branches of physical chemistry, and one which has shown the most consistent and continuous growth. It introduces time as an essential variable in chemical systems. The laws of chemical kinetics, rigidly formulated, all contain time as a factor, and reduce, when the time is extended to infinity, to the equilibrium laws of chemical thermodynamics. The formal side of chemical kinetics deals with the velocity of chemical change in all systems. In its development, however, a machinery has been created for handling a variety of problems outside its formal sphere, and for the solution of problems which have proved too difficult for chemical thermodynamics or statistical physics. Adsorption, discussed in the first section of this article, provides a good example. Other problems which have been successfully approached by the method of chemical kinetics are the standard electrode process, overpotential, the conduction of electricity through gases, vaporization, enzyme structure, dissolution, the persistence of clouds and the disorderliness of simple binary systems in the condensed phases.

Clearly one condition that must be fulfilled before molecules can react is that they should meet. If an encounter between two molecules is a sufficient condition for reaction, the rate of chemical change should be equal to the rate of collisions. Two physical changes have already been discussed from this point of view, and it has been shown that the rate at which colloid particles in the gas phase and in solution coagulate and the rate at which electronically excited molecules in both systems are deprived of their energy are equal to the rate at which the molecules meet. Binary collisions are thus a necessary but not always a sufficient condition for the occurrence of these physical changes. When, however, we examine the rate of chemical processes in the light of the collision hypothesis, we find a wide disparity. Experiment shows that only a very small fraction of the total number of collisions is fruitful. M. Trautz, in 1916, and W. C. McC. Lewis independently in 1918, argued that, since only molecules possessing exceptional energies can undergo chemical change, the rate of reaction should be compared, not with the total rate of collisions, but with the rate of activating collisions, which, according to the Maxwell-Boltzmann law, is less by the factor $e^{-E/RT}$, where E is the energy of activation. Experiment shows that the energies of activation for the decomposition of ozone into oxygen, of hydrogen iodide into hydrogen and iodine and of nitrous oxide into nitrogen and oxygen are, respectively, 26,365, 47,275 and 61,550 calories per gram-mole. The Boltzmann factors are thus extremely small. Nevertheless, when multiplied by the total collision rate, they yield products which are experimentally indistinguishable from the rates of chemical reaction. This conclusion forms the basis of the collision theory of chemical change.

An application of the same reasoning by J. A. Christiansen, in 1924 to reactions in solution met with less success, in that a considerable discrepancy appeared between the observed rates and those computed on the basis of the collision theory. It was, therefore, maintained for some years that the theory, though apparently applicable to gases, was not, without drastic modifications, applicable to solutions. In 1932, however, it was revealed that hundreds of reactions in solution, some of which had been examined with great accuracy during the 19th century, fitted in perfectly with the predictions of the collision theory. Thousands more have since been discovered, and there now remains no doubt that the theory of activating collisions, sometimes in revised forms, is fundamentally sound. Among these numerous reactions are to be found the etherifications of alkyl halides by organic bases such as sodium methoxide, potassium phenoxide and alkali β-naphthoxides, the replacements of halogen and hydroxyl from aliphatic compounds by anions in various solvents, the union of ethyl bromide with diethylsulphide in hydrolytic media, and the formation of the bicarbonate ion from carbon dioxide and the hydroxyl ion in aqueous solution.

Occasionally when two chemical compounds interact, only one of them suffers chemical change, while the other which is termed a catalyst, emerges from the reaction unchanged. These catalytic reactions are essentially bimolecular, and their rates, with few exceptions, are also in agreement with the prediction of the collision theory. The catalytic mutarotation of the reducing sugars by hydrogen ions, the catalytic decomposition of ethylene di-iodide by iodine atoms, the catalytic mutarotation of beryllium benzoylcamphor by cresol, the catalytic conversion of the picryl ethers of benzophenone oximes by acetone and nitromethane are all processes the rates of which are given by the expression: Number of molecules reacting in unit volume in one second = number of collisions between catalyst and reactant in unit volume in one second $\times e^{-E/RT}$.

If only those molecules which possess considerable energies in excess of the average can react, on what, one may ask, is this energy expended? The answer was first given by W. Heitler and F. London, in 1927. Chemical change involves, first the loosening, and finally the breaking of a chemical bond and usually the simultaneous formation of a new bond. To break a bond requires energy; and this, duly compensated by energy liberated in the formation of another bond, constitutes the energy of activation. Heitler and London showed how the energy of activation could be calculated from first principles for very simple chemical changes, such as the following reaction between an atom, A, and a diatomic molecule, BC; $A+B\text{-}C \rightarrow A\text{-}B+C$. The initial system corresponds to a free atom, A, at an infinite distance from the stable molecule, BC, the atoms in which are at their normal, or equilibrium, distance apart. This state of affairs we may describe by saying that r_{AB} is infinite, and $r_{BC}=r^{\circ}_{BC}$. The final state, after the completion of reaction, corresponds to a free atom, C, at an infinite distance from the stable molecule, AB. This state of affairs may be summarized by saying that $r_{AB}=r^{\circ}_{AB}$, and that r_{BC} is infinite. Between these stages, the internuclear distances, r_{AB} and r_{BC}, must have had comparable magnitudes, and this very nearly corresponds to the activated state, as D. S. Villars (1930) independently concluded. The difference between the energy of the complex $A \ldots B \ldots C$ in the activated state and the energy of the initial system is the energy of activation. The solution of the dynamic problem is somewhat tortuous, and demands an exact knowledge of the forces exerted between the various atoms. The results of calculations on the energy of activation of the reaction between the bromine atom and the hydrogen molecule ($Br+H\text{-}H \rightarrow Br\text{-}H+H$) are shown graphically in fig. 2. From the energy contours, which are given in kilocalories per gram-mole, it is seen that the easiest of an infinite number of passages from the initial atomic configuration (top left-hand corner) to the final atomic configuration (bottom right-hand corner) requires an ascent of 22,000 calories, and that the two internuclear distances at this pass height are equal to 1.43×10^{-8}cm. The former value is in agreement, though not directly comparable, with the experimental values obtained by Max Bodenstein and H. Luetkemeyer, and later by F. Bach, K. F. Bonhoeffer and E. A. Moelwyn-Hughes, using both ordinary hydrogen and its heavy isotope.

The first calculations of the energy of activation of triatomic reactions according to the Heitler-London method were made by Henry Eyring and Michael Polanyi, on the ortho-para conversion of hydrogen, which as Adalbert Farkas and Bonhoeffer had shown, proceeds by the same mechanism as that previously established for the hydrogen-bromine reaction. Attempts at computing the energies of activation of more complicated reactions have also been made.

If all chemical reactions conformed to the collision theory, we would find chemical changes to proceed with wide ranges of velocities, from the fast reactions which require little energy, to the slow reactions which require much, but the changes would, as a rule, be orderly, and would never get out of hand. It is well known that many chemical reactions run riot; they proceed with accelerative rates and lead to explosions. The explanation of the occurrence of thermal explosions and of numerous phenomena with which they are akin has been given, principally by Max Bodenstein, R. Willstaeter, Fritz Haber, J. A. Christiansen, H. A. Kramers and N. Semenoff, in terms of the chain theory of chemical change. The primary notion is one of "hot" molecules; *i.e.*, of chemically reactive molecules produced during the activation process, and capable of retaining their energy until an opportunity

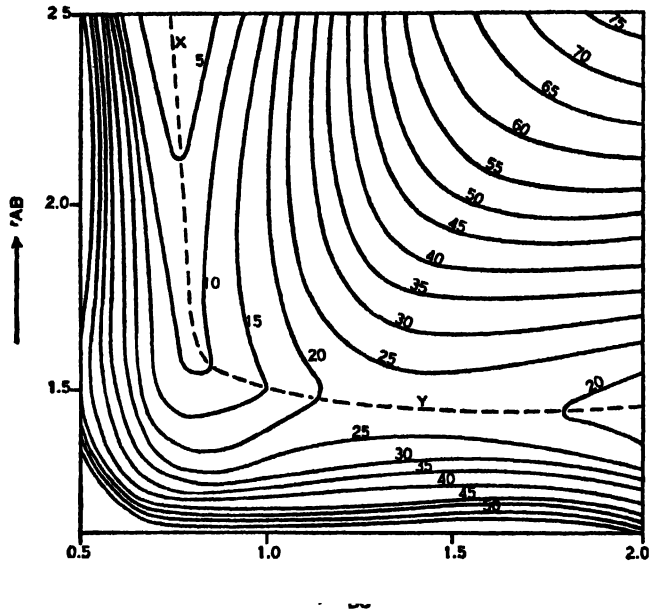

FIG. 2.- POTENTIAL ENERGY CURVES FOR THE SYSTEM Br..... H... H

affords of passing it on to fresh reactant molecules, which in turn become activated. One initial activation can thus lead to the conversion of many molecules. The average number so destroyed per unit activation is termed the chain length. This may amount to many thousands of molecules, not only in gases, but in solution, where deactivations by solvent molecules, though possibly not entirely absent, are by no means as probable as they were at one time thought to be. It can readily be shown that, if, in a system containing n molecules per c.c., the decomposition occurs by the mechanism under discussion, the rate of reaction becomes $-\frac{dn}{dt}=\frac{k_1 n^2}{(k_1/k_3)n+(1-\alpha)}$, where k_1 governs the rate of formation of active reactants by collisions between normal molecules, k_4 governs the rate of destruction of active reactants in deactivating collisions with normal molecules, and k_3 is the unimolecular constant for the spontaneous decomposition of active reactants. The important term, α, takes account of the fact that not all collisions between normal molecules and active products which lead to deactivation are effective in regenerating active molecules of reactants. In all thermal, or "quiet" reactions, α is zero. Chain reactions are characterized by real values of α. In simple cases, the chain length is simply the reciprocal of $(1-\alpha)$, which may be very large when α approaches unity. Branching chains are characterized by values of α exceeding unity, in which case the denominator in the general rate equation may become zero, and the rate itself may become infinite. This is what is generally meant by an explosion.

The chain theory has been employed to interpret numerous phenomena in the kinetics of chemical changes in gaseous and liquid systems. It can successfully account for the apparently unimolecular behaviour of molecules decomposing in systems of high concentration, though the rate of production of active molecules itself is a bimolecular process, and is therefore dependent on the square of the concentration, and for the distinction between the mechanism of hydrolytic and oxidative enzymic reactions.

The extensions of chemical kinetics resulting from the quantum theory are concerned with the more exact determination of the energy of activation, and with the possibility (precluded according to the classical theory) of the transit of a molecule over a potential barrier while not possessing sufficient energy to surmount it. The latter phenomenon is known as the tunnel effect, and is relevant only for light molecules penetrating barriers at low temperatures.

Intermolecular Energy.—When molecules come near enough to influence one another, at least two forces are brought into play: one of attraction, and one of repulsion. If molecules did not exert forces of attraction, they would not cohere, as they manifestly do in the liquid and crystalline state. Were there no forces of repulsion, the forces of attraction would be supreme, and nothing would prevent molecules from annihilating one another. Much as human conduct is determined by a conflict of loyalties, molecular behaviour is, to a large extent, determined by the balance struck between the forces which tend to pull molecules together and those which tend to push them apart. The detection of the kind of intermolecular force at work in particular systems has been an important new feature of the physical chemistry of the 20th century.

More is generally known about attractive than about repulsive forces. When, for example, two ions, of valencies z_A and z_B, are held at a distance, a, apart, there exists between them, *in vacuo*, an energy which C. A. Coulomb has shown experimentally to be inversely proportional to their separation. In fact, the energy is $u=z_A z_B \epsilon^2/a$, where ϵ is the electronic charge (4.77×10^{-10} electrostatic units). The force, X, is given by the general equation $X=\frac{du}{da}$, which, in the present example, becomes $z_A z_B \epsilon^2/a^2$. Thus, when both ions have charges of the same sign, their mutual energy and the force acting between them are positive, denoting repulsion. When the ions have charges of opposite signs, their mutual energy and the force acting between them are negative, indicating attraction. It is this Coulombic force which, as Ernest Rutherford and Niels Bohr first showed, accounts for the tenacity with which electrons in atoms are held to the positively charged nuclei. In crystalline salts, the units are positive and negative ions, such as the sodium and chlorine ions in common salt; and here also, the binding force is almost entirely due to the Coulombic attraction between the ions. It is thus easy to understand why the lattice energy (*i.e.*, the energy required to transform the crystalline salt into gaseous ions) is four times as great for a bi-bivalent salt as it is for a uni-univalent salt of the same molar volume. The Coulombic energy of a pair of ions separated by a medium of dielectric constant, D, is less than that *in vacuo* at the same separation by the ratio $D:1$. The dielectric constant of water at ordinary temperatures is about 80, hence the force attracting cations to anions in aqueous solution is relatively small, and can be effectively combated by the kinetic energy resulting from their motion.

The energy of interaction of an ion of charge $z_A\epsilon$ and a dipole of moment μ_B which is inclined at an angle of θ to the line joining their centres is given approximately by the equation $z_A\epsilon\mu_B\cos\theta/a^2$. The mutual energy may now be positive or negative even for a system containing the same ion, because $\cos\theta$ can be positive or negative. It is this term which explains the comparative stability of inorganic ions in solvents of high dielectric constant, such as water, alcohol and nitromethane. In solution, each ion attracts the solvent molecules, and forms a shell around itself, with each solvent molecule orientated in the position of minimum energy. The exact number of solvent molecules which forms the first sheath has not yet been established, although the co-ordination number of many ions in crystals of hydrated salts is known. When chemical reaction takes place between an ion and a polar molecule, the approach of the ion to the molecule is influenced by the position and magnitude of the dipolar groups which the latter contains. The interaction of the ion with all the dipoles constitutes an important component of the energy of activation, and thus modifies the velocity of reaction. In the light of these considerations, it is now, for the first time, becoming clear why the substitution of a given group in the benzene ring may hasten or retard chemical reaction, according to the position, relative to the point of attack, which it occupies.

When two dipoles interact, four angles, in addition to the distance apart of their centres, are required in order to express

their mutual energy, which now varies inversely as the third power of the distance, as may easily be derived by applying Coulomb's law to the interaction due to each pole, or by carrying out experiments with bar magnets, which are the macroscopic and magnetic analogues of the microscopic and electric moments in molecules. The interaction of permanent dipoles probably explains most of the anomalous properties of binary liquid mixtures, such as that of acetone and chloroform.

The next force of physicochemical interest is that which comes into play when an ion approaches a nonpolar molecule. The field generated by the ion induces an electric moment in the molecule, and the net interaction energy that results is readily shown to be directly proportional to the square of the ionic charge and to the polarizability of the molecule, and inversely proportional to the fourth power of their distances apart. An example is afforded by the attraction of the highly polarizable iodine molecule for the iodide ion; iodine is very sparingly soluble in water, but readily soluble in aqueous iodides.

There are many forces which vary inversely as the seventh power of the intermolecular distance. The most important is the so-called "dispersion force," which London (1930) has shown to be related to the frequency of vibration of the electrons in the molecules. This is the force which accounts for the cohesion of nonpolar molecules in the condensed state. In the case of the inert elements, and of symmetrical molecules such as chlorine, carbon tetrachloride and benzene, the dispersion force is the only attractive one; it comes into play also even in polar cases, where it is often dominant. Deviations of the behaviour of real gases from that of ideal gases are in large measure caused by the presence of London forces.

As stated above, rather less is known of the repulsion forces. These may, it is thought, be exponentially related to the intermolecular distance, or they may vary inversely with respect to the distance raised to some power which must be higher than the power governing the attractive forces. If we provisionally adopt the latter supposition, the total interaction energy of a molecular pair, at a distance a apart, may be expressed as the sum of the repulsive and the attractive energies: $u = Aa^{-n} - Ba^{-m}$, where n is greater than m. This relationship was applied by Gustav Mie, in 1903, to a variety of chemical and physical problems. He showed how this equation, which represents the interaction energy of an isolated pair of molecules, can be extended to the evaluation of the interaction energy of a large number, mutually influencing one another, and derived, in terms of the constants, A,B, and the integers, m, n, illuminating expressions for the isotherms, the compressibilities and the expansivities of condensed systems. Mie's equation has, in later years, been applied by Max Born to the study of solids and by Lennard-Jones to the study of gases.

Other types of forces, which are only partially electrostatic in origin, are exerted between the atoms in a molecule, and give rise to the variety of chemical bonds. We have already seen that the average interatomic force between two atoms varies linearly with respect to their valencies. How the interatomic forces vary with the distance apart of the nuclei is a problem which is, as yet, only dimly understood. Progress is being made on empirical lines. There is, however, no obscurity about certain conditions which experiment imposes on the general nature of the force laws. It is certain, for example, that the force tending to restore the atoms to their equilibrium positions after they have been slightly displaced therefrom must increase in proportion to the displacement, and thus obey Robert Hooke's law. Only in terms of such an elastic force can the essential harmonicity of the interatomic vibrations, which is proved alike by infra-red and Raman spectroscopy, be understood. If, however, only elastic forces were at work, the more we drew the atoms apart, the stronger would be the forces of restitution, and the less would be the likelihood of bond cleavage. Experiment shows that, with increasing separation, the atoms come under the influence of a very weak force, which eventually vanishes as the interatomic distance reaches infinity. Finally, the interatomic forces must be consistent with the thermal and spectroscopic evidence on the energy of dissociation, as well as on the known values of the equilibrium separation and the fundamental vibration frequencies. These guides suffice to indicate the general way in which the force varies with the distance, and several empirical expressions embodying these essential features have been advanced. The most widely used is one given by Philip M. Morse, in 1929.

Rather special assumptions have to be made concerning the forces responsible for the properties of metals—their hardness, stability, lustre and high powers of conducting both heat and electricity. The essential features of the elementary model of metals is that the framework is provided by the nuclei, and that the whole of the volume of the metal is accessible to the valency electrons. High electrical conductivity is thus intelligible. The attractive energy is provided by the Coulomb forces between the cations and the mobile electrons, and the repulsive energy is provided by the kinetic energy of the electrons. The latter, according to the quantum theory, is much greater than one would expect on classical arguments, and has been evaluated by Enrico Fermi. The energy required to expel an electron from a metal, which can be measured photoelectrically or thermionically, thus equals in magnitude the difference between the Fermi and Coulomb energies. Such a simple model of metals, is, however, deficient in many ways. It cannot, for example, give an explanation of the elastic constants, such as the compressibility and the fundamental vibration frequency, which is consistent with the specific heat. Other forces must come into play in metallic cohesion, and research on their nature is being actively carried out by many investigators. A set of potential energy curves for the diatomic molecules of the alkali metals is shown in fig. 3, where the energy per pair of atoms is expressed as a function of the internuclear distance.

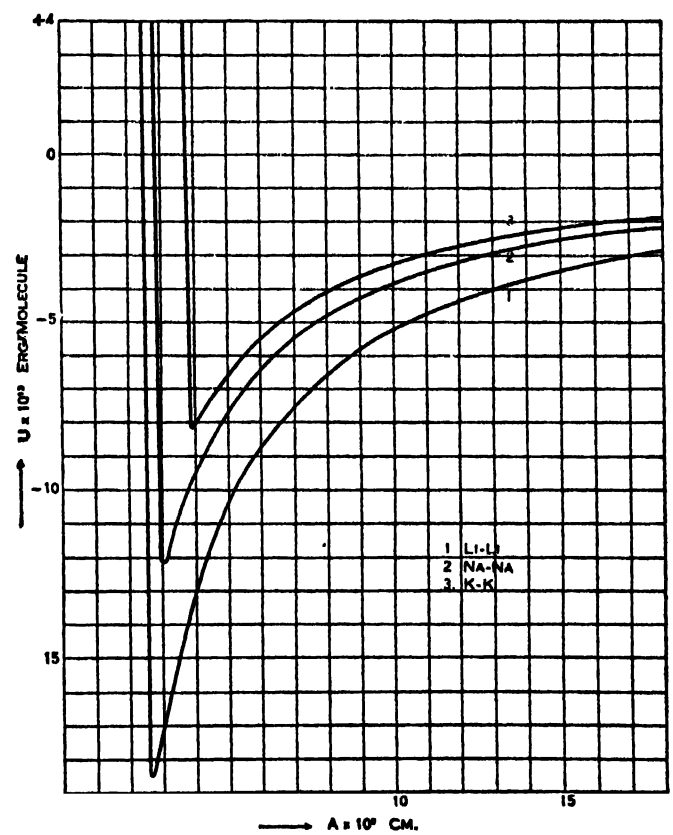

FIG. 3.—THE POTENTIAL ENERGIES OF PAIRS OF ALKALI METAL ATOMS

The Liquid State.—The liquid state has consistently been the most neglected of the various states of matter. Attention has been paid almost exclusively to the sister states called gaseous and crystalline. Classical kinetic theory has been progressively applied for 100 years to the study of the gaseous state, and the quantum theory has been vigorously used for nearly 50 years in the study

of solids. It is only since the 1920s that either theory has been applied to liquids, except by a very small number of investigators, of whom Gustav Mie is the foremost. Two reasons may be advanced to explain the neglect. In the first place, the liquid state is the intermediate state of matter—that state which matter naturally assumes in passing from the solid to the vapour—and its properties are not so pronounced or sharp-edged as those of the extremes which flank it. In the second place, the classical theory appeared adequate to our knowledge of gases, and the quantum theory to our knowledge of solids. Neither suffices to explain what we know of liquids. The elucidation of their nature requires the full resources of both classical and quantal theories.

Solids are characterized by low potential energies, resulting from powerful cohesive forces, which tie the molecules together, usually in an orderly pattern, and prohibit motion, except an oscillation of small amplitude about the mean position of equilibrium. Gases are characterized by high potential energies, resulting from weak cohesive forces, which allow free motion and a completely random molecular distribution. A liquid, with its intermediate potential energies and moderate cohesive forces, has neither the orderliness of a crystal nor the randomness of a gas. Its molecules, though not constrained to vibrate about fixed positions in space, are, at the same time, not capable of unrestricted motion throughout the total volume.

The mean free path of a molecule in a crystal is less than, and of a molecule in a gas is greater than, the linear extension of the molecule. In a liquid, the mean free path is, under ordinary conditions, commensurate with the molecular dimensions. W. T. Kelvin once used a telling analogy of molecules with ships. In gases, the molecules are like ships on the high seas, which only seldom come within reach of one another; in solids, the molecules are like ships under construction in the dry docks of the building yard; in liquids, the molecules are like ships on a navigable river or in a busy harbour.

Largely because of the prominence given in classical physical chemistry to the idea of a continuity of state, the liquid state has usually been approached from the vapour end; textbooks almost invariably introduce it as the highly compressed fluid. There has been a tendency during recent years to approach the liquid state from the solid end, and, in fact, the results of experiments on the scattering of X-rays and the diffraction of electrons by liquids have indicated a striking similarity between the molecular arrangements in solids and liquids at low temperatures. There is at present some danger of over-emphasizing the crystal-like features of liquids, and to regard them as slightly released solids. How the right balance is to be struck is decided by temperature, within the relatively narrow region—bounded by the triple and critical points—of the liquid's natural existence in equilibrium with its vapour. At the triple point, a liquid demonstrably retains many of the characteristics of a solid, while acquiring to some extent the characteristics of a gas. The former are not completely lost nor the latter fully developed until the critical point is reached.

The simplest liquids to examine are those formed of nonpolar molecules, because the potential energy is then dependent only on the distances apart, and not on any angular function. Molten metals and salts should also be treated as specialized liquids, or, perhaps more logically, as solutions rather than as pure liquids. Even in the interpretation of the facts established concerning simple, nonpolar liquids, there has appeared a great variety of theories, of which but a few can be mentioned here.

It has long been suspected that many of the properties of liquids are more closely related to their free volume than to their actual volumes. In the theory of J. D. van der Waals, the free space in a gas consisting of noncompressible spheres is taken as the difference between the actual volume and a forbidden volume, the latter being identical with four times the sum of the volumes of the incompressible spheres. Coupled with a not unreasonable postulate concerning the attractive forces, this idea leads to the conclusion that the free space per molecule at the critical point is two-thirds of the critical molecular volume. An alternative assumption concerning the interaction energy led C. Dieterici to identify the forbidden volume with one-half the critical volume. Although neither conclusion can now be sustained, they both bring home the essential truth that the free volume in liquids increases as the temperature is raised. G. Jaeger's important extension of the free space theory is to allow for the possibility that the free space is a function, not only of the total volume and the total number of molecules, but of the temperature also. The extended theory is more consistent with the isotherms of the vapours and the internal pressures of the liquids. Although it is not always easy to evaluate the free volume in liquids, there is no difficulty in obtaining, at any temperature, the ratio of the free volume in the saturated vapour phase to the free volume in the liquid. Dieterici (1898) showed by the method of chemical kinetics and W. C. McC. Lewis (1912) by the method of thermodynamics that this ratio is simply the inverse of the Boltzmann factor, with the internal heat of vaporization as the energy term. At relatively low temperatures, the saturated vapour has a volume which is virtually identical with the free volume; under these conditions, the absolute free volume per molecule of liquid and the vapour pressure of the liquid in terms of its volume are readily obtained. The molecular free volume of water at 25° C., for example, is found to be 7.27×10^{-26} c.c.

In these early forms of the free space theory of liquids, the total free volume is assumed to be evenly distributed throughout the liquid, each molecule claiming, as it were, its own *Lebensraum*. The randomness of molecular distribution and energies envisaged in the kinetic theory suggests that the free space may be unevenly distributed. There can be, in other words, more free space in one region than in another. This argument leads naturally to the conception of holes in the liquid. Many versions of the theory of holes have been advanced during the 20th century (*e.g.*, by H. Eyring and by M. Fuerth). It is an attractive theory, capable of explaining phenomena not readily understood by other means, and one that is developing harmoniously with the theories of the solid state. The expansion of volume which most liquids enjoy on fusion can be attributed to the creation of holes; diffusion in liquids becomes readily intelligible; viscosity can be treated, not as the passage of molecules in the direction of viscous flow, but as the movement of holes in the opposite direction; liquids may be regarded as solutions of holes in matter, and vapours as solutions of matter in free space; the diminution of liquid density with an increase in temperature may be attributed to the increase in solubility of holes.

The cluster theory of fluids, developed by M. Reinganum in 1901, was revived in 1923 by Sir C. Venkata Raman, who applied it to the problem of the temperature dependence of the viscosity of liquids. The governing notion is one of localized molecular order, not extending to great distances. The representative molecule in a liquid is regarded as capable in maintaining order among the small number of members forming the family circle, while lacking control of those placed farther afield. Molecules in the orderly groups form clusters exothermally, and therefore in concentrations which diminish as the temperature is raised. The transport of momentum through the liquid is due not solely to the translation of molecules, but partly to the transmission of elastic waves through the groups of relatively stationary molecules. The cluster theory thus explains why the viscosity decreases somewhat rapidly with a rise in temperature. Direct experimental evidence for localized molecular order in certain liquids has been afforded by experiments on the scattering of X-rays, which afford a novel and fascinating method for tackling the long-neglected problem of the physical chemistry of liquids.

ANALYTICAL CHEMISTRY

Analytical chemistry has for its purpose the determination of the constituents of which a substance or mixture is composed by methods which are qualitative when the identity only is ascertained, or quantitative when the quantity or proportion is determined. If the constituent chemical elements only are determined the process is called an ultimate analysis; such analyses are often applied to organic compounds. In the analysis of inorganic substances additional information is usually obtained in regard to the state of association and oxidation of the elements. This is true because a large proportion of the methods for the analysis of inorganic substances involve treating an aqueous solution of the substance to be analyzed with known chemicals, termed reagents, which cause specific chemical changes or reactions. The chemical reactions of such substances in aqueous solutions are mainly those of electrically charged particles or ions, which they yield, and the nature of the ions may vary with the state of association and oxidation of the elements in their various compounds.

Analyses which are carried out in solutions are often called wet methods in order to distinguish them from dry methods whereby the material is examined in the dry state. The latter methods may involve observation of the effect of heat alone upon the substance, or treatment of the substance with a solid reagent at a temperature sufficient to cause fusion and the formation of characteristic compounds; or other physical phenomena, such as the spectrum obtained at high temperatures, may be observed.

The methods of quantitative analysis can be classified as follows: (1) Gravimetric, in which the constituent to be determined is weighed after being separated, usually by precipitation from an aqueous solution, in the elementary state or as some compound of definite composition. Such methods are called electrolytic when the precipitate is deposited on an electrode by passage of an electric current through the solution. (2) Volumetric, in which the volume of a reagent solution of known concentration required to cause a definite reaction is measured. In gas analysis the constituent is converted into a gas and the volume of the gas measured. (3) Instrumental, in which some physical property associated with the constituent to be determined is measured by means of an appropriate instrument. Some of these properties and the instruments used in measuring them are: colour, colorimeter; density, pycnometer; turbidity, nephelometer; spectrum, spectrograph; refractive index, refractometer.

Analytical methods are also classified as macro when the weight of the substance taken for the analysis is of the order of grams, as micro with milligram quantities and as ultramicro with microgram quantities.

INORGANIC ANALYSIS

Analytical chemistry, upon which all other branches of the science are ultimately dependent, has its source in the writings of the chemist-pharmacists of the iatrochemical period (1500–1700). Andreas Libavius and Otto Tachenius recognized many metals in solution together by their reactions in the wet way, but it was not until shortly before the phlogistic period (1700–1780) that any systematic progress was made, particularly by Robert Boyle, to whom we owe the term analysis. Many of the reactions still utilized in qualitative work were known to Boyle, who also introduced certain plant extracts, notably litmus, for the recognition of acids and bases. Active workers of the phlogistic period were Friedrich Hoffmann, Andreas Marggraf (who introduced the use of the microscope into chemistry), Karl Scheele and especially Torbern Bergman, who devised methods by which the metals might be separated into groups according to their behaviour with certain reagents. The blowpipe was introduced into dry qualitative analysis by the mineralogist, A. F. Cronstedt, who applied it to the examination of ores, although it was left to Jöns Berzelius and Johann Hausmann to bring about its general application. The colorations which sodium and potassium salts impart to the flame were known to Marggraf, but it is to Robert Bunsen, who, with Gustav Kirchhoff, devised spectrum analysis, that the full value of the flame test is due.

Although the work of the phlogistic period in this field was mainly of a qualitative character, some attempts of a quantitative nature were made by Marggraf and Joseph Black, while Bergman realized that elements need not be separated as such but might be isolated in the form of some suitable insoluble compounds. Martin Klaproth, who with Louis Vauquelin developed the quantitative analysis of minerals, proposed the ignition of precipitates before weighing them, if they were not decomposed thereby. Antoine Lavoisier, with his grasp of the importance of the composition by weight of chemical compounds, and because of his systematic use of the balance, must be considered as the first great exponent of quantitative analysis. The substantiation by Jeremias Richter, and independently by Joseph Proust, of the law of constant proportions and the formulation of the atomic theory by John Dalton combined to give a fresh impetus to the development of quantitative analysis, subsequently placed on a firm basis by Berzelius. The later researches of Heinrich Rose, Friedrich Wöhler and Karl Fresenius standardized various methods of analytical chemistry.

The quantitative precipitation of metals by the electric current, although known to Michael Faraday, was not applied to analytical chemistry until O. Wolcott Gibbs, in 1865, worked out the electrolytic separation of copper. Since then the subject has been extensively studied, particularly by Alexander Classen.

Volumetric analysis, possessing as it does many advantages over the gravimetric method, especially in technical work, was founded by J. L. Gay-Lussac, although rough application had been previously made; the advantages of his carefully worked out methods of chlorimetry (1824), of alkalimetry (1828) and of the chloride-silver titration (1832) were but slowly recognized. It was not until the application of potassium permanganate to the estimation of iron by F. Margueritte (1846) and of iodine and sulphurous acid to the estimation of copper and many other substances by Bunsen, that volumetric methods began to receive proper recognition. Significant contributions were made during the latter half of the 19th century, especially by K. F. Mohr and Jakob Volhard, and the subsequent development and application of these methods have been so extensive that for many purposes, particularly the control of industrial processes, gravimetric methods have been largely replaced.

Since the early part of the 20th century, there has been a rapid increase in the use of instrumental methods of analysis. Electrometric methods, especially potentiometric, have found general use as an aid to volumetric analysis. Polarographic methods involve the detection and estimation of substances by measurement of the potential and current required for partial electrolysis of the solution; usually one electrode consists of mercury dropping from a glass capillary. Coulometric methods involve a measurement of the quantity of electricity required to cause a specific reaction. Instruments based upon the use of the glass electrode in conjunction with vacuum tube amplification have largely replaced other methods for determining the effective acid concentration of solutions. Photo-electric colorimeters are used to measure the concentrations in solutions of those substances which are coloured, or which can be converted into compounds which are coloured; spectrophotometers are used to extend these measurements into the ultraviolet and infra red regions of the spectrum. The spectrograph and spectrographic methods, which depend upon the measurement of the light emitted by an element in a flame, arc or spark, have extensively replaced the use of conventional methods of qualitative analysis and are especially useful for the quantitative determination of the minor constitutents of substances.

The technique of quantitative microanalysis has been developed mainly by Fritz Pregl, although F. Emich had previously indicated the possibility of working with small amounts of

inorganic materials. The same basic principles and methods hold as for macroanalysis, but apparatus and manipulation are necessarily modified when quantities of the order of a few milligrams only are being handled. During World War II these methods were extended to microgram quantities as the result of investigations on radioactive isotopes produced in extremely small quantities in connection with atomic fission research. (*See* ULTRAMICROCHEMISTRY.)

Qualitative Inorganic Analysis.—The complete qualitative analysis of a substance in the wet way is usually preceded by certain preliminary tests made by dry methods. The results of these tests may be useful in conducting and interpreting the subsequent analysis.

Dry Methods.—1. Effect of heat: The substance when heated in a hard glass tube may char or become tarry or smoke, indicating the presence of organic matter. Since many organic compounds interfere with the analysis in the wet way, organic matter should be eliminated by a preliminary treatment with nitric acid added to sulphuric or perchloric acid.

A test for organic matter can be made in a wet way by heating the substance with concentrated sulphuric acid and noting if charring occurs.

If the substance contains water an aqueous deposit will form on the cooler part of the tube. A white sublimate is given by ammonium halide salts, mercurous chloride and bromide, oxides of arsenic; a yellow sublimate may consist of sulphur (reddish brown when molten), arsenic sulphide and mercuric iodide (turning red on rubbing). A blackish deposit results from the condensation of violet iodine vapour or of mercuric sulphide, while most mercury compounds other than those mentioned give a gray deposit.

Metallic mercury and arsenic appear as minute globules and a gray mirror.

Oxygen results from the decomposition of peroxides, chlorates, nitrates, iodates and similar oxygenated compounds, and also from oxides of the noble metals; carbon dioxide from carbonates and organic substances, usually accompanied in the latter case by charring; sulphur dioxide from many sulphides and thiosulphates. Chlorine, bromine and iodine are evolved from certain halide salts, particularly in the presence of oxidizing agents, and oxides of nitrogen from nitrates. Some cyanides evolve cyanogen or hydrocyanic acid and possibly ammonia in the presence of water. All fluosilicates (silicofluorides) are decomposed on heating, evolving silicon tetrafluoride.

2. Flame tests: When volatilized in a nonluminous flame, the compounds of certain elements cause characteristic colours. Therefore this test is carried out by introducing into the flame by means of a platinum wire a portion of the substance, preferably moistened with hydrochloric acid since the chlorides are comparatively volatile salts. Sodium gives an intense yellow coloration; potassium, violet; rubidium and caesium, bluish-violet (the latter blue when really pure); calcium, red; strontium and lithium, crimson; barium, yellowish-green; and copper, bright green; while lead, arsenic and antimony (which should not be tested on platinum) give a grayish-blue. By observing the flame through a spectroscope much more definite information can be obtained. Of the rarer metals which give flame colours, indium (blue), thallium (green), caesium and rubidium (violet) were discovered by means of the spectroscope.

3. Spectrographic analysis: The development of spectrographic equipment and methods has greatly reduced the necessity for making complete qualitative analyses in the wet way, since it is possible in many cases for a trained analyst to obtain more quickly and easily by an emission spectra analysis much of the information given by a wet analysis.

4. Blowpipe and bead tests: The substance is placed in a depression on a charcoal block and heated in the reducing flame of a blowpipe. From the changes which occur and the residue which remains, information may be obtained as to the general nature of the material. Specific information as to certain elements may be obtained by treating the residue with certain reagents such as cobalt nitrate or sodium carbonate and again heating. The colourless beads obtained by fusing borax (sodium tetraborate) or microcosmic salt (sodium ammonium monohydrogen phosphate) on a small loop of platinum wire are capable of dissolving many metallic oxides or salts, often with the production of characteristic colours; the colour may differ according as the bead is heated in an oxidizing or reducing flame. These tests are of uncertain value when applied to complex mixtures and have been largely replaced for practical use by spectrographic methods or in some cases by wet tests employing organic reagents for the identification of specific elements by the formation of coloured precipitates or soluble compounds.

Wet Methods.—1. Specific tests: A large number of so-called spot tests for individual cations and anions have been developed, especially by Fritz Feigl. The material to be tested is dissolved, a drop of the solution placed in an indentation on a white tile (spot plate), a drop of reagent solution added and the mixture examined for a characteristic precipitate or coloration; as a modification the solution to be tested may be applied to a strip of paper impregnated with reagent, or drawn into a capillary tube containing reagent. The reagent frequently contains an organic compound capable of forming intensely coloured compounds with certain elements or radicals. When applied to complex mixtures the value of these tests is limited by the fact that several constituents may give similar reactions, and that other constituents may mask or cause failure of the test.

2. Systematic analyses: Systems for the complete qualitative analysis of a material in the wet way are based upon the principle of treating a solution of the material with a succession of reagents, each reagent causing the separation of a group of constituents. The groups are then treated successively with reagents which may divide a large group into subgroups or cause the separation of the constituents singly. After being separated, a constituent may be further treated to confirm its presence or to obtain information as to the amount present. Separate portions of the material are dissolved and different procedures are used for detecting the basic (metallic or cation) and acidic (anion) constituents.

Different procedures will also be used for dissolving the material and for the subsequent analysis according to whether the material is to be analyzed for only the common basic elements or for the rarer elements as well. The solution for the analysis of the common basic constituents is prepared by first treating the material successively with water, dilute nitric or hydrochloric acids, or a mixture of these concentrated acids. Any residue is usually treated separately with hydrofluoric acid in conjunction with fuming perchloric or sulphuric acid in order to eliminate silica. A refractory residue is then fused with sodium carbonate, with or without the addition of potassium nitrate.

The fusion mass is treated with water, whereby the acidic constituents are extracted; the carbonate-oxide residue is dissolved in an acid.

Separation of the Common Basic Constituents into Groups.—Most of the various systems which have been developed employ essentially the same reagents for the major group separations; minor modifications exist in some cases where the system is designed for a semimicro scale of operation or for elementary instruction.

The first group, called the silver group, is separated by the addition of a soluble chloride, preferably ammonium chloride. The precipitate consists of silver chloride, mercurous chloride and lead chloride. The precipitation of the lead is incomplete and in some systems is prevented by proper control of conditions. The next group, called the hydrogen sulphide group, is composed of those elements whose sulphides are precipitated by hydrogen sulphide from a solution in which the hydrogen and chloride ion concentrations are approximately 0.3 molal. This precipitate contains the sulphides of copper, lead, bismuth, cadmium, mercury, arsenic, antimony and tin. If not previously precipitated by chloride, silver and mercurous mercury would become constituents of this group. This large group is subdivided by treatment with an alkaline sulphide: if a reagent composed of ammonium sulphide and polysulphide and ammonium hydroxide is used, ar-

senic, antimony and tin are dissolved and constitute the tin group; if the reagent contains sodium sulphide and hydroxide, mercury is also dissolved. The elements in the residue constitute the copper group.

By neutralizing the acid filtrate from the hydrogen sulphide group with an excess of ammonium hydroxide and adding ammonium sulphide, the ammonium sulphide group is obtained, consisting of hydroxides of chromium and aluminum, and sulphides of iron, manganese, nickel, cobalt and zinc. If phosphate is present barium, strontium, calcium or magnesium may be partly precipitated; in this case the subsequent analysis of this group is modified to separate these elements. Various methods are used for the separation of this group into subgroups. If the system is to be used primarily for elementary instruction, the precipitate may be dissolved in a mixture of nitric and hydrochloric acids, and a slight excess of ammonia added, causing the precipitation of aluminum, chromium and iron (ferric) as hydroxides. In fact, in some cases this ammonia precipitation is made and these elements separated prior to the precipitation with ammonium sulphide. More commonly the ammonium sulphide group precipitate is dissolved in acid, the resulting solution treated with an excess of sodium hydroxide together with sodium peroxide. Ferric, nickelous, cobaltic hydroxides and manganese dioxide are precipitated and constitute the iron group; the solution contains aluminate, chromate and zincate and these elements constitute the aluminum group. Two alternative procedures are in general use for the separation of what is termed the alkaline earth group. In the first of these the filtrate from the ammonium sulphide group is evaporated until it is quite concentrated in ammonium salts, then ammonium carbonate is added thus precipitating barium, strontium and calcium carbonates. Or the filtrate is evaporated to a small volume, preferably to dryness, and the ammonium salts volatilized, then a reagent of concentrated ammonia and ammonium carbonate is added, followed by ethyl alcohol; under these conditions magnesium is also precipitated. The only elements remaining in the filtrate are sodium and potassium and they constitute the alkali group. Ammonium may be considered as a constituent of this latter group but a separate sample must be used for its detection since it has been introduced in the course of the analysis.

When the analysis is made on a macro scale, the precipitates obtained are usually separated by filtration; centrifugation is more extensively used if the analysis is made on a semimicro scale.

Analysis of the Groups.—Innumerable procedures have been suggested for the separation and identification of the individual elements. The methods given below are those which have been extensively used and are representative of the general principles involved.

The Silver Group.—The group precipitate is leached with hot water to remove the lead chloride; upon addition of acetic acid and a soluble chromate to the solution the formation of yellow lead chromate identifies lead. The residue is leached with ammonia.

Mercurous chloride is converted into a black residue of mercury and mercuric amidochloride; silver chloride dissolves and is reprecipitated by acidifying the ammonia solution.

The Copper Group.—The sulphide precipitate is dissolved in nitric acid (if mercuric sulphide is present it remains as a residue), sulphuric acid is added, the solution evaporated to fuming, then diluted; this precipitates lead sulphate. The precipitate is dissolved in ammonium acetate and yellow lead chromate precipitated by addition of a soluble chromate. Addition to the sulphuric acid filtrate of an excess of ammonia precipitates white bismuth hydroxide; treatment of the precipitate with an alkaline sodium stannite solution reduces the bismuth to the black metal. If copper is present the ammoniacal filtrate is blue because of the formation of the cupric tetrammine complex; in this case cyanide is added to form the colourless cuprous tricyano complex and the solution is treated with hydrogen sulphide to precipitate yellow cadmium sulphide.

The Tin Group.—The alkaline sulphide solution is acidified thus reprecipitating the sulphides. Upon treating this precipitate with potassium hydroxide and peroxide only mercuric sulphide is left as a residue. The residue is dissolved in hydrochloric acid to which sodium chlorate is added, then addition of excess of stannous chloride precipitates white mercurous chloride which becomes gray upon further reduction to mercury. Arsenic, antimony and tin are again precipitated as sulphides and the precipitate treated with hot concentrated hydrochloric acid which leaves only the arsenic sulphide. This is dissolved by means of sodium hydroxide and peroxide and the arsenic reprecipitated as magnesium ammonium arsenate. The concentrated hydrochloric acid solution is diluted sixfold, oxalic acid is added, and the reddish-orange antimony sulphide precipitated by means of hydrogen sulphide. The oxalic and hydrochloric acids are removed from the filtrate by adding sulphuric acid and evaporating to fuming; upon diluting the solution and treating it with hydrogen sulphide yellow tin sulphide is precipitated.

The Iron Group.—The sodium hydroxide-peroxide precipitate is dissolved in nitric acid and sodium chlorate added to the hot solution; brown to black manganese dioxide is precipitated. Addition of excess ammonia to the filtrate precipitates brown ferric hydroxide. The filtrate is made slightly acid with acetic acid and potassium nitrite added; cobalt is precipitated as the yellow potassium cobaltinitrite. Upon addition of dimethylglyoxime to the filtrate precipitation of the brilliantly red voluminous nickel dimethylglyoxime results.

The Aluminum Group.—The sodium hydroxide peroxide solution is acidified, then made just alkaline with ammonia thus precipitating aluminum hydroxide. Addition of sodium carbonate and boiling the solution until the ammonia is expelled precipitates the zinc as a basic zinc carbonate. The precipitate is dissolved in hydrochloric acid, the solution made alkaline with ammonia and ammonium sulphide added; white zinc sulphide is precipitated. The sodium carbonate solution is made acid with acetic acid and lead acetate added to precipitate yellow lead chromate.

The Alkaline Earth Group.—The precipitate produced by ammonium carbonate is dissolved in acetic acid, then potassium chromate added; yellow barium chromate precipitates. By neutralizing the solution and adding alcohol, yellow strontium chromate is precipitated. Addition of ammonium oxalate to the filtrate precipitates white calcium oxalate. Magnesium, when present in this group, is precipitated as magnesium ammonium phosphate.

The Alkali Group.—The filtrate from the ammonium sulphide precipitation is evaporated to dryness, then heated until ammonium salts are volatilized; otherwise, they would interfere with the test for potassium. The residue is dissolved in water and the solution divided into two portions. To one is added sodium cobaltinitrite which causes a yellow precipitate of potassium sodium cobaltinitrite; to the other is added a magnesium uranyl acetate reagent which causes a pale yellowish precipitate of sodium magnesium uranyl acetate. A separate portion of the original material to be analyzed is tested for ammonium by heating it with sodium hydroxide; ammonia is evolved and may be detected by its odour, or by its alkaline effect on litmus paper.

Systematic Qualitative Analysis for Common and Rare Elements.—The only system including the rare elements was developed by Arthur A. Noyes and William Crowell Bray (1927). This system is characterized by the separation of groups during the preparation of the solution of the material and by the use of separations depending upon the volability or extractability by immiscible solvents of the compounds of certain elements. The complete analysis is too extended to be given and only the principal groups separation are outlined below.

The Selenium Group.—The material is distilled with concentrated hydrobromic acid whereby selenium, arsenic and germanium are volatilized as the bromides.

Silicon, Osmium and Ruthenium.—Any solid residue is treated with hydrofluoric acid to eliminate silica as the volatile silicon tetrafluoride; the solution is then distilled with perchloric acid whereby osmium tetroxide is volatilized; by addition of concentrated nitric acid to the perchloric acid and repetition of the distillation ruthenium tetroxide is volatilized.

The Tungsten, Tantalum and Gold Groups.—The residual solu-

tion from the ruthenium distillation is diluted, formic acid added and the mixture heated. The resulting precipitate contains the oxides of tungsten, molybdenum, antimony and tin, the tungsten group; the oxides of tantalum, columbium and titanium (in part), the tantalum group; also metallic gold, mercury, platinum and palladium, the gold group. The tungsten and tantalum group elements are dissolved by treating the residue with hydrofluoric acid; the solution is fumed with sulphuric acid to eliminate the hydrofluoric acid, then an excess of ammonia and ammonium sulphide added. By this treatment the tantalum group elements are reprecipitated as oxides, the tungsten group elements are dissolved as sulpho-anions.

The Thallium Group.—Hydrobromic acid is added to the formic acid filtrate thus precipitating the bromides of silver, thallium (us) and lead (incompletely).

The Hydrogen Sulphide Group.—The hydrogen-ion concentration is adjusted to three-tenths molal and the solution is treated with hydrogen sulphide; this precipitates the sulphides of tellurium, molybdenum, iridium and rhodium (the tellurium group); and lead, bismuth, copper and cadmium (the copper group). The tellurium and molybdenum are removed separately, then the copper group elements precipitated as hydroxides.

The Ammonium Sulphide Group.—Small portions of the filtrate from the hydrogen sulphide group precipitation are tested for iron and phosphate. Additional iron is added to the main filtrate and a basic acetate precipitation made by adding ammonium acetate and boiling the solution. This process causes the precipitation of chromium, aluminum, indium, zirconium, titanium, gallium and vanadium together with the iron as hydrous oxides, basic acetates, phosphates or vanadates; the precipitation of gallium and vanadium is complete only when iron is present.

The precipitate is dissolved in hydrochloric acid and the iron and gallium extracted with ether. The hydrochloric acid solution is made alkaline and excess sodium peroxide added; indium, zirconium and thorium hydroxides are precipitated and these elements constitute the zirconium group.

The filtrate from the basic acetate precipitation is made alkaline with ammonia and then ammonium sulphide added. Beryllium and the rare earth elements are precipitated as hydroxides; manganese, zinc, cobalt, nickel and uranium as sulphides. The precipitate is dissolved in acid and excess sodium hydroxide and peroxide added; manganese, cobalt and nickel (the nickel group), and the rare earth elements (the rare earth group) are precipitated as oxides or hydroxides. The two sodium hydroxide filtrates are united.

The elements present are aluminum, chromium, vanadium, beryllium and zinc (the aluminum group).

The Alkaline Earth Group.—This group is precipitated and separated as in the system of analysis for the common elements (*see* above).

The Alkali Group.—The final filtrate is analyzed for lithium, rubidium and caesium in addition to sodium and potassium.

No provision is made in the system for the radioactive elements (other than uranium and thorium), rhenium, the inert gases, nor for any elements with atomic numbers greater than 92.

The Acidic Constituents.—The analysis for the acidic constituent (the acid radicals or anions) presents a more difficult problem and is of necessity less systematic than is that for the basic constituents. This is so because not only is it necessary to detect certain acidic elements, but also to establish their oxidation state and association with oxygen or other elements. For example, if sulphur is present the analysis should not only detect it, but should determine whether it is present in the material being analyzed as elementary sulphur, sulphide, sulphite, sulphate, the numerous other sulphur oxygen acids, or in combination with other elements as in thiocyanate. In addition, many of the anions are stable only in alkaline solutions or may react one with another upon acidification. Because of these facts appropriate tests are made in order to determine if certain groups of anions are present or absent.

The preliminary tests include those for anions which (1) act as (*a*) oxidizing agents, or (*b*) reducing agents; (2) form precipitates with silver ion in (*a*) neutral, or (*b*) acid solutions; (3) form precipitates with barium ion in (*a*) neutral, or (*b*) acid solutions, and (4) form precipitates with calcium ion in ammoniacal solutions.

The solution for the analysis for the anions is usually prepared by a treatment of the material with sodium carbonate solution. This reagent has the advantage that it removes most of the metals as carbonates or oxides; otherwise they would interfere with the subsequent analysis. In the systematic analysis a portion of the sodium carbonate solution is acidified with acetic acid; sulphide and cyanide are then volatilized as hydrogen sulphide and hydrogen cyanide and are collected in an alkaline solution. Addition of perchloric acid causes the volatilization of sulphite as sulphur dioxide. Addition of cadmium nitrate causes precipitation of cadmium ferrocyanide and ferricyanide. Addition of silver nitrate to the filtrate precipitates silver iodate, iodide, thiocyanate, bromide and chloride; the iodate is separated and the last four anions constitute the halide group. In case oxidizing agents were detected by the preliminary test, sodium nitrite is added to the filtrate; this causes the reduction of chlorate and bromate to chloride and bromide and their precipitation as the silver halides. Any iodate previously precipitated is reduced and precipitated as silver iodide. The filtrate is neutralized, then made just acid with acetic acid; silver phosphate, arsenate, arsenite and oxalate are precipitated (the phosphate group). From the filtrate, sulphate is precipitated as barium sulphate, then oxalate as calcium oxalate.

Tests are made on separate portions of the sodium carbonate solution for acetate, perchlorate, nitrate, nitrite, borate, peroxysulphate and periodate. The sodium carbonate treatment of the material may leave certain acidic constituents in the residue as insoluble compounds, therefore, this residue is decomposed with zinc and sulphuric acid and additional tests made for sulphide, cyanide, phosphate, arsenate, borate and the halides. A separate portion of the material is tested for carbonate.

QUANTITATIVE INORGANIC ANALYSIS

The branch of chemistry which deals with the determination of the amount or percentage of one or more constituents of a sample is known as quantitative analysis. This field is important because of its widespread use both in research and in industrial processes; whenever chemicals are used quantitative analyses are needed. Consequently every chemist is trained in analytical methods and in their applications and limitations.

A variety of methods is utilized for quantitative analyses: in fact, almost every property of matter can be made the basis for some analytical process. For convenience these methods may be broadly classified as chemical and physical, depending upon what properties are utilized. Chemical methods are those which depend upon reactions such as precipitation, neutralization, oxidation or, in general, the formation of a new compound. Physical methods are those which involve the measurement of some physical property such as density, refractive index, absorption or polarization of light, electromotive force, production of spectra, magnetic susceptibility and numerous others. Frequently an analysis will involve a combination of chemical and physical methods, the former for separating desired constituents from a sample and the latter for measuring the amounts present.

The Analytical Balance.—The basic tool in all quantitative analyses is the analytical balance, for the accurate weighing of samples and precipitates. The balance operates on the principle of levers, the weight of an object being determined by the sum of the weights of known mass which are required to balance the object. For usual analytical work the balance should be sensitive to or determine differences in mass of 0.1 mg. (about .000003 oz.).

In microanalyses the balance is about 1,000 times more sensitive and for special work balances of even higher sensitivity have been constructed. (*See* BALANCE.)

CHEMICAL ANALYSES

The major types of strictly chemical methods are known re-

spectively as gravimetric and volumetric (or titrimetric) analyses. As the names imply, the former is based upon a measurement of the weight of a sample constituent and the latter upon the measurement of a volume of solution required to react with the sample. Application of these two methods may be illustrated by procedures which are used for the determination of chloride. In a gravimetric analysis the sample is treated with an excess of silver nitrate solution, which precipitates the chloride as silver chloride. The amount present is determined from the weight of silver chloride obtained. In a volumetric analysis the sample is treated with a solution of silver nitrate of known concentration and the volume of solution just required for reaction with all the chloride present is measured.

From this volume and the known concentration of the solution, the amount of chloride in the sample is computed.

The choice of method, gravimetric or volumetric, depends upon the conditions of the analysis. The accuracy of the two is about the same. Usually a volumetric analysis is far more rapid than a gravimetric after the necessary standard solutions are prepared. Consequently, whenever many samples are to be analyzed a volumetric method is chosen when one is available. But if only a few samples are analyzed it may be more convenient to use a gravimetric method than to prepare and standardize the solutions needed for the volumetric method.

Gravimetric Analyses.—In a gravimetric analysis the constituent sought is converted into a substance of definite composition, expressed by a chemical formula, in 100% yield. All operations in gravimetric analyses are directed toward the objectives of purity and yield. The following operations are common: (1) preparation of solution containing a known weight of the sample, (2) separation of the desired constituent in a pure condition of known composition, (3) weighing the isolated constituent, and (4) computing from the observed weight the amount of the sought constituent in the sample.

There are many methods for isolating the desired constituent from a solution of a sample. Most common is precipitation. A reagent is added which will form an insoluble compound with the desired constituent but will not precipitate other constituents of the sample. The precipitate obtained is separated by filtration, washed free of soluble impurities, dried or ignited to remove water, and weighed. Volatilization is used to separate a substance which can be readily converted into a gaseous compound. An example is the determination of carbonate in a mineral analysis. The sample is treated with an acid and carbon dioxide is evolved as a gas. The gas is absorbed in a weighed portion of an alkaline reagent and the amount of carbon dioxide is determined from the gain in weight of the absorbent. Electrodeposition is used for separation of certain metals which can be plated out by passage of an electric current through a solution. Copper in alloys is frequently determined by this method when interfering metals are not present in the sample.

(*See* ELECTROCHEMISTRY.)

The general methods of precipitation analyses are much like those of qualitative analyses (*see* section *Inorganic Analysis* above). If the sample is complex, *i.e.*, contains many constituents, it is necessary to separate the constituents into groups by successive addition of various reagents. Many of the reagents used for group separations are the same as those employed in qualitative analyses. After the groups are separated, each is redissolved and treated with specific reagents for precipitation of the constituents separately. The complete gravimetric analysis of a complex mineral may require several days, even with highly skilled operators.

The chief source of error in gravimetric analyses is in the purity of the separated constituent. In general the compounds precipitated are very insoluble and there is little error due to incompleteness of precipitation. It is a difficult matter, however, to obtain a precipitate which is 100% pure and exactly of the composition represented by a chemical formula and all gravimetric methods are subject to some degree of error because of this.

Volumetric Analyses.—In a volumetric analysis a solution of known concentration of the reagent is added to a solution of the substance to be determined until the quantity of the reagent is equivalent (*q.v.*) to the quantity of substance determined. All operations are directed toward the objective of measuring the amount of reagent equivalent to the constituent sought in the analysis. Not every chemical reaction can be utilized for volumetric procedures. The following conditions are necessary: (1) the reagent must react with only one constituent of the sample, (2) reaction must be rapid, so that each portion of reagent reacts as rapidly as added, (3) there must be some change in properties of the solution when the equivalence point is reached (usually a sudden change in concentration of ions present), and (4) an indicator (*see* INDICATORS) must be available to show the point at which equivalence is reached.

Operations of volumetric analysis are: (1) preparation of sample solution, (2) titration of sample solution with standard solution which contains a known concentration of the reagent chemical, and (3) computation of the amount of sought constituent in the sample, from the volume and concentration of reagent solution used. Titration, the determination of the amount of reagent equivalent to the sample, is done by adding the reagent slowly from a burette until the indicator shows a colour change. Ordinarily a 50 ml. burette is used and the analyst so chooses conditions that a volume of 30 to 40 ml. of reagent is required. In microchemistry the burette may have a capacity of 1 ml. or sometimes even less. Titrations are most commonly performed by use of chemical indicators, but various physical methods can also be used in special cases to show the equivalence point. A chemical indicator is a highly coloured substance which can react with one of the components of the system and show by a colour change when a component disappears or appears. A well-known example is starch, which gives with iodine an intense blue colour. If an iodine solution is being titrated the end point is marked by the disappearance of colour or conversely if iodine is the titration reagent the presence of an excess of iodine when the equivalence point is passed is marked by the appearance of blue colour.

All volumetric analyses must be preceded by standardization of the reagent solution. This is usually done by comparing the solution with a weighed sample of known purity. An acid solution, for example, is standardized by titration of a known weight of some pure basic substance such as sodium carbonate.

The determination of the amount of acid or base in a sample by titration with a standard solution of base or acid is known as neutralization. This type of volumetric analysis is widely used. Examples are the determination of the amount of free acid in vinegar or the amount of free base in lye. A variety of acid-base indicators is known. Most frequently used are phenolphthalein, methyl red and bromothymol blue. These differ among themselves in that they show colour changes at different hydrogen ion or *p*H values. In an acid-base titration it is important to select that indicator whose colour change corresponds to the hydrogen ion concentration of the equivalence point; use of the wrong indicator might lead to erroneous results.

Scores of volumetric methods are based upon oxidation-reduction reactions, in which there is a change in valence of some ion. A familiar example is the determination of iron by titration with permanganate or ceric sulphate solution. Prior to this determination it is necessary to reduce all the iron to the ferrous (Fe^{++}) condition and to remove from the solution all other reducing agents which might react with the standard solution of oxidizing agent. In the titration iron is oxidized to the ferric condition (Fe^{+++}). The amount present is computed from the volume of oxidizing agent required to react with the iron. If the standard solution used is potassium permanganate no indicator is required for the titration. Permanganate ion is so highly coloured that when the equivalence point is passed a drop or two of solution in excess will impart colour to the solution, thereby giving the end point. Oxidation indicators are known which can also be used. These are substances which are less readily oxidized than ferrous ion and consequently they are not affected until the equivalence point is reached and all the ferrous ion has been oxidized. At this point the indicator is oxidized and shows by a colour change that the end point is reached.

The most widely used standard oxidizing agents in mid-20th

century were potassium permanganate and ceric sulphate. Both of these are strong oxidizers and can be used to titrate numerous reducing agents, such as iron, titanium, vanadium, uranium, sulphides, nitrites, sulphites, oxalates, hydrogen peroxide, arsenic, antimony, molybdenum and many others, after a suitable solution of the sample is prepared with the sought constituent in its lower valence state. Another important class of oxidation-reduction (frequently called redox) determinations involves iodine. When potassium iodide is treated with any strong oxidizing agent iodine is liberated in equivalent amount. Titration of the liberated iodine gives an indirect measure of the amount of oxidizing agent which reacted with the potassium iodide. Thus this method can be used for analysis of any oxidizing agent which liberates iodine from potassium iodide.

The standard solution used to titrate the iodine may be either sodium thiosulphate or arsenious oxide.

Precipitation reactions can often be used for volumetric analyses when an indicator is available to show when the equivalence point is reached. A common example is the determination of chloride by titration with silver nitrate solution, as described above.

There are numerous substances for which there are no good volumetric methods. Examples are ions which are not readily oxidized or reduced and which do not give precipitates suitable for utilization in volumetric analyses, such as sodium, potassium, calcium, aluminum, etc. For some of these it is possible to devise an indirect method of volumetric analysis. Calcium for example can be determined volumetrically by first precipitating it as calcium oxalate, then dissolving the precipitate in sulphuric acid and determining oxalate by titration with potassium permanganate. Since the amounts of calcium and oxalate in the precipitate are equivalent the titration gives the equivalents of calcium in the sample.

Other Chemical Methods.—Some other chemical and physicochemical methods of less frequent use than gravimetric and volumetric analyses are listed below:

Colorimetric analyses are based upon the absorption of light by coloured substances in solution. They can be used when the sought constituent can be converted by chemical reaction into a coloured compound, in absence of other coloured compounds in the solution

Nephelometric analyses are based upon the amount of turbidity in a solution and the effect of this turbidity upon the transmission of light.

This method is applicable only to the determination of small amounts of substances which yield a precipitate when treated with certain reagents.

Gas analysis depends upon selective absorption of constituents in a gaseous mixture and measurement of the changes in volume which occur when absorption has taken place. Prior to absorption carbon compounds are burned in excess oxygen, yielding carbon dioxide and water.

Fire assay is used to determine the amounts of precious metals in ores. The ore samples are heated with a flux and the metals are reduced to the free state. The free metals are then extracted from the flux by molten lead, which on cooling retains the precious metals as an alloy.

The amounts of precious metals are determined by dissolving (parting) the lead button in acids followed by chemical analysis of the solution or of the residue of metals which do not dissolve.

Computations of Chemical Analyses.—The basis for all quantitative computations is the weight relations expressed by a chemical equation. The equation

$$2NaOH + H_2SO_4 = Na_2SO_4 + 2H_2O$$

shows that two molecules of sodium hydroxide react with one molecule of sulphuric acid to give one molecule of sodium sulphate and two molecules of water. Since a molecule of sodium hydroxide weighs 40.00 atomic weight units (the sum of the atomic weights of Na, H and O) and a molecule of sulphuric acid 98.08 units then 2 × 40.00 units of NaOH react with 98.08 units of H_2SO_4 (*see* ATOM: *Atomic Weights*). The ratio of weights of NaOH and H_2SO_4 reacting are the same regardless of the units employed, whether these be grams, ounces, tons, etc.

In gravimetric analysis one computes from the weight of a precipitate the corresponding weight of the sought constituent by use of a factor based upon the atomic weights. Thus, from the weight of AgCl precipitate the weight of Cl is computed by the relation

$$\text{Weight Cl} = \text{Weight AgCl} \times \frac{\text{atomic weight Cl}}{\text{sum of atomic weights of Ag and Cl}}$$

In volumetric analyses the computations involve the volume and concentration of the reagent solution. The unit of concentration is conveniently chosen as the equivalent weight (*see* EQUIVALENT) and a solution which contains one equivalent weight of solute per liter is known as a 1 normal (1N) solution. Since titrations are made to the point that the equivalents of reagent equal the equivalents of sample, it follows from the definitions that the product, volume of reagent in liters times the normality of the reagent, is the total equivalents of reagent and therefore the total equivalents of the sought constituent in the sample. Multiplication of this value by the weight of one equivalent gives the weight of the sample constituent in grams. For example, if titration of a Cl sample requires 40.00 ml. 0.1N $AgNO_3$ solution, the weight of Cl in the sample is

$$\underset{\text{(vol. in liters)}}{40.00/1{,}000} \times \underset{\text{(normality)}}{0.1} \times \underset{\text{(eq.wt. Cl)}}{35.46} = \text{grams Cl}$$

Physical Methods.—As mentioned above, the variety of physical properties which can be used for analytical purposes is almost endless.

Only the more important physical methods of analysis can be mentioned here.

Spectrochemical.—The application of optical emission spectra to quantitative analyses was so well established by mid-20th century that in many control laboratories it had supplanted chemical analyses for numerous constituents. This was particularly true in the analysis of alloys for minor constituents. The basis for the method is the fact that the intensity of spectral lines (*see* SPECTROSCOPY) can be related to the concentration of the emitting element in the sample. Requirements are a spectroscope of sufficient dispersion in both the visible and the ultra-violet regions and a microphotometer for measurement of the blackness or density of the spectral line.

Before a spectrochemical method can be used it is necessary to work out curves relating line densities to concentrations, based upon samples of the general composition of those to be analyzed. This preliminary preparation of the working curve is based upon chemical analyses of the standard samples. It may require weeks of careful work to standardize conditions and develop the working curve for a given analysis. Consequently the spectrochemical method is not well suited to the analysis of occasional samples but it finds best application in routine analyses where large numbers of samples must be processed. Once methods are developed the spectrographic procedure is very rapid and accurate. It is possible to take molten metal samples from a furnace and to obtain an analysis for several constituents within 8 to 15 min. after the sample is withdrawn; this speed is far beyond that of any other method.

Light Absorption.—Colorimetry as described above has been in use many years for coloured substances. Recently this general method has been further developed and extended by spectrophotometry which is the measurement of the transmission of ultra-violet, visible and infra-red light of selected wave lengths. The spectrophotometer is an instrument arranged to give a light beam of a selected wave length range and to measure the fraction of this light absorbed by a sample solution. Many materials which are colourless in visible light, due to complete transmission of all components, will absorb strongly and selectively in the ultra-violet and infra-red regions. The analysis of solutions which contain such substances is based upon determination of the transmission curve and the quantitative measurement of the fraction of light absorbed at various wave lengths.

(*See* PHOTOMETRY.)

Polarimetry.—Polarimetry, or the measurement of rotation

of polarized light has been used as an analytical method many years. An example is the analysis of sugar solutions whose concentrations can be read directly from the graduations on the scale of a special polarimeter.

Refractive Index.—Refractive index is often used to identify organic compounds and to measure the concentrations of solutions. A useful application is in the determination of the alcoholic content of beverages. Alcohol is distilled from the sample and collected in a measured volume of water. From the refractive index of the resulting solution the alcoholic content of the original sample is readily computed.

Polarograph.—This is an instrument arranged to trace a current-voltage curve during electrolysis of a solution at a dropping mercury electrode. S-shaped curves are obtained whose position on the voltage co-ordinate is characteristic of the material in solution and whose amplitude is proportional to the concentration.

The instrument has had extensive use in many analytical problems, particularly for the determination of small amounts.

***p*H Meters.**—The continuous and accurate determination of hydrogen-ion concentrations is important in many manufacturing processes. To facilitate this there have been developed many types of *p*H meters so arranged that the hydrogen-ion concentration is related to the voltage reading of the meter. By a slight modification these instruments can be used to detect potentiometrically the end point in oxidation-reduction and in certain precipitation titrations.

(*See* HYDROGEN-ION CONCENTRATION.)

X-ray Diffraction.—The characteristic X-ray diffraction pattern given by crystalline substances can be made the basis for qualitative and quantitative analyses where other methods are lacking. A beam of monochromatic X-rays is passed through a small tube of the powdered sample and the diffracted lines detected by their effect upon a photographic plate or film. The position of the lines serves to identify the crystalline species present and quantitative measurements of amounts present can be made by the intensity of the lines.

ULTIMATE ORGANIC ANALYSIS

The limited number of elements (carbon, hydrogen, oxygen, nitrogen, sulphur, halogens and occasionally phosphorus and some metals) employed by nature in building up her vast store of organic compounds would suggest that the analyses of such substances are simple operations, and this is true in so far as the determination of the elements present, their relative proportions, and the molecular complexity of the compound are concerned. Naturally such information tells us nothing of the *structure* of the compound and, indeed, leaves us much in the same position as we should be in if we were interested in some building and were supplied with the builder's estimate for material while denied access to the architect's drawings and plans. The problem of determining the manner in which the elements present in organic compounds are arranged, important as it is, lies outside the scope of the present article, which is limited to the description of the ultimate analysis. With the exception of oxygen, all the elements present in organic compounds can be estimated readily; oxygen is nearly always determined by difference, and in view of this fact it is of great importance that a careful qualitative examination be made of a substance, otherwise the results of the quantitative analysis may be interpreted erroneously.

Qualitative Tests for the Elements.—*Carbon and Hydrogen.*—The organic nature of a compound is generally indicated by its behaviour on being heated in air; solids usually melt, then burn with a more or less smoky flame, leaving a black residue of carbon. To test directly for carbon and hydrogen, a small quantity of the material intimately mixed with about 20 times its bulk of dry copper oxide powder is heated in a dry test tube closed by a cork carrying a delivery tube which dips into a solution of limewater. The copper oxide is reduced, the hydrogen is converted to water which bedews the cool part of the tube, and the carbon oxidized to carbon dioxide which forms a precipitate of chalk in the limewater.

Nitrogen, Halogens, Sulphur.—When organic compounds containing any or all of these elements are heated strongly with metallic sodium they are decomposed with the formation of sodium cyanide, halide and sulphide, respectively (Lassaigne's test). To test for these elements, therefore, 1 mg. of the substance and a small pellet of sodium (or potassium) are heated in a narrow test tube, gently at first and afterward more strongly, until the glass softens; the hot tube is shattered by plunging it into water, which converts any residual sodium into sodium hydroxide, yielding an alkaline solution of the sodium salts, which is boiled and filtered, and the filtrate is used in the following tests:

1. Nitrogen.—A portion of the filtrate is mixed with a solution of ferrous sulphate containing a small quantity of the ferric salt and boiled, thereby converting any sodium cyanide present to ferrocyanide, which gives a bluish-green solution and a precipitate of Prussian blue on adding hydrochloric acid.

2. Halogens.—A second portion of the alkaline filtrate is acidified with nitric acid and silver nitrate added, any precipitate of chloride, bromide or iodide, or a mixture of these, is examined in the usual manner. If the original substance also contains nitrogen or sulphur, the acid solution must be boiled to expel the hydrogen cyanide or hydrogen sulphide before adding the silver nitrate.

3. Sulphur.—A third portion of the alkaline filtrate is tested for sodium sulphide (1) by the formation of a deep violet colour when treated with a few drops of a freshly prepared solution of sodium nitroprusside; (2) by the evolution of sulphuretted hydrogen when acidified—this is readily detected by the odour and also by lead acetate test paper.

Phosphorus.—A small portion of the organic compound is intimately mixed with about ten times its bulk of a mixture of sodium carbonate and peroxide (2:3) and heated to fusion in a nickel crucible. The cold water extract of the melt is filtered, acidified with nitric acid, and tested for phosphoric acid with ammonium molybdate.

Metals.—(1) Volatile metals. (*a*) Arsenic.—The presence of arsenic in an organic compound is usually revealed by the formation of a dull gray mirror of the metal on the walls of the test-tube when the compound is fused with sodium as in Lassaigne's test. (*b*) Arsenic and Antimony.—A small quantity of the compound is fused with a mixture of sodium carbonate and peroxide as in the test for phosphorus. The fused melt is extracted with water, acidified and tested with sulphuretted hydrogen. (*c*) Mercury.—When an organic compound containing mercury is mixed with soda lime and heated in a long test tube, a mirror of metallic mercury is formed.

(2) Nonvolatile Metals.—Any of these metals that may occur in organic compounds are found as such or in the form of their carbonate or oxide in the ash left after the compound has been ignited on porcelain or silica. The ash is dissolved in dilute hydrochloric acid and the solution examined for metals in the usual manner.

Quantitative Analysis of Organic Compounds.—*Estimation of Carbon and Hydrogen.*—The carbon and hydrogen in an organic compound are estimated by completely oxidizing a weighed quantity of the substance and weighing the carbon dioxide and water thus formed. The simple method devised by Liebig in 1831 for carrying out this operation is in all essential principles the one still employed. A weighed quantity of the substance is heated in a tube filled with dry copper oxide, and the water and carbon dioxide are absorbed in weighed tubes filled with dried calcium chloride and potassium hydroxide solution or soda lime respectively. A current of dry air or oxygen is passed through the tube to sweep the products of combustion into the absorption apparatus. Fig. 4 shows the essential details of the apparatus required for these estimations; *a* and *b* are closely fitting, short

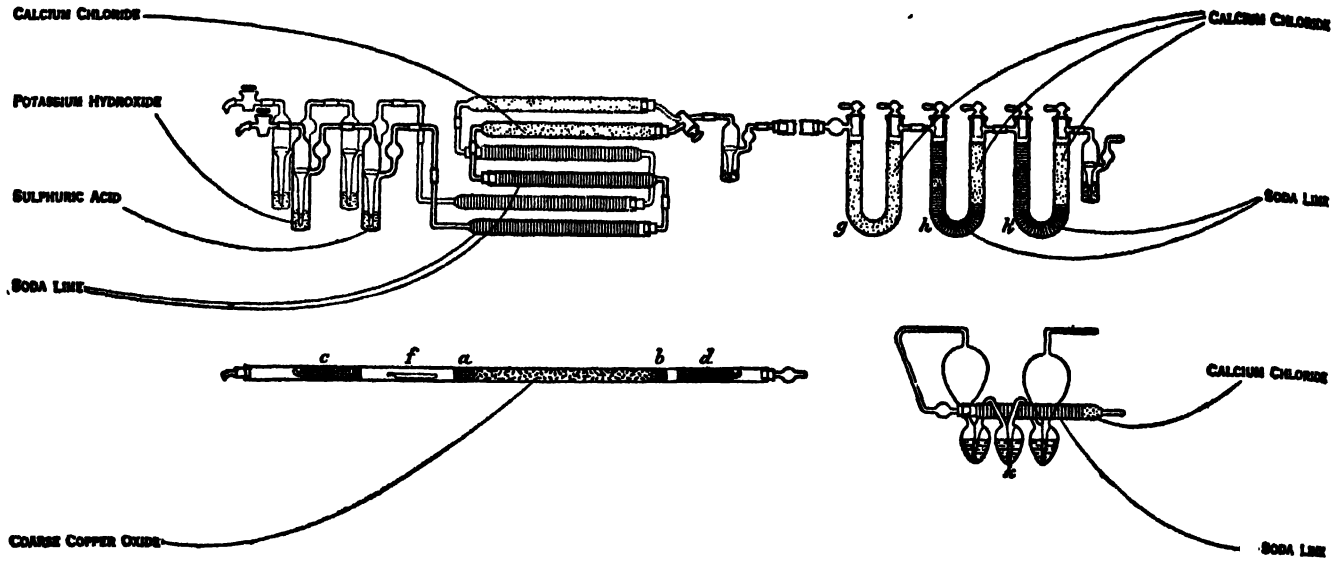

FIG. 4.—APPARATUS FOR QUANTITATIVE ESTIMATION OF CARBON AND HYDROGEN IN AN ORGANIC COMPOUND
THE PRINCIPLE DEPENDS ON OXIDIZING A WEIGHED QUANTITY OF THE COMPOUND AND THEN WEIGHING THE RESULTANT DIOXIDE AND WATER

spirals of copper gauze which serve to hold the copper oxide in position; the copper oxide is prepared by oxidizing copper wire; *c* and *d* are longer copper oxide spirals; *f* is the platinum or porcelain boat containing the weighed quantity of the compound.

In the absorption apparatus, the water is collected in the glass stoppered U-tube *g*, filled with calcium chloride (carefully freed from lime). The carbon dioxide is absorbed by the soda lime contained in the U-tubes *h* and h^1, the second limb of each tube containing a short filling of calcium chloride. The two soda lime tubes may be replaced by the apparatus *k*, of which the bulbs are charged with concentrated potassium hydroxide solution and the side tube filled with soda lime and calcium chloride. The apparatus for purifying the current of air or oxygen is connected with the anterior end of the tube and consists of a series of washing cylinders charged with potassium hydroxide or sulphuric acid, and U-tubes filled with soda lime or calcium chloride to remove moisture and carbon dioxide from the incoming gas. This apparatus is arranged in duplicate, one for the air and one for the oxygen supply. Any simple form of gas-heated furnace may be employed (fig. 5), or the tube may be heated electrically.

The combustion tube and its copper oxide charge are dried by heating the tube to a dull red heat for about an hour while a current of dry air is passed, the posterior end of the tube being protected by a calcium chloride tube. At the end of that time the fore part of the tube containing the oxidized spiral and the first six inches of copper oxide is cooled. While this process is in operation, the weighings are made. About 0.2 g. of the pure dry compound to be analyzed is weighed into the platinum or porcelain boat if the compound is a solid or a nonvolatile liquid. Volatile liquids are weighed in small thin glass bulbs drawn out to a capillary opening. The tubes for collecting the water and carbon dioxide are also weighed, and attached to the posterior end of the combustion tube. The boat and its contents are then introduced into the cooled anterior end of the combustion tube.

A slow current of air is passed through the tube, and the burners under the oxidized spiral in the rear of the boat are lighted. The heating is gradually extended toward the boat by moving forward the heated screen over the tube, or increasing the flame surface under the tube, the object being to distil the contents of the boat, or the volatile products of decomposition, on to the cold copper oxide where the combustion is completed. This most critical part of the operation must be carried out very slowly, and is finally completed in a current of oxygen which burns any residue of carbon left in the boat, and reoxidizes the reduced copper oxide. After displacing by air the oxygen in the apparatus, the absorption tubes are removed, closed, cleaned and allowed to cool in the balance room before being reweighed. From the weight of carbon dioxide and water yielded by the definite weight of the compound, the percentages of carbon and hydrogen in the compound are readily calculated.

The simple method described above applies to compounds containing carbon, hydrogen and oxygen only; if elements other than these are present the filling of the tube must be modified as follows: (*a*) *Nitrogen present.* The copper oxide spiral (*d*) is replaced by a similar spiral of freshly reduced copper to reduce any oxides of nitrogen that may be formed during the combustion. It is introduced into the end of the tube that has been previously cooled, before attaching the absorption apparatus. (*b*) *Halogens, sulphur or arsenic present.* The first six inches of copper oxide after the boat are replaced by a lead chromate cartridge, made by filling a hollow cylinder of copper gauze with freshly ignited fused lead chromate. The copper container becomes oxidized in the preliminary heating of the tube, nonvolatile lead compounds being formed with the sulphur or arsenic in the compound, and sparingly volatile compounds with the halogens. A short spiral of silver gauze should, therefore, be introduced at the posterior end of the tube when the compound contains halogens.

Estimation of Nitrogen.—The two methods in use for the estimation of nitrogen are (*a*) the absolute method (Dumas), in which the nitrogen in a known weight of the compound is eliminated in the gaseous form and estimated by direct measurement; (*b*) the Kjeldahl method, in which the nitrogen in a known weight of the material is reduced to ammonia and estimated volumetrically by titration. (*a*) The absolute method consists in the complete oxidation of a known weight of the compound by heating it with copper oxide in a tube in a current of carbon dioxide, passing the gaseous products of combustion over a heated copper spiral and collecting the nitrogen in a gas burette over strong potassium hydroxide solution. The gas is afterward transferred to a calibrated eudiometer tube and measured over water. The method of filling the tube is indicated in fig. 5. The three grades of coarseness in the copper oxide used are obtained by crushing the ordinary copper oxide made from wire, and passing it through two copper gauze sieves, 20 strands and seven strands to the centimetre respectively; the first retains the coarse and medium grades, and the second the coarse. The amount of the substance used in an analysis should be sufficient to give about 20 c.c. of nitrogen. The charged tube is placed in the furnace and connected with an apparatus for generating carbon dioxide and with a Schiff's nitrometer filled with a concentrated solution of potassium hydroxide. While the air in the apparatus is being displaced by carbon dioxide, the part of the tube containing the coarse copper oxide and reduced spiral is heated to dull redness. When no

insoluble gas collects in the charged nitrometer, the current of carbon dioxide is stopped, and the nitrometer is filled with the potassium hydroxide solution which is allowed to overflow into the thistle funnel seal attached to the end of the capillary transferring tube. The burners under the copper oxide spiral are then lighted, and when this part of the tube is at a dull red heat, the heating is extended toward the mixture of the substance with copper oxide, and so regulated that not more than three bubbles of gas are ascending the nitrometer tube at the same time. Finally, when all the burners are lighted, the tube has attained a uniform dull red heat, and there is no further evolution of gas, a slow current of carbon dioxide is again passed through the tube to sweep out the remainder of the nitrogen. The nitrometer is then removed, the gas reduced to atmospheric pressure, by bringing the liquid in the open arm of the nitrometer to the same level as that in the closed arm, and after about 15 minutes transferred to a eudiometer tube over boiled-out water, which is then completely immersed in a tall glass cylinder of water containing also a thermometer. After about ten minutes the volume of the nitrogen (v) the temperature (t) and the barometer (p) are read. If p' is the tension of aqueous vapour under these conditions and w denotes the weight of substance taken, the percentage of nitrogen in the compound is given by the expression

$$\frac{\times (p-p') \times 0.12507}{(273+t) \times 760}$$

(*b*) The Kjeldahl method is a modification of Will and Varrentrapp's method and is used for the estimation of nitrogen in such materials as foodstuffs, therapeutic substances, fertilizers, etc., in which the amount of nitrogen is small and many determinations have to be carried out simultaneously and rapidly. The method consists in decomposing the organic material by heating it with concentrated sulphuric acid; the carbon is oxidized and the nitrogen converted to ammonia which is retained as the sulphate, and afterward estimated in the usual manner by distillation (*see* AMMONIA). A weighed quantity of the material (0.5 to 5.0 g.) is placed in a long-necked, pear-shaped flask of 500 c.c. capacity, 20 c.c. of concentrated sulphuric acid are added, the flask is clamped in an inclined position and the contents heated gradually to avoid frothing. After the acid has been boiling for about 15 minutes, 10 g. of potassium sulphate are added, and the heating is continued until the contents of the flask are clear and a faint straw colour. In cases of not easily oxidizable materials, small quantities of certain metallic salts such as copper or mercuric sulphate or mercurous iodide may be added. Finally the cold acid liquid is transferred, with the washings of the flask, into the distilling flask of an ammonia distillation apparatus; after the contents of the flask have been made alkaline, the ammonia is distilled into a measured volume of standard sulphuric acid and estimated by titrating the excess of acid.

The Kjeldahl method can also be applied to the analysis of pure organic compounds, provided that those compounds which contain nitrogen combined directly with oxygen or with nitrogen as in nitro-, nitroso-, azo- or diazo-compounds or hydrazines, undergo a preliminary reducing operation.

Estimation of Halogens.—The estimation of halogens involves the complete decomposition of the compound, with the conversion of the halogen element into the hydracid or one of its salts, which is subsequently precipitated and estimated as the silver salt. (*a*) Liebig's is the oldest method and the one applicable to the largest number of organic compounds. It consists in decomposing a weighed quantity of the compound by heating it to redness with a large excess of pure lime in a glass tube sealed at one end, plunging the hot tube into cold water, dissolving the lime and calcium halide in cold dilute nitric acid, filtering, and estimating the halogen acid in the filtrate in the usual manner. Piria and Schiff modified the method in the direction of shortening the time of the operation, by replacing the lime by a mixture of lime and sodium carbonate, and the glass tube by two nickel crucibles, the smaller one containing the mixture of the substance being inverted in the larger, and the annular space between the two filled with the lime and sodium carbonate mixture. (*b*) Stepanoff's method, as modified by Bacon, is applicable to compounds in which the halogen is readily eliminated as hydracid by hydrolysis or by reduction. It consists in heating a weighed quantity of the compound with sodium and alcohol, and estimating the sodium halide in the resulting solution. (*c*) The method of Carius, as modified by Kuster, is the one most generally employed; it consists in the destructive oxidation of a weighed quantity of the compound (about 0.2 g.) by means of fuming nitric acid (2 c.c.) in the presence of silver nitrate in a sealed tube at a temperature of 250°–270° C.

The halogen is converted into the silver salt and is weighed as such.

Estimation of Sulphur.—The estimation of sulphur in organic compounds involves the destructive oxidation of the substance whereby the sulphur is converted to sulphuric acid and weighed as the barium salt. The two methods in general use are:—(*a*) The method of Carius, in which the operation is carried out as in the preceding case, no silver nitrate is required, but as the oxida-

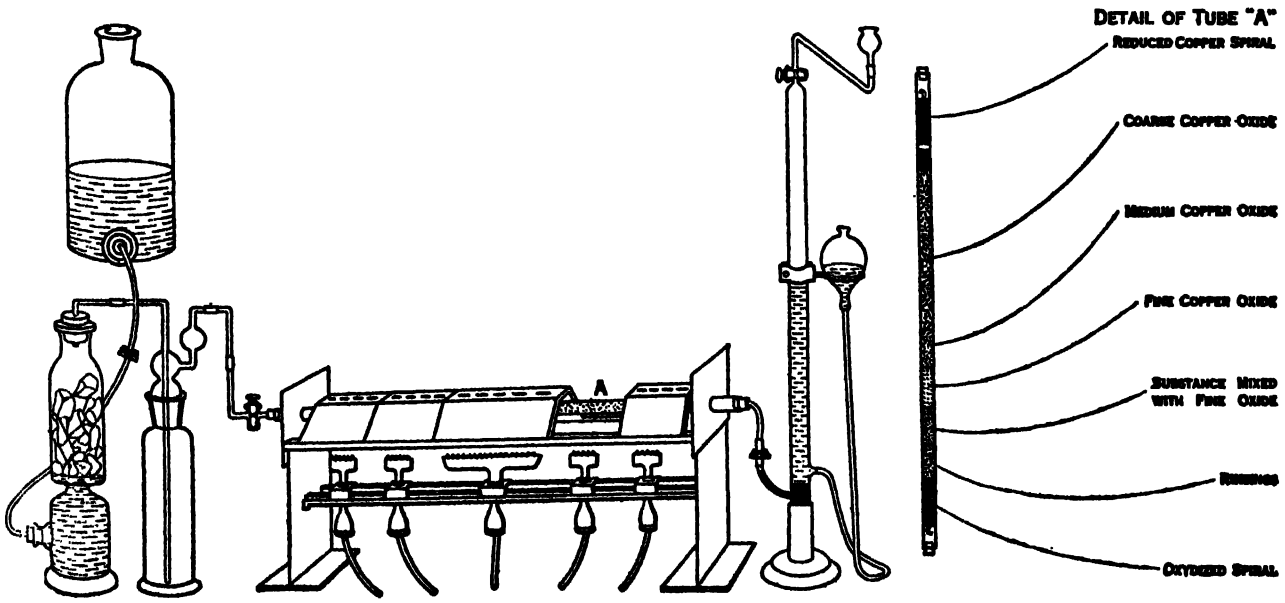

FIG. 8.—APPARATUS FOR ABSOLUTE METHOD (DUMAS) OF ESTIMATION OF NITROGEN IN AN ORGANIC COMPOUND
A KNOWN WEIGHT OF THE COMPOUND IS HEATED WITH COPPER OXIDE IN A CURRENT OF CARBON DIOXIDE; THE NITROGEN EVOLVED IS COLLECTED OVER A STRONG SOLUTION OF POTASSIUM HYDROXIDE AND THEN MEASURED IN A EUDIOMETER TUBE

tion is facilitated by the presence of a small quantity of bromine, a crystal of potassium bromide is placed in the tube containing the compound. The contents of the tube are diluted with water, the nitric acid removed by evaporation and the sulphuric acid precipitated and weighed as the barium salt. (*b*) The method of Asboth, in which the oxidizing agent employed is a mixture of sodium peroxide (three parts) and sodium carbonate (two parts). A weighed quantity of the substance (0.2 to 0.5 g.) is mixed with about 15 g. of the oxidizing mixture in a nickel crucible which is then carefully heated until the contents become liquid. When cold, the melt is extracted with water, and the soluble sulphate estimated in the usual manner.

Estimation of Phosphorus.—Organic compounds containing phosphorus are oxidized by fuming nitric acid, by concentrated nitric acid and potassium permanganate, or by chromic and sulphuric acids. The resulting phosphoric acid is precipitated as ammonium phosphomolybdate, and subsequently weighed as magnesium pyrophosphate.

Estimation of Metals in the Salts of Organic Acids and Bases. Gold, silver and platinum in organic salts are weighed as the metallic residue left after the organic material has been destroyed by igniting a weighed quantity of the dry salt in a platinum or silver crucible. Sodium, potassium, barium and calcium salts are decomposed by igniting a weighed quantity of the dry salt in the presence of pure sulphuric acid and weighing the sulphate of the metal.

Modern Modifications.—The methods described for the ultimate analysis of organic compounds leave nothing to be desired on the score of simplicity and accuracy, but many of them are very tedious in operation, and the modifications that have been introduced aim at reducing the time required for the analysis. The earlier attempts were directed toward the employment of more vigorous oxidizing agents than copper oxide, and of these the use of oxygen in the presence of a contact substance (Kopfer, 1876) has been employed with singular success by Dennstedt. He uses a platinum contact material, heated to bright redness, and passes the vapour of the substance over it in a rapid stream of oxygen. The carbon dioxide and water are collected and weighed in the usual manner. If the compound contains nitrogen, chlorine, bromine or sulphur, a boat containing lead peroxide heated to 320° C. is placed in the rear part of the combustion tube; this serves to break up any oxides of nitrogen that may be formed, and at the same time to absorb quantitatively the chlorine, bromine or sulphur, which can be estimated subsequently by the usual gravimetric methods. If iodine be present this can be retained by molecular silver contained in a second boat placed in the rear of the first.

Later modifications have aimed at reducing the time required for a combustion by a corresponding reduction in the amount of material analyzed and the magnitude of the apparatus employed, and the microanalytical methods devised by Pregl, Dubsky, Funk and others are now fairly extensively employed in schools of organic research.

Using 5–15 mg. of the substance, a carbon and hydrogen estimation can be completed within an hour.

H. ter Meulen and his school have recently described new methods for the ultimate analyses of organic compounds which include the direct estimation of oxygen. The analyses are carried out by the combustion (oxidation), or the destructive hydrogenation method, usually with the help of catalysts. The operations can be conducted with great rapidity, as about 50 mg. of the compound are employed in each estimation, and many of the final operations are volumetric instead of gravimetric. Thus nitrogen is reduced quantitatively to ammonia and estimated by titration; the halogens are reduced by hydrogen containing ammonia to the ammonium halide and estimated volumetrically by the Volhard method.

GAS ANALYSIS

The field of gas analysis in a broad sense embraces the sampling and determination of all types of gaseous substances. The purpose of such analyses are many and varied. The following are a few typical examples: (1) evaluation of toxicity hazard of a particular gas, such as carbon monoxide in a vehicular tunnel; (2) determination of the composition of (a) fuel gases to ascertain heating value or for control of plant operations, (b) flue gases to evaluate efficiency of combustion, (c) exhaust gases from internal-combustion engines to establish proper carburettor adjustment for maximum efficiency, and (d) mine gases to evaluate explosion hazard and quality of air; and (3) determination of products of combustion of various types of materials to ascertain toxic constituents formed.

Numerous procedures and many types of specialized equipment have been developed for the determination of the various kinds of gases which occur under widely different conditions. The methods in general are based on chemical reactions or measurement of some specific property by physicochemical means.

The chemical reaction most commonly used is absorption of a specific gaseous constituent in a suitable liquid absorbent. The amount of gas present may then be estimated by (1) measuring the reduction in the volume of the sample due to absorption of the constituent, (2) titration of the absorbed gas with suitable reagent as acidimetric or iodometric determinations, (3) colorimetric comparison with standards, and (4) weighing of a precipitate such as barium carbonate.

Physicochemical measurements are made with such instruments as the interferometer, thermal conductivity apparatus, infra-red absorption spectrograph, mass spectrograph, combustible gas indicator, and many other indicators and recorders usually designed for the determination of a single gas.

This discussion is confined to typical conventional gas analysis methods and does not include discussion of such apparatus as the Van Slyke, Warburg-Barcroft and other specialized equipment which has been developed for a particular application or field of work as gas analysis in biological investigations.

Gas Volumetric Methods.—Virtually all conventional gas-analysis methods are based on the successive absorption of some constituents with suitable absorbents and combustion of other constituents. The volume of each gas removed is then determined by (1) measuring the change in volume at constant pressure and temperature or (2) measuring change in pressure at constant volume and temperature.

Apparatus used in the United States is designed to measure change in volume, whereas in England change in pressure is more commonly measured.

The Van Slyke apparatus used for determination of blood gases is also based on the principle of measuring change in pressure.

Two basic procedures are used to absorb the gases, one in which the absorbent is confined in a vessel or pipette into which the gas is passed for absorption, and the other in which the absorbent is added to the gas in the burette or auxiliary vessel. The absorbent in the pipette is used to analyze a number of samples, whereas the absorbent added to the burette or auxiliary vessel is used only once.

The Hempel, Orsat, and Haldane apparatus are examples of the former, and the Elliott and Morehead are examples of the latter. In the Hempel apparatus the burette and pipette are separate. The appropriate pipette is connected to the burette for each specific constituent.

In the Orsat and Haldane apparatus a series of pipettes is securely attached to the burette through a manifold to make an integral unit.

As a discussion of all types and modifications of apparatus which have been designed utilizing these principles would be too voluminous, only typical examples are described.

Orsat Type of Gas-Analysis Apparatus.—The Orsat type of gas-analysis apparatus is more commonly used than any other. It is designed for various applications that range from small compact portable types with only one or two pipettes to large laboratory models having a half dozen or more pipettes.

The Orsat type of gas analysis apparatus (*see* fig. 6) consists essentially of: (1) burette, (2) pipettes, (3) copper oxide tube, (4) confining liquid, (5) compensator tube and (6) a water jacket for the burette and compensator tube. The burette is a cylindrical glass tube of 100 ml. capacity with carefully calibrated graduation marks to permit reading of gas volumes to a fraction of a milliliter. The burette is closed at the top with a stopcock, and the bottom is connected by a rubber hose to a reservoir for the confining liquid. The confining liquid may be water, a salt solution or mercury. As gases may dissolve in water or aqueous solutions, mercury is preferred and usually is employed in laboratory apparatus. Acid water or salt solutions are usually employed in portable units. The number and type of pipettes depend on the type of work to be done, but laboratory models usually have pipettes for the removal of carbon dioxide, illuminants, oxygen, carbon monoxide and for slow combustion of methane and ethane. The copper oxide tube is for the oxidation of carbon monoxide and hydrogen. The confining liquid not only confines the gas in the burette but also serves to draw the sample into the burette and forces it into the pipettes or copper oxide tube as required. Since the results of the analyses are based on change in volume due to absorption or combustion, it is essential that no changes in volume of sample occur due to changes in temperature, atmospheric pressure or water vapour. The water jacket surrounding the burette and compensator tube serves to control the temperature. Changes in pressure and water-vapour content due to slight changes in temperature are controlled by the compensator and by having a small amount of water on the mercury in the burette and in the compensator tube.

Analysis of Fuel Gas.—The use of the Orsat-type gas-analysis apparatus for the analysis of a fuel gas offers a typical example of the application and technique of gas analysis. The analysis of a fuel gas may require determination of the following constituents: carbon dioxide, illuminants, oxygen, carbon monoxide, hydrogen, methane, ethane and inert gases, mainly nitrogen. Illuminants include a number of unsaturated hydrocarbons, such as ethylene, propylene, butylene, benzene, toluene and acetylene.

Since the constituents are removed one at a time it is necessary that the absorbent used for the first constituent does not remove any of the other components. In other words, the order of removal of constituents is important and is fixed by the reagents used.

The following is the order in which the gases are usually determined and the reagents or reactions which are commonly used for the determination of the various gases:

(1) Carbon dioxide	Absorbed with potassium hydroxide
(2) Illuminants	Absorbed with fuming sulphuric acid
(3) Oxygen	Absorbed with alkaline pyrogallate
(4) Carbon monoxide	Absorbed with acid or ammoniacal cuprous chloride and cuprous sulphate-beta naphthol. Also determined by oxidation with heated copper oxide or by slow combustion with heated platinum spiral
(5) Hydrogen	Determined by oxidation with heated copper oxide or by slow combustion with oxygen
(6) Methane	Determined by slow combustion with oxygen
(7) Ethane	Determined by slow combustion with oxygen
(8) Nitrogen and other inert gases	Estimated by difference. Not determined directly

The potassium hydroxide solution is prepared by dissolving 30 g. of KOH in 100 ml. of distilled water. Sodium hydroxide also may be used; but it has the disadvantages of greater chemical action on the glass, and it forms a bicarbonate precipitate more readily than potassium hydroxide. The fuming sulphuric acid when fresh should contain 20% to 25% free sulphur trioxide. Bromine water (prepared by dissolving bromine in water until an excess of liquid bromine remains in the bottom of the pipette) also may be used to absorb illuminants, but should not be used when mercury is used as the confining liquid. Alkaline pyrogallate is prepared by dissolving 50 g. of pure pyrogallic acid in 150 ml. of distilled water, and mixing with a solution containing 1,200 g. of potassium hydroxide in 800 ml. of water. The mixture should be immediately protected from the air. Oxygen may be absorbed by other reagents such as white phosphorus, chromous chloride or acetate, and sodium hydrosulphite. There are objections to the use of these reagents and therefore alkaline pyrogallate is usually employed. For the absorption of carbon monoxide, acid cuprous chloride (450 g. of chemically pure cuprous chloride dissolved in 2,500 ml. of concentrated C.P. hydrochloric acid) is frequently used, but cuprous sulphate beta-naphthol is being used more than in the past. The latter is prepared from cuprous oxide, 20 parts; sulphuric acid, 200 parts; water, 25 parts; and beta-naphthol, 25 parts.

Analytical Procedure.—Before starting an analysis, the apparatus should be checked to be sure that it is in proper operating condition. It should be tested for leaks to assure that the sample is not lost or diluted with air. A small amount of water

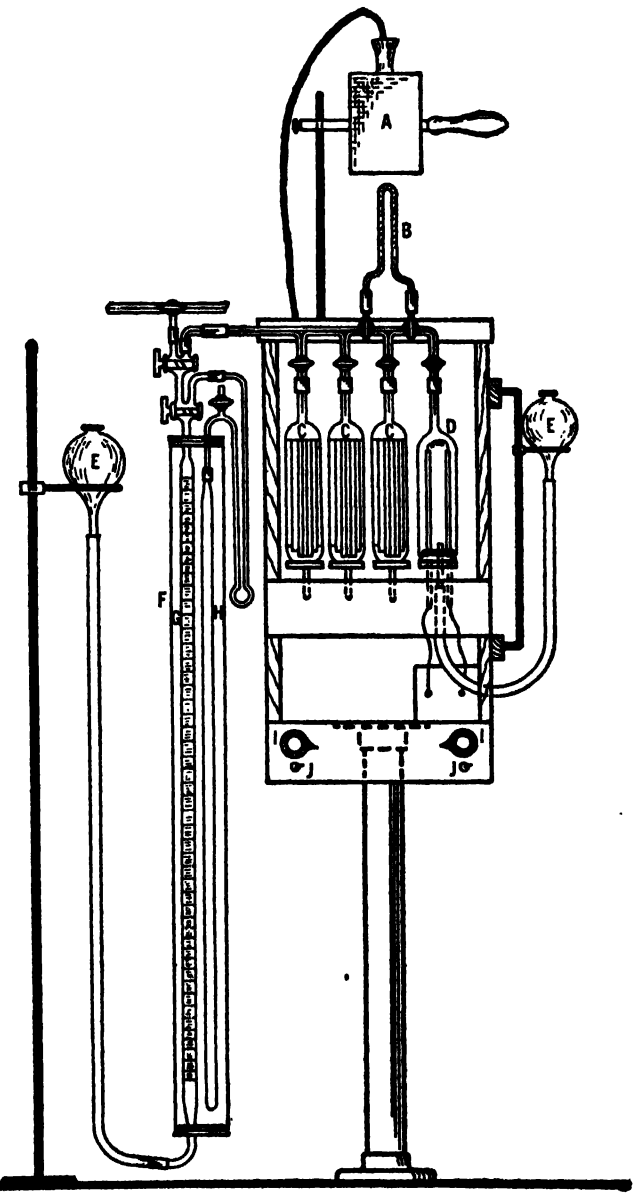

FIG. 6.—ORSAT-TYPE GAS-ANALYSIS APPARATUS. A. ELECTRIC FURNACE FOR COPPER OXIDE TUBE; B. COPPER OXIDE TUBE; C. ABSORPTION PIPETTES; D. COMBUSTION PIPETTE; E. LEVELLING BULBS; F. WATER JACKET; G. BURETTE; H. COMPENSATING TUBE; I. RHEOSTATS; J. SWITCHES

should be placed in the burette and in the compensator tube. The air in the compensator tube should be adjusted to atmospheric pressure. The capillary tubes of the manifold through which the sample is passed to the pipettes and copper oxide tube should be swept free of air by drawing a sample of air into the burette, absorbing the oxygen in the alkaline pyrogallate solution, and then passing the residual inert gas through the apparatus.

To obtain a sample for analysis, the mercury reservoir or levelling bulb is raised to free the burette of air. The burette is then connected to the gas sample container with capillary tubing and the levelling bulb lowered to draw the sample into the burette. The stopcock at the top of the burette is closed and the volume of gas in the burette is read at atmospheric pressure by adjusting the mercury in the levelling bulb and burette to the same level. The analyst is now ready to proceed with the analysis.

Carbon Dioxide.—The stopcocks are aligned so that the sample can be forced, by raising the levelling bulb, from the burette into the pipette containing the potassium hydroxide. The levelling bulb is alternately lowered and raised in order to pass the sample back and forth from the burette to the pipette. This procedure facilitates absorption of the carbon dioxide which should be completely removed after four or five passes into the pipette. The levelling bulb is finally lowered until the potassium hydroxide reaches a mark on the capillary at the top of the pipette. The stopcock to the pipette is then closed and the volume of gas in the burette read as previously described. The decrease in volume is due to removal of carbon dioxide as the other constituents are not absorbed. If the original volume of the sample was 100 ml., and after removal of carbon dioxide 98 ml., then the amount of carbon dioxide present in the sample was 2 ml. or 2 parts in 100, that is, 2% by volume.

Illuminants.—The stopcocks are now aligned so that the sample can be passed into the pipette containing the fuming sulphuric acid. The sample is passed into the pipette three or four times as described for carbon dioxide. However, before reading the volume, the sample is passed once or twice into the potassium hydroxide pipette to remove any sulphur trioxide vapours removed from the fuming sulphuric acid. The volume of the residual gas is then read on the burette. If the reading is 95 ml., then 3 ml. (98 minus 95) or 3% illuminants are present.

Oxygen.—The procedure described for carbon dioxide and illuminants is repeated, passing the sample into the pipette containing the alkaline pyrogallate 6 to 12 times depending on the concentration of oxygen in the sample. If the burette reading has decreased from 95 to 94 ml., then the sample contains 1 ml. or 1% oxygen.

Carbon Monoxide.—The procedure used for the previous constituents can be used for determining carbon monoxide by passing the sample five or six times into a pipette (not shown in fig. 6) containing one of the absorbents for carbon monoxide. The percentage present is calculated in the same way as carbon dioxide.

Carbon monoxide also may be determined by oxidation with copper oxide as described below.

Hydrogen and Carbon Monoxide.—The stopcocks are aligned so that the residual sample can be passed through the copper oxide tube which is heated by means of a small furnace to from 290° to 310° C. The sample is passed through the copper oxide tube slowly (about 10 ml. per minute) and returned to the burette. This operation is repeated and the contraction in volume noted. The carbon dioxide produced by the oxidation of carbon monoxide is then determined as described previously for carbon dioxide. The reactions which take place are as follows:

$$H_2 + CuO = H_2O + Cu$$
$$CO + CuO = CO_2 + Cu$$

Thus for hydrogen there is a decrease in volume equal to the amount of hydrogen in the sample since the water formed condenses and occupies a negligible space. The carbon monoxide produces an equal volume of carbon dioxide and therefore no change in volume. The volume of hydrogen in the sample equals the contraction of the sample after oxidation and the volume of carbon monoxide is equal to the volume of carbon dioxide produced.

Methane and Ethane.—At this stage in the analysis the residual gas may consist of methane, ethane and inert gases, mainly nitrogen. Since methane and ethane require oxygen for combustion, it is necessary to add oxygen. The residual gas is stored in the potassium hydroxide pipette and an excess of oxygen necessary for combustion of the methane and ethane is carefully measured in the burette. The oxygen is passed into the combustion pipette and the residual gas returned to the burette. The platinum spiral at the top of the combustion pipette is heated electrically to a bright yellow and the residual gas passed slowly (about 10 ml. per minute) into the combustion pipette. Methane and ethane are oxidized to carbon dioxide according to the following equations:

$$CH_4 + 2O_2 = CO_2 + 2H_2O$$
$$2C_2H_6 + 7O_2 = 4CO_2 + 6H_2O$$

On the basis of these reactions, the percentages of methane and ethane can be calculated as follows:

$$\text{Per cent of ethane} = \frac{(2 \times \text{carbon dioxide} - \text{contraction}) \times 100}{1.5 \times \text{ml. sample taken}}$$

$$\text{Per cent of methane} \quad \frac{(\text{carbon dioxide} - 2 \times \text{ethane}) \times 100}{\text{ml. sample taken}}$$

The sum of the percentages of all the constituents determined is then subtracted from 100 and the remainder is the percentage of nitrogen or inert gas in the sample.

In presenting the analytical procedure, only the basic steps have been described and no attempt has been made to incorporate numerous minor steps that are necessary to obtain accurate results.

To do so would require lengthy details which would add little and at the same time make it difficult to follow the general outline of the procedure.

Typical Values for Individual Constituents of Several Kinds of Fuel Gas

Kind of gas	Carbon dioxide	Illuminants	Oxygen	Carbon monoxide	Hydrogen	Methane	Ethane	Nitrogen
Natural	..	..	..	..	..	85.5	13.5	1.0
Blast furnace	10.8	..	..	28.2	0.8	..	..	60.2
Producer	5.6	..	0.4	25.4	15.2	1.4	..	53.0
Coal	2.1	3.3	0.4	8.2	50.5	28.6	..	6.9
Blue (water)	5.2	..	0.6	41.5	48.7	1.4	..	3.6
Carburetted water	2.7	0.2	0.7	33.6	35.2	12.4	..	6.2
Coke oven	1.9	3.5	0.3	6.4	52.5	30.6	..	4.8

Information on the composition of a fuel gas can be used in various ways, for example, calculation of heating value and specific gravity of the gas, data which are essential for the safe and efficient utilization of gaseous fuels.

Haldane Apparatus.—Another gas volumetric apparatus widely used for the analysis of mine atmospheres and samples that contain small quantities of carbon dioxide, combustible gases and oxygen, with an accuracy greater than that obtainable with the apparatus of the type previously described, is known as the Haldane apparatus. The basic principles of the apparatus and procedures are the same as for those of other gas volumetric methods of analysis. The conventional apparatus consists of a water-jacketed burette and compensator, two absorption and one combustion pipettes. The burette consists of an ungraduated bulb at the top having a volume of 15 ml. and a stem with a volume of 6 ml. graduated to 0.01 ml. Samples to be analyzed must not contain an explosive mixture of combustible gases, and there must be sufficient oxygen in the sample to burn completely all the combustible gases. Carbon dioxide is removed first, then the combustibles (methane, hydrogen and carbon monoxide), and finally oxygen. The oxygen determined is that remaining after combustion, and therefore it is necessary to add the amount consumed by the combustion.

Calculation of results is essentially the same as for the Orsat type of apparatus.

Bone-Wheeler Gas Analysis Apparatus.—The Bone-Wheeler gas-analysis apparatus is used to a considerable extent in England. Its use in the United States is very limited. This apparatus is based on the principle of measuring change in pressure at constant volume. Instead of removing the gases in a series of

pipettes they are removed in a single absorption vessel. The reagent for a single constituent is added to the vessel and the gas removed, and the change in pressure at constant volume measured. The reagent for that gas is then removed from the absorption vessel and the reagent for the next gas added to the absorption vessel. In other words, instead of using a pipette in which a constituent can be removed from a number of samples, a small amount of new reagent is used for each constituent and is then discarded.

Although it has the advantage of requiring a small sample and is independent of the atmospheric pressure, disadvantages in operative procedures have prevented its wide application.

Sampling.—It is not within the scope of this article to discuss in any detail the various methods of collecting gas samples. However, regardless of refinements and care in analytical procedures no analysis can be more accurate than the sample. Therefore, it is of the utmost importance that the sample be properly taken and handled so that there is no possibility of contamination.

Jones (1926); American Gas Association, *Gas Chemists' Handbook*, 3rd ed. (1929); V. J. Altieri, *Gas Analysis and Testing of Gaseous Materials* (1945). (H. H. SE.)

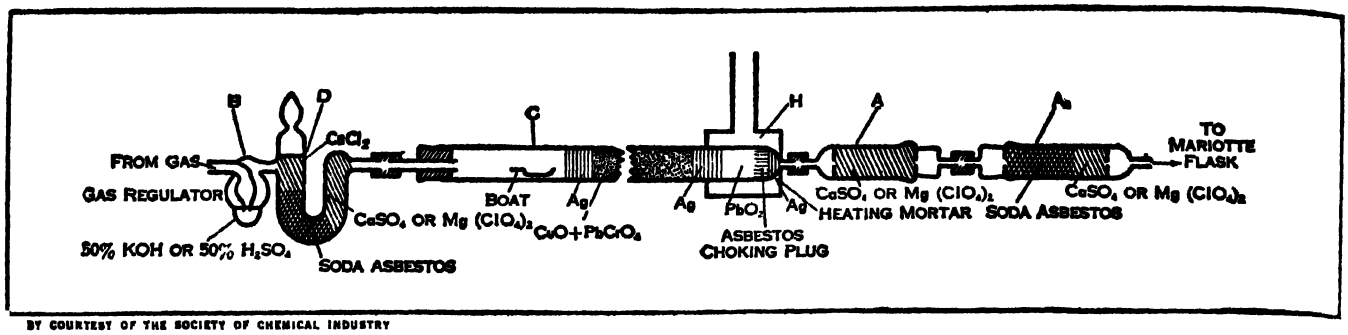
MICROANALYSIS

Chemical analysis becomes chemical microanalysis when the quantities of substance handled, examined, or measured are significantly (ten or more times) smaller than customary. Depending upon the reduction factor, one speaks of semimicro, micro or ultramicro procedures or methods. Since these terms convey no definite meaning, it appears preferable to follow Friedrich Emich's suggestion and to speak of a centigram, milligram, microgram, etc., scale so as to indicate the amount of material under investigation.

The emergence of microchemistry and microanalysis as a separate discipline was the result of the teachings of Emich who, about 1893, started a systematical development of micromethods of chemistry by embarking on a study of all kinds of chemical experimentation on an ever increasingly small scale. It may be said that the chemistry with which we are familiar is essentially independent of the scale of experimentation as long as approximately 1,000,000 molecules or approximately 10^{-16} g. = 0.0000001 mγ (milligammas), (1 gram = 1000 mg.; 1 mg. = 1000 γ; 1γ = 1000 mγ) of material are taking part in the reaction. Consequently, only the technique of handling, observation, and measurement must be changed with the scale of working. Emich developed micromethods of chemistry not only for the purpose of qualitative and quantitative analysis, but also for preparatory work, physicochemical studies and lecture demonstration.

Since most of our information regarding matter is derived from visual impressions, the microscope must be employed whenever the amounts of material become so small that the unaided eye can no longer be relied upon to report satisfactorily appearances and direct tools. The microchemical balance, originally designed by W. H. Kuhlmann in Hamburg, was drafted for service in microanalysis mainly because of its large carrying capacity of 20 g., which is required for the weighing of the absorption tubes of organic combustion analysis. A variety of microbalances with beams of vitreous silica and using different principles for weighing (elasticity and torsion forces, buoyant effect, electromagnetic attraction were designed by E. Salvioni, W. Nernst, B. D. Steele and K. Grant, R. W. Gray and Sir W. Ramsay, H. Pettersson, F. W. Aston, F. Emich and later by O. H. Lowry, H. V. Neher, P. L. Kirk with R. Craig, J. E. Gullberg and R. Q. Boyer, H. M. Barrett, A. W. Birnie and M. Cohen, C. H. Wilson and H. M. El-Badry, and F. C. Edwards and R. R. Baldwin for studies on very small quantities of material. Microscope and microbalances occupy a prominent position in microanalysis, but their role as necessary tools is incidental.

Determination of the rate of radioactive decay, spectroscopy, spectrophotometry, colorimetry, fluorimetry, nephelometry, polarography, chromatography and microbiological assay methods possess in certain instances high specificity and extraordinary sensitivity so as to give them a supreme position for the determination of trace constituents. Application of these methods on a small scale gives a further increase of their efficiency, and truly amazing limits may be obtained. Spectrophotometric measurements as performed by Paul L. Kirk with the use of a cell two millimetres in diameter and five centimetres long attain a sensitivity of 0.1 mγ. A. E. Mirsky and A. W. Pollister have performed colorimetric measurements in the microscopic image of tissue thin sections, and they were able to measure as little as 0.0001 mγ of tyrosine. Small-scale performance of microbiological assay allows accurate estimations of quantity with less than one milligamma of certain substances.



Also simple analytical test tube tests may be given sensitivities from 0.0001 to 0.00001 mγ or 10^{-13} to 10^{-14} g. by performing them with the use of micromanipulators under the high-power microscope. In general, one may state that the development of chemical microtechnique is now sufficiently advanced to permit, at least theoretically, performance of any analytical task on as small a scale as becomes necessary or seems desirable on the basis of practical considerations.

Microchemical methods are continuously gaining importance since all branches of research are by necessity turning to the study of increasingly smaller detail in their quest for final answers. The effects of trace constituents have become of ever-growing interest in the study of living matter as well as in the perfection of industrial processes and products and in the maintenance of all kinds of structures and equipment. In spite of the availability of especially suitable methods for the determination of traces, the co-operation of the microanalyst becomes increasingly desirable. In physiological and pathological studies on small animals as well as in the chemical laboratories of pediatric institutes, all chemical work must be performed on a small scale, since large samples of body liquids cannot be taken without upsetting the existing conditions. Finally, the chemical investigation of dangerous materials such as explosives or highly radioactive materials becomes less hazardous when done on a sufficiently small scale.

Qualitative Microanalysis.—Modern teaching of inorganic qualitative analysis is done on a semimicro or centigram scale with the use of spot tests for confirmatory tests. In at least one instance the milligram scale has been adopted, and the confirmatory tests are observed under the microscope. Schemes of analysis including rare elements have been tried on the centigram as well as on the milligram scale. A technique for efficient work on the microgram scale, with sensitivities from one to ten milligammas for the confirmatory tests, was developed during the late 1930s. Most operations are performed under the low-power microscope with the aid of simple manipulators having rack-and-pinion motions. The technique may be readily acquired, and the work may be conveniently observed by large audiences, if microprojection is used. The microgram technique is, of course, applicable to general chemical experimentation, and it seems to have been used in the study of the chemistry of small quantities of elements produced by the cyclotron or obtained as a consequence of atomic fission. Since most of the work is done by remote control, the technique is especially attractive for work with highly radioactive matter.

Since each element produces its own characteristic spectrum, an examination, by means of the spectroscope, of the flame or spark spectrum of a substance reveals the identities of the elements present. The delicacy of the method transcends that of the most sensitive chemical reactions. The presence of one-hundred-thousandth part of a milligram of lithium may be revealed by means of the spectroscope; or, again, five hundred-thousandths of a milligram of the rare gas, neon, present in the atmosphere, may be detected. In this manner the metallic elements gallium, rubidium, indium, caesium and thallium were discovered. The absorption spectra of many inorganic and organic substances are also characteristic, thus enabling the presence of these substances to be recognized. Examples are: copper sulphate; the blood pigments (haemoglobin and oxyhaemoglobin); and the porphyrins. (*See* SPECTROSCOPY.)

Far more widely employed, however, are the purely chemical

methods which depend upon the production, on the addition of reagents to the sample or to its solution, of colorations or of colour changes; of precipitates having characteristic odour, colour or crystalline form; or of gases or liquids which can be distilled over and identified. These tests, many of which are very delicate, may be specific for particular compounds, radicals or elements; or for groups of these. Thus, the presence of 1 part of copper in 100,000,000 parts of water is shown by the blue colour produced on the successive addition of alcoholic hydrogen peroxide and guaiacum resin in pyridine. The presence of 1 part of gold in 20,000,000 parts of solution is revealed by the yellow coloration given with *o*-tolidine. Prussic acid (1 part in 2,000,000 of air) may be detected by means of the blue colour which it gives upon a test paper moistened with a solution containing *o*-tolidine, acetic acid and copper acetate. There are many hundreds of such tests, some of which are also quantitative.

Schemes of organic qualitative analysis may be carried out on a centigram or milligram scale by means of microtechniques developed mostly by Emich and his co-workers. The observation of *schlieren* for a criterion of purity was introduced by Emich and may find increasing application. Ludwig and Adelheid Kofler in Innsbruck, Austria, originated a system for the identification of organic compounds in simple mixtures, which is based on the determination of melting points under the microscope. Their technique also furnishes information on polymorphism and isomorphism, and it allows a quick survey of the melting point diagrams of mixtures.

Quantitative Microanalysis.—Complicated separations involving rare elements and followed by the determination of the isolated constituents have been carried out on the milligram scale. The most flexible technique of filtration is provided for such work by the use of Emich's filterstick, an immersion filter consisting essentially of a tube with a filter mat near its lower (immersed) opening. Any desirable material may be used for tube as well as for the filter mat. The foundation for gravimetric work on a microgram scale has been laid by Emich's systematic investigations on highly sensitive microbalances with beams of vitreous silica. Little progress has been made beyond the performance of simple residue determinations and electrolytic precipitations.

A systematic investigation of titrimetry, predominantly on the milligram scale, has been carried out by J. Mika. Titrimetric and colorimetric methods are, however, widely used on the microgram scale. A variety of burets have been developed for the purpose; some use the principle of the injection syringe, and others rely on the surface tension force originating in the fine tip to take the place of the stopcock of the customary buret. With the latter type it is possible to dispense and measure volumes of standard solutions down to 0.0002 cu.mm. by adopting the injection technique of the microbiologist and performing the titration in the field of a microscope.

Micromethods for the determination of density, some based on the use of pycnometers and some based on the principles of the floating and falling drop methods, have been applied to the determination of heavy water and to various biochemical studies. Of the gasvolumetric and manometric procedures, the very sensitive technique of D. D. van Slyke has demonstrated its great versatility. An ingenious adaptation of the principle of the Cartesian diver for gasvolumetric determinations on a microgram scale has been made by K. Linderstrom-Lang.

The milligram and centigram procedures of organic elementary analysis (determination of carbon, hydrogen, nitrogen, oxygen, sulphur, halide, phosphorus, arsenic, metallic constituents) have almost displaced the old macromethods, and the same may be said of the micromethods for the determination of the active groups in the molecule. Economy with regard to the material under investigation has become progressively more important as organic chemistry turned to the study of biochemical problems. The superiority of the micromethods in reliability and general efficiency is no longer questioned. The original methods of F. Pregl are still widely used with and without modifications. Micro adaptations of the tube filling of M. Dennstedt have been recommended by A. Friedrich and S. Ingram. In general, there is a tendency toward mechanizing the work with the use of automatic furnaces.

A brief outline of one of the most important processes is given below:

Determination of Carbon and Hydrogen.—A weighed quantity (three to five milligrams) of the substance, placed in a small platinum boat, is burned in a current of oxygen (dried by passage through the tubes B and D) in the apparatus shown in figure 7. The hard-glass tube, C, is 40 cm. in length, and contains a filling of chemicals (as indicated in the diagram) designed to arrest the escape of nitrogen, sulphur, halogens and other products which might vitiate the analysis. The remaining gaseous products of the combustion, water and carbon dioxide, are swept over with air, and are retained, respectively, in the tubes A_1 and A_2, which are weighed on the microbalance both before and after the experiment. From the gains in weight of these tubes, the amounts of hydrogen and carbon in the original material are calculated. The gas pressures at different points of the apparatus are carefully regulated, and the temperature of the lead peroxide is maintained at 180° C. by means of the external heating device shown at H. Practically all classes of organic substances may be analyzed with great accuracy in this apparatus.

Micromethods for the analysis of small samples of gases, originally introduced by C. Timiriazeff and A. Krogh, have been variously modified and refined for use in connection with chemical, industrial, biological, and medical work.

CHEMISTRY, APPLIED: *see* CHEMICAL ENGINEERING.

CHEMNITZ, or KEMNITZ, **MARTIN** (1522–1586), German Lutheran theologian, born at Treuenbrietzen, Brandenburg, on Nov. 9, 1522. He went (1543) to the University of Frankfurt-on-Oder and then (1545) to the University of Wittenberg, where he heard Martin Luther preach but was more attracted by Philipp Melanchthon, who interested him in mathematics and astrology. He practised astrology, and this recommended him to Albert Frederick, duke of Prussia, who made him his librarian (1550). Returning in 1553 to Wittenberg, he lectured on Melanchthon's *Loci Communes,* his lectures forming the basis of his own *Loci Theologici* (published posthumously, 1591), an exposition of Lutheran theology. He moved to Brunswick on Dec. 15, 1554, to become coadjutor to the superintendent, Joachim Mörlin.

Against the Crypto-Calvinists he upheld the Lutheran view of the Eucharist in his *Repetitio sanae doctrinae de Vera Praesentia* (1560; in German, 1561). Other works include *Theologiae Jesuitarum praecipua capita* (1562), an attack on the society's principles; *Examen concilii Tridentini* (four parts, 1567–73); and *Corpus doctrinae Prutenicum* (1567), drawn up in conjunction with Mörlin. He resigned from his office as superintendent of Brunswick in 1584, and he died on April 8, 1586.

CHEMNITZ, a town of Germany, in the *Land* of Saxony, the capital of a governmental district, 50 mi. W.S.W. of Dresden and 51 mi. S.S.E. of Leipzig. Pop. (1939) 334,563.

Chemnitz (*Kaminizi*) was originally a settlement of the Sorbian Wends and became a market town in 1143. Its municipal constitution dates from the 14th century, and it soon became the most important industrial centre in the mark of Meissen. A monopoly of bleaching was granted to the town, and thus a considerable trade in woollen and linen yarns was attracted; paper was made here, and in the 16th century the manufacture of cloth was very flourishing. In 1546 the Benedictine monastery, founded about 1136 about 2 mi. north of the town, was dissolved. During the Thirty Years' War, Chemnitz was plundered by all parties and its trade was completely ruined, but at the beginning of the 18th century it had begun to recover. Further progress was made during the 19th century, especially after 1834 when Saxony joined the German *Zollverein.*

The town lies 950 ft. above sea, in a fertile plain at the foot of the Erzgebirge, watered by the river Chemnitz, an affluent of the Mulde. It is the chief manufacturing centre in the kingdom and ranks next to Dresden and Leipzig in point of population. It is well provided with railway communication, being directly connected with Berlin and with the towns of the Erzgebirge and Vogtland. The centre of the town is occupied by the market square, with the mediaeval *Rathaus,* now superseded by a modern building in the Post-strasse. The old inner town is within the old fortifications, and beyond lies industrial Chemnitz. There is an ancient Gothic church dedicated to St. James. To the northwest of the town is the Gothic church of a former Benedictine monastery, dating from 1514–1525, with a tower of 1897. The industry of Chemnitz has gained for the town the name of "Saxon Manchester." First in importance are its locomotive and engineering works. Next come its cotton-spinning, hosiery, textile and glove manufactures. It also has considerable dyeworks, bleachworks, chemical and woollen factories. The local communications are maintained by an electric tramway system.

Chemnitz is a favourite tourist centre for excursions into the Erzgebirge.

CHEMUNG CANAL, a canal and lock system completed in 1833, which connected the Susquehanna river with Seneca lake. It was 23 mi. long and had 49 locks, which were built of wood.

It was built during the era after 1826 when many states started ambitious inland water development projects.

CHEMURGY is not so new as its name. The latter was invented in 1935 and is said to be derived from two Greek words, the combination of which may be freely translated as "chemistry at work." Chemurgy, used in conjunction with the word "farm," gives us "farm chemurgic," which has been defined as "chemistry at work on the farm."

The farm chemurgic movement rose in the United States because of the distress caused by the enormous crop surpluses blocking the farmers' market in the late 1920s and middle 1930s. It was started in 1935 by a group of industrialists, agriculturists, and economists, who proposed to meet this problem in three ways: (1) By the discovery of new uses for established farm crops; (2) by the development of new crops to replace acreage already devoted to surplus crops; and (3) through the utilization of farm wastes, better described as "farm residues."

In a broad general sense, under the present marketing system, nearly all agricultural crops enter into industry, but these normal industrial applications are based on the old agricultural standards, food, raiment and shelter. These uses have not been changed essentially since the middle of the 19th century and have only been made more complex by the coming of the industrial age and the departure of most agricultural industry from the farm. The substitution of the power loom for farm weaving and the replacement by the tin can of the home container do not mean that more wool, cotton, or farm produce are consumed than previously, but merely that they are used elsewhere and travel farther than they did in the days when wool moved almost directly from the back of the sheep to the back of its owner. The controlling factors are financial rather than physical.

Many factors contributed to the building up of the burdensome crop surpluses of the 1920s and 1930s. The advent of automotive vehicles and the departure of the horse left available for farm products of other kinds the 30,000,000 ac. in the United States formerly devoted to forage crops, while the markets for these products remained stationary or nearly so. The introduction of the tractor greatly increased the productiveness of the farmer, while the development of high-yielding crop varieties and the extensive use of fertilizers led to a greater yield of crops per acre. Thus the farmers' productivity increased while the traditional uses for his products were either stationary or diminishing.

With the beginning of the 20th century, the so-called industrial utilization of all agricultural raw materials for purposes other than those of foods and feeds began to receive the attention of many organizations in the United States, notably that of the U.S. department of agriculture. Much work was done on the manufacture of alcohol from starchy crops; on the introduction of new crops for fibres, alcohol, and oil; and on the production of paper and furfural from corn stalks, wheat straw, corncobs, and other agricultural residues. Most of these investigations were completed on a laboratory and a pilot-plant scale and then abandoned because of unfavourable economic values. Matters stood at this point when the farm chemurgic movement was started. Those interested in improving the situation of the farmer—businessmen, agriculturists and scientists—got together to form a committee. This committee mailed out invitations for a conference of agriculture, industry, and science. The first meeting was held at Dearborn, Mich., in 1935. It resulted in the formation of the National Farm Chemurgic council, the central organization of the chemurgic movement in the United States. Its chief function by 1947 was to further and supervise the activities of local and regional groups interested in the advancement of chemurgic objectives. These groups sponsor local and regional conferences at which the chemurgic possibilities of the area are discussed by representatives of agriculture, science and business. The discussions cover a great variety of fields, all the way from working industrial developments and new research achievements to highly speculative suggestions for new crops. The result has been a distinct advance in state, industrial and government accomplishments in chemurgy. In fact, it may well be said that the chemurgic movement is responsible for the biggest government venture in this field—the establishment of the four regional research laboratories of the U.S. department of agriculture.

The background of the establishment of these laboratories is of

interest.

The Bankhead-Jones bill, providing funds for additional research in the department of agriculture and the state agricultural experiment stations, became effective on July 1, 1935. The U.S. Regional Soybean Industrial Products laboratory was set up under the provisions of this bill on July 1, 1936. This was a real chemurgic laboratory, devoted primarily to finding new nonfood industrial uses for the soybean. Its success in the fields of paints and varnishes from soybeans, and plastics and fibres from soybean protein, led to the introduction in congress of a flood of other bills proposing the establishment of similar laboratories to do for other crops what soybean laboratory was doing for the soybean.

This agitation culminated in an amendment to the Agricultural Adjustment act of 1938. This amendment led to the establishment of the four regional research laboratories, whose chief functions were to be the study of new uses for agricultural raw materials. These laboratories, sometimes known as the "chemurgic laboratories," were established with a great deal of care. The sites were chosen with a view to such facilities as water, sewage disposal, transportation and easy access to possible industrial co-operators. The buildings were designed according to the latest construction developments, including ample provisions for work on a semi-industrial scale. They cost, fully equipped, around $2,000,000 each. Accommodations were planned for approximately 200 scientists and 100 auxiliary workers. The laboratories were located at Peoria, Ill.; New Orleans, La.; Philadelphia, Pa.; and Albany, Calif.; and were appropriately named for the four points of the compass.

The commodities to be studied were selected by a department of agriculture committee and were chosen primarily from among those agricultural products then in surplus. They were as follows: Northern laboratory: cereal crops, oilseeds of the area, agricultural residues; Southern laboratory: cotton, peanuts, sweet potatoes; Eastern laboratory: dairy products, tobacco, apples, white potatoes, vegetables, animal fats and oils, hides, skins and tanning materials; Western laboratory: fruits, vegetables, alfalfa, wheat, poultry products. In those cases where duplication of effort, resulting from the assignment of similar commodities to two laboratories, was thought possible, special care was taken in the arangement of the research program.

In due course, the laboratories were constructed and staffed, and work was begun on the commodities assigned to them. A number of important discoveries have been made and the use of agricultural commodities and their by-products has been greatly extended. For instance, the work of the Northern Regional Research laboratory on penicillin led to the additional use of 8,000,000 lb. of milk sugar and 12,000,000 lb. of corn steep liquor annually. The Eastern Regional Research laboratory has produced rutin from buckwheat, an accomplishment which was expected to lead to the planting of more than 50,000 ac. annually in buckwheat. (Rutin is a yellow substance, chemically a glucoside. In powder form it has proved beneficial in clinical tests for reducing the fragility of capillary blood vessels that accompanies some types of high blood pressure.)

The emphasis laid on government research in the preceding paragraphs should not be allowed to obscure other chemurgic investigations. Some of the agricultural experiment stations in the U.S. were engaged in such studies and there were many industrial organizations working on uses of agricultural commodities in fields quite apart from food, raiment and shelter. An outstanding illustration is found in the announcement of one large commercial organization that it had worked out processes by which 2,000,000 lb. of corncobs would be used annually as the basis for the manufacture of nylon. However, the basic elements of the process for the manufacture of furfural, an important step in this industrial sequence, were discovered in the department of agriculture in 1920. All of which demonstrates that chemurgy is an established influence in agricultural research.

As chemurgy develops further, it can and will have an outstanding influence on national economy in the U.S. No nation can live indefinitely on its capital and avoid bankruptcy. Agricultural commodities are reproducible and represent income rather than capital.

A nation which uses them largely in industry is simultaneously conserving its other resources. This is only one of the lessons of chemurgy. (H. T. H.)

See Wheeler McMillen, *New Riches from the Soil* (1946).

CHENAB, one of the "Five rivers" of the Punjab, Pakistan (the Greek Acesines). It rises in the snowy Himalayan ranges of Kashmir, enters Pakistani territory in the Sialkot district, and flows through the plains of the Punjab, forming the boundary between the Rechna and the Jech Doabs. Finally it joins the Jhelum at Trimmu.

The Chenab colony, resulting from the success of the Lower Chenab canal in irrigating the desert of the Bar, was formed out of the three adjacent districts of Gujranwala, Jhang and Montgomery in 1892. It lies in the Rechna Doab between the Chenab and Ravi rivers in the northeast of the Jhang district, and includes an irrigated area of more than 2,500,000 ac. The principal town is Lyallpur (pop. 1941, 69,930) called after Sir J. Broadwood Lyall, lieutenant governor of the Punjab. It is now an important trade centre, and gives its name to a district with an area of 3,224 sq.mi. and a population (1941) of 1,396,305. The Lower Chenab canal is now supplied with water from the Jhelum through the Upper Jhelum Canal, and the Chenab water is utilized for the upper Chenab canal.

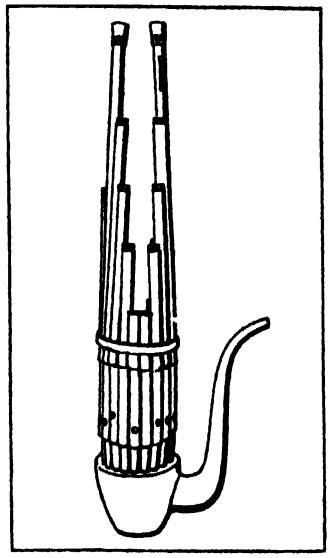
This canal, opened in 1912, which has 173 mi. of main canals and distributaries, and irrigates more than 500,000 ac., forms part of the great Triple canals project.

CHÊNEDOLLÉ, CHARLES JULIEN LIOULT DE (1769–1833), French poet, was born at Vire (Calvados) on Nov. 4, 1769. He early showed a vocation for poetry, but the outbreak of the Revolution temporarily diverted his energy. Emigrating in 1791, he fought two campaigns in the army of Condé, and eventually found his way to Hamburg, where he met Antoine de Rivarol, of whose brilliant conversation he left an account. He also visited Mme. de Staël in her retreat at Coppet.

On his return to Paris in 1799, he met François Chateaubriand and his sister Lucille (Mme. de Caud), to whom he became deeply attached. After her death in 1804, Chênedollé returned to Normandy, where he married and became eventually inspector of the academy of Caen (1812–32). With the exception of occasional visits to Paris, he spent the rest of his life in his native province. He died at the château de Coisel on Dec. 2, 1833.

He published his *Génie de l'homme* in 1807, and in 1820 his *Études poétiques,* which had the misfortune to appear shortly after the *Méditations* of Alphonse Lamartine, so that the author did not receive the credit of their real originality.

Chênedollé had many sympathies with the romanticists, and was a contributor to their organ, the *Muse française.* His other works include the *Esprit de Rivarol* (1808) in conjunction with F. J. M. Fayolle.



The works of Chênedollé were edited in 1864 by Charles A. Sainte-Beuve, who drew portraits of him in his *Chateaubriand et son groupe* and in an article contributed to the *Revue des deux mondes* (June 1849).

BIBLIOGRAPHY.—E. Helland, *Étude biographique et litteraire sur Chênedollé* (1857); Cazin, *Notice sur Chênedollé* (1869); and L. de Samie, *Chênedollé* (1922).

CHENERY, THOMAS (1826–1884), English scholar and editor of the *Times,* was born at Barbados and educated at Eton and Caius college, Cambridge. Having been called to the bar, he went out to Constantinople as the *Times* correspondent just before the Crimean War, and it was under the influence there of Algernon Smythe (afterward Lord Strangford) that he first turned to those philological studies by which he became eminent. After the war he returned to London and wrote regularly for the *Times* for many years, eventually succeeding Delane as editor in 1877. He was then an experienced publicist, particularly well versed in oriental affairs, an indefatigable worker, with a rapid and comprehensive judgment, though he lacked Delane's intuition for public opinion. In 1868 he was appointed Lord Almoner's professor of Arabic at Oxford, and retained his position until

became editor of *The Times*. He was one of the company of revisers of the Old Testament. He was secretary for some time to the Royal Asiatic Society, and edited the Arabic classic *The Assemblies of Al-Hariri* and the *Machberoth Ithiel*. He died in London on Feb. 11, 1884.

CHENG, TSCHENG or TSCHIANG (Ger. *Scheng*), an ancient Chinese wind instrument in the nature of a primitive portable organ, containing the principle of the free reed which found application in Europe in the accordion, concertina, and harmonium. In shape the cheng resembles a closed teapot to the top of which are fitted bamboo pipes of graduated lengths and furnished in the side with an insufflation tube curved like a swan's neck or the spout of a teapot.

OF ART

CHÊNGTU, the administrative centre of the province of Szechwan and the regional capital of West China, situated 30° 40′ N., 104° 12′ E. In the north-west corner of the Red Basin of Szechwan there lies a smooth plain some 70 miles by 40, whose even surface contrasts strongly with the rest of the highly dissected Basin. Chêngtu is the centre of this plain which forms the deltaic fan of the Min-Ho below its debouchure at Kwan-hien from the high mountain country of north-west Szechwan. By means of a marvellous irrigation system, initially planned by Li Ping in the 3rd century B.C. and further elaborated at several subsequent periods, the river waters are now led off at Kwan-hien along innumerable irrigation channels to fertilize the whole plain instead of littering it with gravel as in its natural state. At the lower end of the plain the channels are drawn together and issue as two rivers, the Min-Ho, and the Chung-kiang, which join the Yangtze at Suifu and Luchow respectively. Although on the average 2,000 ft. above sea-level, the Chêngtu plain lies in a very sheltered position and yields exceptionally heavy crops of all the varied products typical of Middle China (*see* CHINA).

Chêngtu also serves as the commercial outlet of the mountain country of north-west Szechwan, the pastoral products of which are utilized in the industries of the city. Because of its position at the contact of plain and mountain Chêngtu focuses the life of the sheltered agricultural Red Basin and the rugged pastoral mountain country of the west Szechwan border. The Red Basin of Szechwan lies in the far west of China and Chêngtu is placed on the western border of the Red Basin. After 1937, prominent Chinese universities moved to Chêngtu, including the University of Nanking, Yenching university, Ginling College for Women. Szechwan university and the West China Union university are also here. Manufacturing plants were established in Chêngtu for improved agricultural equipment. In the fall of 1940 the First National Forestry and Soil Conservation conference was held there. The population of Chêngtu was 440,988 (1934).

CHÉNIER, ANDRÉ DE (1762–1794), French poet, was born at Constantinople of a French father and a Greek mother. parents returned to France in 1765, and though the father afterwards served as consul general in Morocco, the children (Marie-Joseph is noticed below) remained in France. André was educated at the college de Navarre in Paris, and after some months in the army at Strasbourg, returned to Paris, where he met the poets and artists of the day in his mother's salon. A visit to Italy in 1784 made a deep impression on his mind, and strengthened his passion for the antique. The next three years were spent in experimenting in eclogues and idylls in the classical manner. Of the works of this period the most famous is *La jeune Tarentine*, classical in form, but characterized by the grace and charm which informed all Chénier's work. He proposed to write and actually composed fragments of a poem modelled on Lucretius, *Hermès*, which was to cover the contents of the *Encyclopédie*. In 1787 he went to London as secretary to his relative, M. de la Luzerne, at that time French ambassador. London displeased him, and in 1790 he returned to France, and plunged into political writing. His prose *Avis au peuple français* (Aug. 24, 1790) was followed by the *Jeu de Paume*, a moral ode addressed to the painter Louis David. Chénier was a member of the Feuillant club, and contributed to the *Journal de Paris* the Iambes addressed to Collot d'Herbois *Sur les Suisses révoltés*. He escaped the massacres of September because his family got him away to Normandy, and after the execution of Louis XVI. he hid in an obscure refuge near Versailles. To this period belong his *Ode à Charlotte Corday* and his *Ode à Versailles*. His lines on the art of writing poetry are still quoted in French university circles.

But on Mar. 7, 1794, he was arrested in the house of Madame Piscatory at Passy. He was lodged first in the Luxembourg and then in Saint-Lazare. His imprisonment lasted 141 days. His brother, Marie-Joseph, a member of the Convention, could not save him, and he was guillotined on July 25, 1794, three days before Robespierre, whose death would have saved him. To this four months' imprisonment belong André Chénier's greatest poems, the *Jeune Captive*, the *Iambes* (in alternate lines of 12 and 8 syllables) attacking the Convention and conveyed sheet by sheet to his friends by a venal gaoler.

These circumstances explain how it was that the greatest French lyricist of the 18th century had to wait 20 years for the merest recognition of his genius. For only fragments of his work were known, and he only reached the full measure of his powers in the months before his tragic end. Only the *Jeu de Paume* and the *Hymne sur les Suisses* were known in his life time. The *Jeune Captive* and the *La Jeune Tarentine* were published in periodicals in 1795 and 1801. The first imperfect attempt to collect the body of his work was made in 1819. Since that date there has been unanimous acknowledgment of his genius, but the critics have been divided as to whether he should be classed, as Sainte-Beuve classed him, as the forerunner of Victor Hugo and the romanticists, or, as Anatole France would have it, as the last exponent of the art of the 18th century. Perhaps his influence was greatest on the classicists who led the reaction against the romanticists at the end of the 19th century, on Leconte de Lisle and Hérédia.

BIBLIOGRAPHY.—The Chénier literature is enormous. His fate has been commemorated in numerous plays, pictures and poems, notably in the fine epilogue of Sully Prudhomme, the *Stello* of A. de Vigny, the delicate statue by Puech in the Luxembourg, and the well-known portrait in the centre of the "Last Days of the Terror." The best editions are still those of Becq de Fouquières (1862, 1872 and 1881), supplemented by those of L. Moland (2 vols. 1889) and R. Guillard (2 vols. 1899).

See also Sainte-Beuve, *Tableau de la Litt. fr.* (1828); Anatole France, *La Vie littéraire* vol. ii.; E. Faguet, *André Chénier* (1902).

CHÉNIER, MARIE-JOSEPH BLAISE DE (1764–1811), French poet, dramatist and politician, younger brother of André de Chénier, was born at Constantinople on Feb. 11, 1764. He was brought up at Carcassonne, and educated in Paris at the Collège de Navarre. After two years spent in the army he began to write plays on the Voltairian model. The notoriety attained by the later plays was due to political considerations rather than to any intrinsic literary merit. His *Charles IX.* was kept back for nearly two years by the censor; its production (Nov. 4, 1789) was an immense success, due in part to Talma's magnificent impersonation of Charles IX. Camille Desmoulins said that the piece had done more for the Revolution that the days of October, and a contemporary memoir-writer, the marquis de Ferrière, says that the audience came away "ivre de vengeance et tourmenté d'une soif de sang." The performance occasioned a split among the actors of the Comédie Française, and the new theatre in the Palais Royal, established by the dissidents, was inaugurated with *Henri VIII.* (1791), generally recognized as Chénier's masterpiece; *Jean Calas, ou l'école des juges* followed in the same year. In 1792 he produced his *Caius Gracchus*, which was proscribed in 1793 at the instance of the Montagnard deputy, Albitte, for

an anti-anarchical hemistich (*Des lois et non du sang!*); *Fénelon* (1793) was suspended after a few representations; and in 1794 his *Timoléon*, set to Étienne Méhul's music, was also proscribed. This piece was played after the fall of the Terror, but the fratricide of Timoléon became the text for unfounded insinuations that, by his silence, Joseph de Chénier had connived at the judicial murder of André. In fact Joseph knew that André's only chance of safety lay in being forgotten by the authorities, and that intervention would only hasten the end. Joseph Chénier had been a member of the Convention and of the Council of Five Hundred, and had voted for the death of Louis XVI.; he had a seat in the tribunate; he belonged to the committees of public instruction, of general security and of public safety. Nevertheless, before the end of the Terror he had become a marked man. His purely political career ended in 1802, but from 1803 to 1806 he was inspector-general of public instruction. *Cyrus* (1804) was written in honour of Napoleon, but Chénier was temporarily disgraced in 1806 for his *Épître à Voltaire*. He died on Jan. 10, 1811. The list of his works includes hymns and national songs—among others, the famous *Chant du départ;* odes, *Sur la mort de Mirabeau, Sur l'oligarchie de Robespierre,* etc.; tragedies which never reached the stage, *Brutus et Cassius, Philippe deux, Tibère;* a *Tableau historique* (1808) of contemporary French literature; translations from Sophocles and Lessing, from Gray and Horace, from Tacitus and Aristotle; with elegics, dithyrambics and Ossianic rhapsodies.

See *Œuvres complètes de Joseph Chénier* (8 vols., 1823–26), containing notices of the poet by Arnault and Daunou; Charles Labitte, *Études littéraires* (1846); Henri Welschinger, *Le Théâtre révolutionnaire, 1789–1799* (1881); and A. Lieby, *Étude sur le théâtre de Marie-Joseph Chénier* (1902).

CHENILLE, a twisted velvet cord, woven so that the short outer threads stand out at right angles to the central cord, thus giving a resemblance to a caterpillar. Chenille is used as a trimming for dress and furniture. The word is French and means a hairy caterpillar.

CHENONCEAUX, a village of central France, in the department of Indre-et-Loire, on the right bank of the Cher, 20 mi. E. by S. of Tours on the Orléans railway. Pop. (1946) 222. Chenonceaux owes its interest to its château, a building in the Renaissance style on the river Cher. Founded in 1515 by Thomas Bohier (d. 1523), financial minister in Normandy, the château was confiscated by Francis I. in 1535. An isolated tower flanking a drawbridge is part of an earlier building of the 15th century. Henry II. presented it to Diane de Poitiers, who on his death was forced to exchange it for Chaumont-sur-Loire by Catherine de' Medici. The latter built the gallery which leads to the left bank of the Cher. Chenonceaux passed successively into the hands of Louise de Vaudémont, wife of Henry III., the house of Vendôme, and the family of Bourbon-Condé. It came into the possession of Claude Dupin (1684–1769) and in 1864 it was sold to the chemist Théophile Pélouze, whose wife executed extensive restorations.

CHENOPODIUM or Goosefoot, a genus of erect or sometimes prostrate herbs of the family Chenopodiaceae, comprising some 60 species, natives of temperate regions, some of which have cosmopolitan distribution as weeds. Inclusive of those introduced from the old world, some 25 species occur in North America. A well known representative is the common goosefoot (*C. album*), called also lamb's quarters and pigweed. It is native to Europe and Asia, is found in Great Britain, and is widely prevalent in North America as a naturalized weed. The green angular stem is often striped with white or red, and, like the leaves, often more or less covered with mealy particles. The leaves are entire, lobed or toothed and often more or less triangular in shape. The minute flowers are borne in dense axillary or terminal clusters. The fruit, usually enclosed by the persistent calyx, is a membranous utricle covering a small, black, often glossy seed.

Among other goosefoots found in Great Britain and also naturalized in North America are the maple-leaved goosefoot (*C. hybridum*), the nettle-leaved goosefoot or sowbane (*C. murale*), the oak-leaved goosefoot (*C. glaucum*), the many-seeded goosefoot (*C. polyspermum*), the city goosefoot (*C. urbicum*), and good-King-Henry (*C. Bonus-Henricus*). Other old-world species naturalized in North America are the Jerusalem oak (*C. Botrys*), the Mexican tea (*C. ambrosioides*) and the wormseed (*C. anthelminticum*).

Among native North American species are the red goosefoot (*C. rubrum*), growing on saline soils on sea coasts and in the interior, and found also in Europe; the strawberry blite (*C. capitatum*), with fleshy red fruit clusters somewhat resembling strawberries, native to dry soil from Nova Scotia to Alaska southward to New Jersey and California, and also in Europe; and the California goosefoot or soap plant (*C. californicum*), found in the foothills of the Sierra Nevada and coast ranges, the grated roots of which are used as soap by the Indians.

Quinoa (*C. Quinoa*), native to the Andean region, is cultivated in South America for its seeds, used as food. The wormseed (*q.v.*) yields a drug used as a vermifuge. (*See* the article Good-King-Henry.)

CHEOPS, in Herodotus, the name of the king who built the Great Pyramid in Egypt. Following on a period of good rule and prosperity under Rhampsinitus, Cheops closed the temples, abolished the sacrifices and made all the Egyptians labour for his monument, working in relays of 100,000 men every three months (*see* Pyramid). He even sacrificed the honour of his daughter in order to obtain the money to complete his pyramid; and the princess built herself besides a small pyramid of the stones given to her by her lovers. Cheops reigned 50 years and was succeeded by his brother, Chephren, who reigned 56 years and built the second pyramid. During these two reigns the Egyptians suffered every kind of misery and the temples remained closed. Herodotus continues that in his own day the Egyptians were unwilling to name these oppressors and preferred to call the pyramids after a shepherd named Philition, who pastured his flocks in their neighbourhood At length Mycerinus, son of Cheops and successor of Chephren, reopened the temples and, although he built the Third Pyramid, allowed the oppressed people to return to their proper occupations.

Cheops, Chephren and Mycerinus are historical personages of the fourth Egyptian dynasty, in correct order, and they built the three pyramids attributed to them here. But they are wholly misplaced by Herodotus. Rhampsinitus, the predecessor of Cheops, appears to represent Rameses III. of the twentieth dynasty, and Mycerinus in Herodotus is but a few generations before Psammetichus, the founder of the twenty-sixth dynasty. Manetho correctly places the great Pyramid kings in Dynasty IV. In Egyptian the name of Cheops (Chemmisor Chembis in Diodorus Siculus, Suphis in Manetho) is spelt Hwfw (Khufu), but the pronunciation, in late times perhaps Khöouf, is uncertain. How far we may accept Herodotus' view of the distress caused by the building of the pyramid is doubtful. Petrie thinks that he can trace a violent religious revolution with confiscation of endowments at this time in the temple remains at Abydos; but none the less the deities were then served by priests selected from the royal family and the highest in the land. Khufu's work in the temple of Bubastis is proved by a surviving fragment, and he is figured slaying his enemy at Sinai before the god Thoth. In late times the priests of Denderah claimed Khufu as a benefactor; he was reputed to have built temples to the gods near the Great Pyramids and Sphinx (where also a pyramid of his daughter Hentsen is spoken of), and there are incidental notices of him in the medical and religious literature. The funerary cult of Khufu and Khafrē was practised under the twenty-sixth dynasty, when so much that had fallen into disuse and been forgotten was revived. Khufu is a leading figure in an ancient Egyptian story (Papyrus Westcar), but it is unfortunately incomplete. He was the founder of the fourth dynasty, and was probably born in Middle Egypt near Beni Hasan, in a town afterwards known as "Khufu's Nurse," but was connected with the Memphite third dynasty. Two tablets at the mines of Wadi Maghara in the peninsula of Sinai, a granite block from Bubastis, and a beautiful ivory statuette found by Petrie in the temple at Abydos, are almost all that can be definitely assigned to Khufu outside the pyramid at Giza and its ruins

accompaniments. His date, according to Petrie, is 3969–3908 B.C., but in the shorter chronology of Meyer, Breasted and others he reigned (23 years) about a thousand years later, *c.* 2900 B.C.

See Herodotus ii. 124; Diodorus Siculus i. 64; Sethevin Pauly-Wissowa's *Realencyklopädie, s.v.;* W. M. F. Petrie, *History of Egypt,* vol. i., and *Abydos,* part ii. p. 48; J. H. Breasted, *History.*

CHEPSTOW, market town, urban district and river port of Monmouthshire, England, on the Wye, 2 mi. above its junction with the Severn, and on the Western Region railway. Pop. (1951) 5,285. Area, 2.41 sq.mi. As the key to the passage of the Wye, Chepstow (*Estrighorel, Striguil*) was the site of British, Roman and Saxon fortifications. The Norman castle was built by William Fitz-Osbern to defend the Roman road into south Wales. The castle occupies a hill site on the western bank of the river. It was founded in the 11th and rebuilt in the 13th century. It was granted by Henry I to Walter FitzRichard of Clare, and after its reversion to the crown, Edward II granted it to Thomas de Brotherton. It passed, through Margaret, Lady Segrave, to the dukes of Norfolk, from whom, after again reverting to the crown, it passed to the earls of Worcester. It was confiscated by parliament but restored to the earls in 1660. The church of St. Mary, originally the conventual chapel of a Benedictine priory, has some old features. The borough must have grown up between 1310, when the castle and vill were granted to Thomas de Brotherton, and 1432, when John, duke of Norfolk, died seised of the castle, manor and borough of Striguil. In 1524 the earl of Worcester granted a new charter to the bailiffs and burgesses of the town, which had fallen into decay. This was sustained until the reign of Charles II, when, some dispute arising, the charter lapsed and the town was afterwards governed by a board of twelve. A port since early times, when the lord took dues of ships going up to the forest of Dean, Chepstow had no ancient market and no manufactures but that of glass, which was carried on for a short time within the ruins of the castle. A local trade during the 19th century was handicapped by the narrowness and depth of the channel and the consequent tidal bore. There is a racecourse 1½ mi. N.W. of the town.

CHEQUE or **CHECK.** A cheque, in the simple definition of the English law, "is a bill of exchange drawn on a banker payable on demand." It has proved in practice to be a credit instrument of astonishing usefulness. No one could have foreseen that the cheque would become the chief currency of domestic commerce in Great Britain and the United States. What is perhaps equally surprising is that the British and American example has not been more largely followed in other countries. Over 90 per cent of the internal financial and wholesale trading transactions of Great Britain and the United States are settled by cheque. On the continent of Europe the cheque system is comparatively undeveloped, but it is everywhere making headway, especially in France and Germany. That the cheque will eventually come into universal use cannot be doubted.

The word "cheque," of which "check" is a variant, originally signified the counterfoil or indent of an exchequer bill, or any draft form of payment, on which was registered the details of the principal part, as a "check" to alteration or forgery. The check or counterfoil parts remained in the hands of the banker, the portion given to the customer being termed a "drawn note" or "draft." From the beginning of the nineteenth century the word "cheque" gradually became synonymous with "draft" as meaning a written order on a banker by a person having money in the banker's hands, to pay some amount to bearer or to a person named. Ultimately, the word "cheque" entirely superseded the word "draft."

The law relating to cheques, which is generally one with that of bills of exchange, but has some different and supplemental points, is dealt with elsewhere (*see* BILL OF EXCHANGE). Here we note some of the chief precautions which should be used in drawing cheques.

Cheque Forms.—London banks use a form printed "or order" the payees cannot obtain the money without "endorsing" the cheque. Therefore no other person could obtain the money without committing forgery. Further, the form may be printed "crossed"; two lines being printed across it. A cheque so crossed can only be cashed through a banker, so that, if we imagine the endorsement to be forged, the forger could not cash the cheque without the aid of a person with a banking account to put the cheque through for him. Further, the drawers of the cheque often take the precaution of adding the words "a/c Payees only" to the crossing. That means that no person other than the payees could obtain payment, even though a forger had signed the payee's name on the back.

In drawing cheque for eight pounds, for example, the words should be carefully written close to the printed words "the sum of," and also close to each other, to prevent the insertion of forged figures, while the space not needed for words is filled in with a thick wavy line. The "t" of "eight" and the "p" of pounds, are written closely together to prevent the insertion of a "y" to turn "eight" into "eighty." For the same reason, the figures are carefully written and the spaces between them filled with lines. As a further precaution, the words "under nine pounds" are written in the top left hand corner. A cheque thus drawn with care and intelligence can hardly be misused, but business firms often take the further precaution of using a machine which perforates the figures as it prints them. A cheque may legally be drawn upon a plain piece of paper, but this, fortunately for the bankers, is rarely done; it is only too likely to lead to mistake and loss. The adoption of an inimitable form of signature by those who draw many cheques should be carefully considered. It is a curious fact that wholly or partly illegible signatures are much safer than those carefully or very legibly written, for a well or beautifully written name is easily imitated by the forger.

Bankers issue to their customers on request cheque-forms either to "bearer" or to "order," and printed either crossed or left uncrossed. It is far the best way to use cheque forms printed "or order" and crossed. If it is desired to make the cheque payable to "bearer" this can be done by crossing out the word order and signing the alteration. Again, if it is desired to cancel the printed cross lines this can be done by writing across them "Pay cash" and signing the alteration.

The usual form of an American cheque carries at the top the date of issuance, the name of the bank on which it is drawn and a number for convenient identification. This is followed by the printed words "Pay to the order of" and a space in which is written the name of the payee. On the next line the amount in dollars is written out and the cents usually shown in figures. There is also provided a place for writing the whole amount of the cheque in figures. At the bottom appears the signature of the maker. To collect the cheque the payee must endorse it exactly as his name is written. When so endorsed the cheque is good in the hands of anyone, as is the case with a cheque made payable to cash. The signature of the person cashing it is usually required. The precautions stated above should be used in drawing the cheque.

The Cheque as Receipt.—The cheque form has come into common sense use as a means of giving a receipt conveniently and expeditiously. It is not surprising that it occurred to business men that as a cheque has to be endorsed on the back by the payee, it would make short work of detail by turning that endorsement into a definite receipt for the money paid. Accordingly, in an increasing number of cases, business firms print on the back of the cheques they use a form of a receipt for the payee to sign. As cheques are always sent back to the drawers when cleared by their bankers, the drawers have only to paste the returned cheques in their cheque book to have a complete and combined record of payments and receipts. A further development of the cheque form has naturally followed. The custom of endorsing a cheque on the back is a strange one. To find such an endorsement one has to turn the cheque over, and it is never well in matters of record to write or print on both sides of the paper. The endorsement on the back of a cheque, useful as it is, is thus seen as a combination of usefulness and inconvenience. Realising this, some business houses have boldly brought the endorsement on to the front of the cheque and at the same time made it a receipt form. This somewhat enlarges the size of the cheque form, but

the complete record can be contrived within a space of 7 or 8 in. by 5 or 6 in. It is probable that so simple and convenient a method of combining payment, endorsement and receipt will come into wide use (*see* BILL OF EXCHANGE; BANKING; MONEY MARKET).

CHEQUERS. Chequers Court, near Wendover, Buckinghamshire, became an official residence of British prime ministers in 1921 through the generosity of its owners, Lord and Lady Lee of Farcham. The estate is about 1,500 ac. in extent.

Here Caractacus had a stronghold, of which the earthworks are still visible. "Radulphus," clerk to the Exchequer, was owner under Henry II., and the place appears to have taken its name from his office. In 1565, his descendant, William Hawtrey, remodelled the house and gave it much of its present character and appearance. In the 18th century, a unique collection (which still remains) of Cromwell portraits and other relics was brought by the Russells, who were descended from one of the Protector's daughters. The Russells maintained the Elizabethan house with little alteration, but Robert Greenhill, who inherited from them early in the 19th century, plastered the whole of the outside and redecorated the interior in Strawberry Hill Gothic fashion.

When the Lees entered on a long tenancy in 1909 they sought to reveal all the remaining ancient features, and to introduce others characteristic of the days of the Hawtreys and the Russells. In 1917 Lord and Lady Lee changed their tenancy into a freehold, and created a trust, which, on their deaths should make the house an adequate seat where the prime ministers could entertain guests. The original draft for the Chequers Trust declared that:—"The main features of the scheme are, therefore, designed not merely to make Chequers available as the official country residence of the prime minister of the day, but to tempt him to visit it regularly, and to make it possible for him to live there, even if his income should be limited to his salary. With this object a sufficient endowment is provided to cover the cost of a permanent nucleus staff of servants, of keeping up the gardens and grounds, of maintenance and repairs, and other necessary outgoings. There is also a residential allowance for the official occupant calculated in a fashion deliberately designed to encourage regular week-end visits." The draft, however, insisted upon the unaltered preservation of both house and contents.

In 1920 Lord and Lady Lee resolved that this scheme should not await their death but should take immediate effect. All the preparations for establishing and working the trust having been completed, the prime minister, Lloyd George, held his housewarming on Jan. 8, 1921. His successors have spent part of their time here during their terms of office and ministerial week ends at Chequers Court became a part of English political life.

CHER, a department of central France, embracing the eastern part of the ancient province of Berry, and parts of Bourbonnais, Nivernais and Orléanais, bounded north by the department of Loiret, west by Loir-et-Cher and Indre, south by Allier and Creuse, and east by Nièvre. Pop. (1946) 286,070. Area 2,820 sq.mi. Oolitic rocks occupy much of the department but are covered by Cretaceous and Tertiary deposits in the north. The higher well-drained land of the south and east is suitable both for cultivation and for pasturage. The valley of the Loire is especially fertile and the eastern, sunny slopes are noted for their vines, particularly in the neighbourhood of Sancerre. Wheat and oats are largely cultivated, while hemp, vegetables and fruits are also produced. The central districts are fertile but are low-lying and marshy, being often flooded by the Cher. The department contains much pasturage whence considerable trade in horses, cattle, sheep and wool for the northern markets. Many parts, also, are well-wooded. The chief rivers, besides the Cher and its tributaries, are the Grande Sauldre and the Petite Sauldre on the north, but the Loire, which forms the eastern boundary, and the Allier, though not falling within the department, drain the eastern districts, and are navigable. The Cher itself becomes navigable when it receives the Arnon and Yèvre, and communication is greatly facilitated by the Canal du Berry, the lateral canal of the Loire, which follows the left bank of that river, and the canal of the Sauldre. Mines of iron are worked and stone is quarried. There are brick, porcelain and glassworks, flour-mills, distilleries, oil-works, saw-mills and tanneries. Bourges and Vierzon are metallurgical and engineering centres. The department is served by the Orléans railway. It is divided into the two *arrondissements* (29 cantons, 290 communes) of Bourges and Saint-Amand-Mont-Rond, of which the former is the capital and the seat of an archbishop and of a court of appeal. The department belongs to the *académie* (educational division) of Paris. Bourges, Saint-Amand-Mont-Rond, Vierzon and Sancerre are the principal towns. Méhun-sur-Yèvre (pop. 4,616 in 1946), a town with porcelain manufactures, has a Romanesque church and a château of the 14th century. The church at St. Satur has a fine choir of the 14th and 15th centuries; those of Dun-sur-Auron, Plaimpieds, Aix d'Angillon and Jeanvrin are Romanesque in style, while that at Aubigny-Ville is of the 12th, 13th and 15th centuries. Drevant, on the site of a Roman town, preserves ruins of a theatre. The Pierre-de-la-Roche, at Villeneuve-sur-Cher, is the most notable megalithic monument.

CHERAT, a hill cantonment and sanatorium in the Peshawar district of the North-West Frontier province, Pakistan, 34 mi. S.E. of Peshawar. It is situated at an elevation of 4,500 ft. It was first used in 1861, and later was employed during the hot weather as a health station for the British troops quartered in the vale of Peshawar.

CHERBOURG, a naval station, fortified town and seaport of northwestern France, capital of an *arrondissement* in the department of Manche, on the English channel, 232 mi. W.N.W. of Paris on the Ouest-État railway. Pop. (1946) 40,042. Cherbourg is situated at the mouth of the Divette, on a small bay at the apex of the indentation formed by the northern shore of the Cotentin peninsula, backed by the steep Montagne du Roule.

Cherbourg is supposed to occupy the site of the Roman station of *Coriallum,* but nothing definite is known about its origin. The peninsula, stretching far towards the Isle of Wight, seems to have been used by prehistoric traders of the bronze age as a starting place for the British Isles. William the Conqueror, under whom the settlement appears as *Carusbur,* provided it with a hospital and a church; and Henry II of England on several occasions chose it as his residence. Under Philip Augustus it became of military importance; in 1295 it was pillaged by an English fleet from Yarmouth, and in the 14th century it frequently suffered during the wars against the English. Captured by the English in 1418 after a four months' siege, it was recovered by Charles VII of France in 1450. An attempt was made under Louis XIV to construct a military port. Fortifications constructed by Vauban in 1686 were dismantled in 1689. Harbourworks were begun under Louis XVI and continued by Napoleon I. It was left, however, to Louis Philippe, and Napoleon III, to complete them. By 1858, £8,000,000 had been expended on the works; in 1889, the harbour was farther extended.

The naval and commercial harbours are distant from each other about half a mile. The former consists of three main basins cut out of the rock, and has an area of 55 acres. The minimum depth of water is 30 ft. Connected with the harbour are dry docks, shipbuilding yards, magazines, rope walks, etc. There is a large naval hospital close to the harbour. The commercial harbour at the mouth of the Divette communicates with the sea by a channel 650 yd. long. It consists of two parts, an outer and tidal harbour 17½ acres in extent, and an inner basin 15 acres in extent, with a depth on sill at ordinary spring tide of 25 ft. Outside these harbours is the triangular bay, which forms the roadstead of Cherbourg. The bay is naturally sheltered on every side but the north, where lies the huge breakwater, 2¼ mi. in length (begun by Louis XVI), with a width of 650 ft. at its base and 3 ft. at its summit, which is protected by forts, and leaves passages for vessels to the east and west. The transatlantic liners lie within this *digue.*

Near the roadstead is the church of La Trinité, a good example of the Flamboyant style (1423–1504), and one of the few historic buildings of Cherbourg. A rich collection of paintings is housed in the *hôtel de ville.* A statue of the painter J. F. Millet, born near Cherbourg, stands in the public garden. Cherbourg is a fortified place of the first class, headquarters of one of the fi

naval arrondissements of France, and the seat of a sub-prefect. It has tribunals of first instance and of commerce, a chamber of commerce and a naval school. The chief industries of the town proper are fishing, sawmilling, tanning, shipbuilding, iron and copper founding and ropemaking. The bathing beach is frequented by local holidaymakers. Cherbourg is a port of call for transatlantic steamers. The chief exports are stone for road-making, butter, eggs and vegetables; the chief imports are coal, timber, superphosphates and wine from Algeria. Great Britain is the principal customer.

CHERBULIEZ, CHARLES VICTOR (1829–1899), French novelist and miscellaneous writer, was born at Geneva, where his father, André Cherbuliez (1795–1874), was a classical professor at the university. He resumed French citizenship and was elected a member of the Academy (1881). Cherbuliez wrote many novels, showing the influence of George Sand, of which the following are the best known: *Le Comte Kostia* (1863), *Le Prince Vitale* (1864), *Le Roman d'une honnête femme* (1866), *L'Aventure de Ladislas Bolski* (1869), *La Vocation du Comte Ghislain* (1888),' *Le Secret du précepteur* (1893), *Jacquine Vanesse* (1898). He also contributed literary and historical studies to the *Revue des deux Mondes* and *Le Temps*, many of which were collected in book form in *L'Allemagne politique* (1870), *Études de littérature et d'art* (1873), *Profils étrangers* (1889), etc.

See E. Ritter, *Victor Cherbuliez* (1900).

CHERCHEL, a seaport of Algeria, in the *arrondissement* and department of Algiers, 55 mi. W. of the capital. Pop. (1948) 7,805. It is in an agricultural and vine-growing district. Commercially it is of no great importance. The artificial harbour gives excellent shelter to small vessels. The town is noted for the extensive ruins of former cities on the same site. Cherchel was a city of the Carthaginians, who named it Jol. Juba II. (25 B.C.) made it the capital of the Mauretanian kingdom under the name of Caesarea. Destroyed by the Vandals, Caesarea regained some importance under the Byzantines. Taken by the Arabs it was renamed Cherchel. Khair-ed-Din Barbarossa captured the city in 1520 and annexed it to his Algerian pashalik. In 1840 the town was occupied by the French. The ruins suffered from vandalism during the early period of French rule, many portable objects being removed to museums in Paris or Algiers, and most of the monuments destroyed for the sake of their stone. The museum contains some of the finest statues discovered in Africa.

See V. F. Godell, *Les monuments antiques de l'Algérie* (1901).

CHEREPOVETZ, a town and district in the Vologda region (*q.v.*) of the Russian Soviet Federated Socialist republic. The area of the district is 18,387 sq.mi., and the populatibn 607,735, mainly rural. The soil is mainly of the podsolized bog type favourable to tree growth (*see* RUSSIA: *Soils and Their Influence*) and 76% of the district is forested. The climate is dry and cold, and the waterways are frozen six months in the year; of the average rainfall of 20 to 25 in., most falls in July and August. The summer temperature averages 65° F. Much timber is exported in a raw state to Leningrad and Moscow or abroad; there is little manufacture of furniture or other wooden goods. The timber is floated down the waterways on rafts when the spring thaws begin. During World War I and the Intervention (1914–21), sawmilling and timber works fell off, partly through the blockade of foreign markets and partly through the cessation of building operations. By 1924 it had reached only 50% of the 1913 level. Koustar (peasant) industries in charcoal burning and the production of pitch and tar are carried on in all the forest areas. Hunting is a profitable occupation, mainly for export. Squirrel, fox, marten and polecat fur have the widest sale; other animals hunted are otter and marsh otter, white hare, ermine, lynx, wolf and brown bear. During the war and civil war 1914–21, hunting practically ceased, and wolves and bears became so numerous that they attacked the villagers, and it was necessary to offer rewards for their heads. By 1925 the export of furs from the area reached two-thirds of the prewar level. In the sown area, the chief crops are rye, oats, barley, wheat and buckwheat, which together form 83.5% of the crops. Potatoes, flax and hay are also produced. In the famine year 1921–22, Cherepovetz had a good harvest, since it is largely under the influence of the western cyclonic system and was unaffected by the eastern drought conditions. Cattle, horses, sheep and pigs are reared and a co-operative system of dairy artels is developed for the supply of Moscow and Leningrad. Of industries other than timber working, only the production of matches and leather goods reached prewar level. Printing, the making of small metal goods and work on electric stations are slightly developed, the respective percentages being 1.6, 2.1 and .9. Roads are poor and in many areas do not exist at all, the only railway is the east to west line which links Leningrad with Vologda, and freightage is mainly by the waterways, especially that linking with the famous Marii network to Leningrad.

The town of Cherepovetz, lat. 59° 8′ N., long. 37° 55′ E., population 24,900, is the administrative centre. It is situated at the junction of the Yagorba and Sheksna rivers, which drain into the Volga, and during the spring thaws the banks of these streams are submerged. The Voskresensk monastery, of ancient foundation, certainly prior to the 15th century, led to a settlement of peasants near it, and this settlement was raised to town rank in 1780 and given the name of Cherepovetz. Its situation on the railway and waterways makes it a centre for the products of the province. Agricultural implements and boots and shoes are made in the town, and there are a brandy distillery and a timber mill.

CHERIBON (Tjerebon), Indonesia, formerly a residency of the island of Java, Dutch East Indies, bounded west by Batavia residency, south by Priangan residency, north by the Java sea, and east by the residency of Pekalongan: it is included in the government of West Java. Pop. (1930) 2,069,690, including 3,379 Europeans and Eurasians, and 36,905 foreign Asiatics, Chinese included. Although some Javanese live in the north, Cheribon is Sundanese country, its eastern boundary dividing the Sundanese from the Javanese territory of Central Java. Cheribon has been for centuries the centre of Mohammedanism in West Java, for it is here that the Mohammedan power was strongly established as early as 1526, under Gunung Jati and much of the opposition to Dutch rule at a later date came from this district. The native population is orderly and prosperous. The northern half of the residency is flat and marshy in places, while the southern half is mountainous. Southwest of the city of Cheribon stands the huge volcano Cherimaj, clad with virgin forest and plantations, and surrounded at its foot by rice fields. Sulphur and salt springs occur on the slopes of Cherimaj, and near Palimanan there is a cavernous hole called Guwagalang (or Payagalang), which exhales carbonic acid gas, and which is considered holy by the natives, and is guarded by priests. The principal products of cultivation are tea, rice, essential oils, sugar, cinchona, cassava and ground nuts and pulses, the tea and other plantations for the most part being owned by Europeans. The chief towns are Cheribon (pop. 54,079 with 1,653 Europeans and Eurasians and 8,191 Chinese), a seaport and the capital, and Indramayu (pop. 21,190). Cheribon has a good open roadstead, and quay and warehouse-accommodation for the lighters into which cargo is discharged. The town is very old and irregularly built; it is a regular port of call. Cheribon was the residence of the powerful sultans of Tjerebon, and their descendants live there still, on pension, the head of the house being styled the Sultan Sepoeh. Kuningan, famous for a breed of horses, is a hill resort (2,200 ft.) much resorted to by Europeans. Imports and exports respectively, in 1939 were, for Cheribon port, 22,636,000 and 9,371,000 guilders. The residency was occupied by Japan in March 1942.

CHERIMOYA or **CHERIMOYER** (*Annona Cherimola*), a sub-tropical fruit of the custard-apple family (Annonaceae), sometimes called Peruvian custard-apple. It is probably native to the mountains of Ecuador and Peru whence several centuries ago it spread by cultivation to Mexico, Central America and the West Indies; later to the Hawaiian islands, Mediterranean countries, Africa, India and Polynesia, and recently to the southern United States. It succeeds best in a comparatively cool and dry summer climate, and in the tropics must be grown at considerable elevation. It does well in protected foot-hill regions of California and also in southern Florida where there is little frost. The fruits

are roundish to oblong conical, grayish-brown or nearly black, three to five pounds or more in weight, with the skin either smooth or with warty tubercles on the surface. The flesh is soft, sweet, rich and deliciously flavoured. Propagating is done by shield budding or cleft grafting on seedling stocks two years old, and stocks of other species of *Annona* are sometimes used. Mature trees are from 15 to 20 ft. high.

CHERKASSY (CHERKASSI), a town in the Kiev region of the Ukrainian S.S.R., 49° 25′ N., 32° 3′ E. Pop. (1939) 51,693. It is situated near the right bank of the Dnieper, at the south-eastern termination of a patch of forest. It has a radio station and is on the north to south railway which links Chernigov with Odessa. The inhabitants (Little Russians) are employed in agriculture and gardening. Sugar and tobacco are manufactured, and there are timber mills and veneering works and factories for nail and brick making. Cherkassy was an important town of the Ukraine in the 15th century, and under Polish rule, until the revolt of the Cossack hetman Chmielnicki (1648). It was annexed by Russia in 1795. German troops occupied it in 1941.

CHERNIGOV, a town and region in the Ukrainian S.S.R. The region has an area of 4,125 sq.mi., and is much smaller than the former Chernigov government. The Dnieper river forms its western boundary; its eastern boundary reaches long. 32° E. in the north, but toward the south is farther west and runs parallel with the left bank of the Desna river. Its northern boundary coincides with that of the Ukraine, and the region of Kiev lies to the south. The northwest between the Dnieper and the Desna is forested, with marshes near the rivers, but the area on the left bank of the Desna lies in the transitional forest-steppe zone. In the northwest lumbering and the production of woodenwares, tar, pitch and leather goods are the main peasant occupations, beekeeping forming a useful supplement. The sown area is small, the marshy and sandy soil being unfavourable to agriculture. The chief crops are rye and oats. Hemp is also cultivated. The Desna river and its tributaries are navigable in summer and form outlets for timber. The climate is severe, the rivers being frozen for about 130 days. The town of Chernigov, lat. 51° 31′ N., long. 31° 20′ E., has an average January temperature of 23° F.; July 68.5° F. Pop. (1939) 67,356. Chief occupations are the making of spirits, leather goods, especially footwear, and flour milling. The town is a river port, with an elevator and a radio station; it is the terminus of a branch railway. It has had a long and eventful history and was mentioned in the treaty of Oleg, 907, as next in importance to Kiev. In the 11th century it became the capital of the principality of Syeversk, and its cathedral dates from that time. The Mongol invasion, 1239, destroyed its prosperity. In the 14th century it was annexed by Lithuania, and as a part of the grand duchy of Lithuania entered in union with the kingdom of Poland and remained a part of the Polish-Lithuanian state until its occupation by the Russians in 1686. It was occupied by the Germans in 1941.

CHERNOV, VICTOR MIKHAILOVICH (VICTOR OLIENIN) (1876–1952), cofounder and leader of the Russian Social Revolutionary party, joined the revolutionary movement in 1893. He became a member of the party's central committee and editor of *Revolutionary Russia.* At the Zimmerwald conference of 1915 he supported the "defeatist" resolution of the party's left wing condemning the "imperialist war." After the revolution of March 1917 he returned to Russia and changed to a "defender" (*oboronets*) of his country against the German imperialist war. He edited the journal *Dielo Naroda* and opposed the left wing of the party and the Bolsheviks. He became minister of agriculture in the provisional coalition government of May 18, 1917, and was author of a project of radical legislation on agrarian reform. In September, however, he resigned after the anarchist peasant movement had seized lands from their owners. He was elected president of the Russian constituent assembly, which opened on Jan. 18, 1918, and, after one session, was dispersed by the Bolsheviks. During the civil war Chernov fought against the Reds and the Whites on the Volga. In 1918 he emigrated to Paris and devoted himself to literary work. At the outbreak of World War II he went to the United States, where he contributed to anti-Communist periodicals (notably *Sotsialisticheskii Vestnik*). He died in New York city on April 15, 1952.

CHERNYSHEVSKY, NIKOLAY GAVRILOVICH (1828–1889), Russian writer and political leader, was born at Saratov. His first works dealt with literary criticism (*The Aesthetic Relations of Art to Reality,* 1855, and *Studies of the Age of Gogol*). In the reform movement which set in after the Crimean War, he took an active part. His journal, the *Contemporary,* urged a program of education, more railways and a "rational distribution of economic forces"—in other words, emancipation of the serfs. On this last point he laid particular stress, and when the tsar Alexander put forward his first reform program (Jan. 1858), Chernyshevsky in the *Contemporary* ranked him higher than Peter the Great. The incompleteness of the agrarian reform, when promulgated, and the delays in its execution ended in turning Chernyshevsky against the government, and he and Dobrolyubov became the leaders of the Radical party which demanded immediate and wholesale reform. A visit to Hertzen in London convinced Chernyshevsky of the futility of the liberal movement and resulted in a rupture between the Liberals and Radicals. Chernyshevsky, now supported by the Nihilists, increased his agitation till his sudden arrest in 1862. He was tried in 1864 and sent for 24 years to Siberia. During his imprisonment in the fortress of St. Petersburg he had written his famous novel *Shto Delat (What Is to Be Done?,* 1863; Eng. trans. under the title *The Vital Question,* 1866)—a classic of the revolutionary movement which earned him his severe sentence. In 1883 he was transferred from north Siberia to Astrakhan, where he began to translate Weber's *Universal History.* In 1889 he was allowed to return to Saratov, where he died, broken in health, a few months after.

See G. Plekhanov, *N. G. Tschernyschewsky* (Stuttgart, 1894).

CHEROKEE. This tribe, of Iroquoian lineage, is one of the largest in the United States. They inhabited the southern Alleghenies, where the Carolinas, Georgia, Alabama and Tennessee adjoin. Their name seems to be of Muskogi origin and to mean "cave people." Encountered by De Soto in 1540, they first came into contact with the British in the latter half of the 17th century. They fought on the British side in the American Revolution, refusing to make peace until ten years after its termination. White settlement pressing in upon them, part of the tribe withdrew beyond the Mississippi, but the remainder, in 1820, formed a government modelled on that of the United States and soon after adopted the alphabet, or rather syllabary, invented by one of their half-bloods, Sequoyah. In 1838 the nation was reunited in Indian territory, now Oklahoma, where they were recognized as one of the "five civilized tribes" and set up their capital at Tahlequah, their government remaining effective until 1906, when all Cherokees became United States citizens. Their original numbers were about 15,000, making them one of the largest tribes in North America. Admixture of white and Negro blood, and adoption of aliens of all three races, as well as vigour of the Cherokee stock, have doubled this number. The Cherokee were divided into seven matrilineal clans. Their general culture was similar to that of the tribes of Muskogi stock to the south.

See Royce, *Bur. Am. Ethn. Rep.* v (1887); Mooney, *ibid.,* xix (1902)

CHEROKEE, a city of northwestern Iowa, U.S., on the west bank of the Little Sioux river, 60 mi. E.N.E. of Sioux City; the county seat of Cherokee county. It is a division point on the Illinois Central railroad. The population in 1950 was 7,705; in 1940 it was 7,469 by the federal census. Cherokee is the trade centre for a rich farming, dairying and stock-raising country. The state hospital for the insane is located there.

The first log house in the county was built in 1856, 4 mi. S. of the city, by Robert Perry, who soon thereafter met a colony of emigrants from Milford, Mass., and persuaded them to settle near by. Two black walnut logs from their first stockade are preserved as a historic relic, and the millstones from the first mill have been set up as a monument. When the railway reached the county (1871), the present town site was located about a mile from the old town. Just south of the city is Pilot Rock, a huge glacial boulder, 40 by 60 ft., which was a well-known landmark in the days of migration westward.

CHEROOT, a cigar made from tobacco grown in southern India and the Philippines. The quality of cheroots varies a great deal, but a good example is esteemed for its delicate flavour. A cheroot differs from other cigars in having both ends cut square, instead of one being pointed, and one end considerably larger than the other. Cheroot, which is also sometimes spelled "sheroot," is from the Tamil *shuruttu,* meaning a roll.

CHERRAPUNJI, a village in the Khasi hills district of Assam, India, notable as having one of the heaviest known rainfalls in the world. Its annual average is 429 in., but the fall varies greatly; 905 in. were registered in 1861 (366 in. falling in July) and only 283 in. in 1873. This excessive rainfall is caused by the fact that Cherrapunji stands on the edge of the plateau overlooking the plains, where it catches the full force of the monsoon from the Bay of Bengal.

CHERRY. Next to the peach and the plum the cherry is the most important stone fruit grown in the United States. The horticultural varieties which are of interest for their value as edible fruit belong to two groups, the sweet and the sour. Sweet cherry fruits are used principally for fresh fruit dessert, while the sours make up the great bulk of the frozen and canned cherries of commerce for use in bakeries, restaurants and homes for pies, preserves and sauce. This group is sometimes referred to as pie cherries.

Sweet cherries blossom early in the spring, and the flowers are very susceptible to cold and frost injury. The sour cherry tree is as hardy as some apple varieties, but its flower buds are also quite tender to cold after growth starts in late winter, and crops are frequently lost by freezes occurring near blossoming time. Chiefly because of the special climatic requirements of these two groups, the principal commercial production of sweet cherries in the United States is limited to the Pacific and intermountain states of the west, while the sour cherries are grown principally in districts near the Great Lakes in the states of Michigan, Wisconsin, Ohio, Pennsylvania and New York. However, the sour cherry is also grown as a dooryard or garden tree in many other parts of the country where winter temperatures are not too severe or the summers too hot and dry.

All varieties of cultivated cherry belong to two species. The sweet cherries, *Prunus avium,* are tall pyramidal trees with few or no suckers from the roots and with leaves downy on the underside. The sour cherries, *Prunus cerasus,* are small, broader trees with many suckers from the roots and with fruit sour to bitter in taste. Wild forms of the sweet cherry found growing in the United States and in Europe are also called mazzard, bird and wild sweet cherry.

The native habitat of the sweet cherry species is considered by many authorities to be western Asia, while that of *Prunus cerasus* seems to be close to that of *Prunus avium* in the region about the Caspian sea and extending into eastern Europe. These two species are widely distributed through the north temperate zone. The sweet cherry, *Prunus avium,* has been divided by botanists into different groups, but because of hybridization among the varieties it is rather difficult in many cases to classify them. Sweet cherries with soft, tender flesh form one group known by pomologists under the French group name *guigne* or the English *gean.* This group is also often referred to as the heart cherries. Some of the varieties, such as Wood, are light coloured with colourless juice, while that of others, such as Black Tartarian, are dark coloured with reddish juice. A second group includes those distinguished by the firm, crisp flesh of the fruits and often referred to as the Bigarreaus. Bing, a dark-red cherry, and Napoleon, a light-coloured one, are examples of this group. Like the sweet cherry, the sour cherry is also divided into groups based on the colour of the juice. Cherries with colourless juice are the Amarelles, these having pale red to red fruits more or less flattened at the ends. Montmorency is the most important variety of this group grown in the United States. The Morellos comprise a second group containing varieties such as English Morello, with very dark round to oval fruits and flesh with reddish juice. A group of cherries intermediate in type between the sweets and the sours is known as the dukes. These cherries, which are considered to be hybrids between *Prunus avium* and *Prunus cerasus,* have many characteristics of fruit, skin, flesh, juice colour and flavour, as well as of tree growth, that are intermediate between the sweets and sours. Three other species of cherry of low-growing bush or shrub form with edible fruit are the Nanking or bush cherry, *Prunus tomentosa,* an inhabitant of central Asia; the sand cherry, *P. pumila,* of the shores and beaches of the eastern United States; and the western sand cherry or Bessey cherry, *P. besseyi,* of the western United States.

The cherry is propagated by budding on the wild sweet or mazzard stock, or on the small, wild, inedible, sour cherry of southern Europe, *Prunus mahaleb.* The average annual commercial production of sweet cherries in the United States for the five-year period 1938–42 was slightly more than 79,000 tons, while the average production of sour cherries for the same period was 93,978 tons. In addition to dessert and culinary uses in the home, cherry fruit is also used in the making of liqueurs. Kirschwasser is made chiefly on the upper Rhine from a wild black sweet cherry, *Prunus avium.* Maraschino, a liqueur made from the marasca cherry, is used in Europe and the United States in the making of maraschino cherries. The marasca cherry is a native of the province of Dalmatia, Yugoslavia.

The black cherry, *Prunus serotina,* is native to most of the eastern half of the United States and adjacent areas of eastern Canada. Wood of this species has long been valued by cabinetmakers in making high quality furniture. (F. P. C.)

CHERRY VALLEY, a village of Otsego county, N.Y., U.S., in a township of the same name, 60 mi. N.W. of Albany. Pop. (1950) 760; (1940) 704. It is served by the Delaware & Hudson railway.

Cherry Valley is in the centre of a rich farming and dairying region, has a chair factory and is a tourist resort with sulphur and lithia springs. It was the scene of a terrible massacre during the War of Independence. The village was attacked on Nov. 11, 1778, by Walter Butler (d. 1781) and Joseph Brant with a force of 800 Indians and Tories, who killed about 50 men, women and children, sacked and burned most of the houses and carried off more than 70 prisoners, who were subjected to the greatest cruelties, many dying or being tomahawked before the Canadian settlements were reached.

Cherry Valley was incorporated in 1812.

CHERSIPHRON, a Cretan architect, the traditional builder (with his son Metagenes) of the great Ionic temple of Artemis at Ephesus in the 6th century B.C. Remains of this temple were found by J. T. Wood and brought to the British museum. A fragmentary inscription supports the statement of Herodotus that the pillars were presented by King Croesus.

CHERSO (Cres), one of the three major islands of the Quarnero group, lying off the east coast of the peninsula of Istria, Italy. With the adjacent island of Lussino (Losinj) it was transferred to Italy in the settlement after World War I and was included in Venezia Giulia, while Veglia (Krk), the third member of the group, was attached to Yugoslavia. In 1947 Cherso and Lussino also passed to Yugoslavia.

Cherso, 40 mi. long and 8 mi. wide, has a total area of 125 sq.mi. It is separated from Lussino by a navigable channel, crossed by a swing bridge, the channel being believed to be artificial and the result of Roman work. The Roman town of Ossero (Osor), now a village but formerly the capital of Cherso, stands where the two islands approach most closely. Lussino, though having an area of only 28 sq.mi., has a larger population than Cherso and contains in Lussin Piccolo (Mali Losinj) a harbour of some importance, while Cherso harbour has no great value. Both islands are structurally a part of the karst plateau of Istria, and show similar features, with numerous swallow holes and patches of fertile red earth. Wine, olive oil and fruits are produced in both, but Cherso, which is mountainous, rising to over 2,000 ft., is devoted largely to sheep raising.

Under the Austrians the population of Cherso, about 8,000, was registered as predominantly Serbo-Croat, the Italians forming a minority. But Cherso and Lussino formed together one district, and Italians so largely predominated in the latter island as to make

the total figures for the two stocks practically equal. Since the Italians regarded the Austrian figures as favouring the Serbo-Croat element at their expense the frontier was drawn to include both islands within Italy. In 1947 Cherso was transferred to Yugoslavia.

See "The Austrian Littoral," Foreign Office *Peace Handbook*, 10.

CHERSONESE, CHERSONESUS or **CHERRONESUS,** a word equivalent to "peninsula" (Gr. *χέρσος*, dry, and *νῆσος*, island). In ancient geography the Chersonesus Thracica, Chersonesus Taurica or Scythica, and Chersonesus Cimbrica correspond to the peninsulas of the Dardanelles, the Crimea and Jutland; and the Golden Chersonese is usually identified with the peninsula of Malacca. The Tauric Chersonese was further distinguished as the Great, in contrast to the Heracleotic or Little Chersonese at its southwest corner, where Sevastopol now stands.

History.—The *Tauric Chersonese* (from the 2nd century A.D. called Cherson) was a Dorian colony of Heraclea in Bithynia, founded in the 5th century B.C. in the Crimea about two miles S. of the modern Sevastopol. After defending itself against the kingdom of Bosporus (*see* BOSPORUS CIMMERIUS), and the native Scythians and Tauri, and even extending its power over the west coast of the peninsula, it was compelled to call in the aid of Mithradates VI and Diophantus, *c.* 110 B.C., and submitted to the Pontic dynasty. On regaining a nominal independence, it came under the Roman suzerainty. In the latter part of the 1st century A.D., and again in the 2nd, it received a Roman garrison and suffered much interference in its internal affairs. In the time of Constantine, in return for assistance against the Bosporans and the native tribes, it regained its autonomy and received special privileges. It must, however, have been subject to the Byzantine authorities, as inscriptions testify to restorations of its walls by Byzantine officials. Under Theophilus the central government sent out a governor to take the place of the elected magistrate. Even so it seems to have preserved a measure of self-government and may be said to have been the last of the Greek city states. It had been the main emporium of Byzantine commerce upon the north coast of the Euxine. Through it went the communications of the empire with the Petchenegs and other native tribes, and more especially with the Russians. The commerce of Cherson is guaranteed in the early treaties between the Greeks and Russians, and it was in Cherson, according to Pseudo-Nestor's chronicle (*see* NESTOR), that Vladimir was baptized in 988 after he had captured the city. Its ruin was brought about by the commercial rivalry of the Genoese, who forbade the Greeks to trade there and diverted its commerce to Caffa and Sudak. The constitution of the city was at first democratic under *damiorgi*, a senate and a general assembly. Latterly it appears to have become aristocratic, and most of the power was concentrated in the hands of the first archon or *proteuon*, who in time was superseded by the *strategus* sent out from Byzantium. Its most interesting political document is the form of oath sworn by all citizens in the 3rd century B.C.

Remains.—The remains of the city occupy a space about two-thirds of a mile long by half a mile broad, enclosed by a Byzantine wall. Remains of a Greek wall going back to the 4th century B.C. have been found beneath this in the eastern or original part of the site. Many Byzantine churches, both cruciform and basilican, have been excavated. The latter survived here into the 13th century when they had long been extinct in other Greek-speaking lands. The churches were adorned with frescoes, wall and floor mosaics, and marble carvings similar to work found at Ravenna. The fact that the site has not been inhabited since the 14th century makes it important for our knowledge of Byzantine life. The city was used by the Romans as a place of banishment: St. Clement of Rome was exiled hither and first preached the Gospel; another exile was Justinian II, who is said to have destroyed the city in revenge. Its coins range from the 3rd century B.C. to about A.D. 200, and there are Byzantine issues.

CHERT, in geology, a rock consisting mainly of silica in a finely granular or chalcedonic form, closely allied to flint (*q.v.*). Cherts are probably formed in several different ways; for example, by solution and redeposition of the silica contained in the spicules of sponges and other siliceous organisms in sedimentary rocks, such as the Carboniferous limestone and Upper Greensand of England; by accumulation on the floor of the sea in ancient times of radiolaria and diatoms, like some of the modern deep-sea deposits; by precipitation of silica from magmatic solutions belonging to the later stages of submarine volcanic eruptions. In some instances it is uncertain which of these causes was concerned in their formation. Cherts rich in compounds of iron, of volcanic origin, were the primary source of the iron ore of the Lake Superior region of the U.S. The Rhynie cherts of Devonian age, in Scotland, are noteworthy for the preservation of the minute details of the structure of fossils embedded in them. (R. H. RA.)

CHERTSEY, urban district of Surrey, England, 22 mi. S.W. of London by the Southern Region railway. Pop. (1951) 31,029. Area 15.6 sq.mi. It is pleasantly situated on the right bank of the Thames, which is crossed by a bridge of seven arches, built of Purbeck stone in 1785. The first religious settlement in Surrey, a Benedictine abbey, was founded in 666 at Chertsey (*Cerotesei, Certesey*), the manor of which belonged to the abbot until 1539, when it became a possession of the crown. In the reign of Edward the Confessor Chertsey was a large village and was made the head of Godley hundred. Chertsey owed its importance primarily to the abbey, but partly to its geographical position. Ferries over the Redewynd were subjects of royal grant in 1340 and 1399; the abbot built a new bridge over the Bourne in 1333, and wholly maintained the bridge over the Thames when it replaced the 14th-century ferry. In 1410 the king gave permission to build a bridge over the Redewynd. As the centre of an agricultural district the markets of Chertsey were important and are still held.

Three days' fairs were granted to the abbots in 1129 for the feast of St. Peter ad Vincula by Henry III for Holy Rood day; in 1282 for Ascension day; and a market on Mondays was obtained in 1282.

Little remains of the abbey buildings, which fell into decay in the 17th century. The ground plan, however, can be traced and the fish ponds are complete. Among the abbots the most famous was John de Rutherwyk, who was appointed in 1307, and continued, till his death in 1346, to carry on a great system of alteration and extension. The house in which the poet Cowley spent the last years of his life remains. The town is the centre of a large residential district. Its principal trade is in produce for the London markets.

See Lucy Wheeler, *Chertsey Abbey* (London, 1905); *Victoria County History, Surrey.*

CHERUBIM are winged creatures associated in the Old Testament with the deity. The name, plural of the Hebrew *kĕrūb*, has no Hebrew etymology, and was taken over, with the conception, from older sources. Similar creatures are found in other oriental religions. The cherubim who guard Paradise (Gen. iii, 24) are introduced, without description, as well-known figures. The cherub appears also in Ezek. xxviii, 13–16, behind which passage lies another version of the Paradise story, but the text is too obscure to throw much light on his character. More illuminating is the vision of Ezekiel, ch. i., where the four "living creatures" attendant upon the divine chariot are undoubtedly cherubim, for they are expressly so named in Ezek. x. These have each four wings, and four faces—those of a man, a lion, an ox, an eagle. The two seraphim of Isa. vi belong to the same category, though these have six wings and, presumably, human faces. In Ezekiel and Isaiah these beings are connected with the divine throne. It is thus natural that we should find two gold cherubim covering the "mercy-seat" (Exod. xxxvii, 6–9, xxv, 18–22). Representations of cherubim are found also in the hangings of the shrine (Exod xxvi, 1, 31), and figures of two cherubim, overlaid with gold, in Solomon's temple (1 Ki. vi, 23–28, viii, 6 *seq.*), others carved on

the walls (vi. 29–32), and about the bases of the "molten sea" (vii. 29). So the temple of Ezekiel has carved decorations of cherubim, these with two faces, a man's and a lion's (xl. 18 *seq.*). The description of Yahweh riding "upon a cherub," Ps. xviii. 10, has for its parallel "upon the wings of the wind"; this, although in Babylonian myth the south wind has wings that can be broken, suggests that a mythological conception is used merely for poetical effect, a conclusion confirmed by the similar passage Ps. civ. 3, in which the cherub is replaced by clouds.

To sum up, the cherubim are hybrid creatures, with wings of birds, human or animal faces, regarded as attendants upon the divine throne, or guardians of specially sacred places. The four "living creatures" of Rev. iv. 6 are lineal descendants of those in Ezekiel's vision. In Jewish literature the cherubim appear as a class of angels. Representations of figures similar to the Old Testament cherubim have been discovered in many places, a pair from Dendera showing striking resemblance to those described in Exodus.

See the illustrations in Gressmann's *Altorientalische Texte und Bilder zum Alten Testamente*, nos. 378 *seq.*; Vincent, *Revue Biblique*, p. 487 *seq.* (1926). (W. L. W.)

CHERUBINI, MARIA LUIGI CARLO ZENOBIA SALVATORE (1760–1842), Italian musical composer, was born at Florence on Sept. 14, 1760, and died on March 15, 1842 in Paris. His father was *Maestro al Cembalo* at the Pergola theatre, and began to teach him music when he was six. By the time he was 16 he had composed a great deal of Church music, and in 1777 he went to Bologna, where for four years he studied under Sarti. This famous master well earned the gratitude which afterwards impelled Cherubini to place one of his double choruses by the side of his own *Et Vitam Venturi* as the crown of his *Treatise on Counterpoint and Fugue*, though the juxtaposition does Sarti's music no good. Cherubini also worked at operatic composition, and Sarti sometimes, like the great masters of painting, entrusted his pupil with minor parts of his own works. Cherubini's first complete opera, *Quinto Fabio* was produced in 1780 and was followed in 1782 by *Armida*, *Adriano in Siria*, and other works. In 1784 he was invited to London to produce two works for the Italian opera there, one of which, *La Finta Principessa*, was favourably received while the other, *Giulio Sabino*, was, according to a contemporary witness, "murdered" by the critics.

In 1786 he left London for Paris, which became his home after a visit to Turin in 1787–88 on the occasion of the production there of his *Ifigenia in Aulide*. His first French opera, *Démophon* (1788), which was not a popular success, already marks a departure from the Italian style, which Cherubini still cultivated in the pieces he introduced into the works of Anfossi, Paisiello and Cimarosa, produced by him as director of the Italian opera in Paris (established in 1789). In Paris Cherubini became a great composer. If his melodic invention had been as warm as Gluck's, his masterly technique would have made him one of the greatest composers that ever lived. But his personal character shows in its Johnsonian "anfractuosities" an un-Johnsonian "unclubability," which extends to the centre of his art and deprives even his finest music of the glow of inspiration that fears nothing.

With *Lodoiska* (1791) the series of Cherubini's master-pieces begins, and *Médée* (1797) shows his full powers. Cherubini's creative genius was never more brilliant than at this period, as the wonderful two-act ballet, *Anacreon*, shows; but his temper and spirits were not improved by a series of disappointments which culminated in the collapse of his prospects of congenial success at Vienna, where he went in 1805 in compliance with an invitation to compose an opera for the Imperial theatre. Here he produced, under the title of *Der Wasserträger*, the great work which, on its first production on January 7, 1801 (26 *Nivôse*, *An* 8) as *Les Deux Journées*, had thrilled Paris with the accents of a humanity restored to health and peace. It was by this time an established favourite in Austria. On February 25 Cherubini produced *Faniska*, but the war between Austria and France had broken out immediately after his arrival, and the run of *Faniska* was stopped by the bombardment and capitulation of Vienna.

His stay at Vienna is memorable for his intercourse with Beethoven, the most whole-hearted admirer he and his works have ever met in a century and a quarter. The mighty genius of Beethoven, which broke through all rules in vindication of the principles underlying them, was incomprehensible to Cherubini, in whose mind the creative faculties were finely developed, but whose critical faculty was supplanted by a mere disciplinary code inadequate even as a basis for the analysis of his own works. On the other hand, it would be impossible to exaggerate the influence *Les Deux Journées* had on the lighter parts of Beethoven's *Fidelio*. Cherubini's librettist was also the author of the libretto from which *Fidelio* was adapted, and Cherubini's score was a constant object of Beethoven's study, not only before the production of the first version of *Fidelio* (as *Leonore*) but also throughout Beethoven's life. Cherubini's record of Beethoven's character is contained in the single phrase, "Il était toujours brusque," a fine example of the pot's opinion of the kettle. The overture to *Leonore* merely puzzled Cherubini as to what key it might be in. Beethoven's brusqueness did not prevent him from assuring Cherubini that he considered him the greatest composer of the age and that he loved and honoured him. Cherubini's incapacity to understand Beethoven did not prevent him from working on the grand scale which Beethoven had by that time established as a permanent standard for musical art. The colossal breadth of the duet *Perfides ennemis* in *Médée* is almost inconceivable without the example of Beethoven's C minor trio, op. 1, No. 3, published two years before it. On the other hand the cavatina *Eterno iddio* in *Faniska* is of a terseness and depth not only worthy of Beethoven but surprisingly like him in style.

After Cherubini's disappointing visit to Vienna he did little until 1809 when his friends with much difficulty persuaded him to write a mass for the consecration of a church at the country seat of the prince de Chimay, where he was staying. With this mass (in F, for three-part chorus and orchestra), the period of his great Church music begins; although it was by no means the end of his career as an opera writer, which lasted as late as his 73rd year (1832). This third period is also marked by several instrumental compositions. An early event in the annals of the Philharmonic Society was the invitation of Cherubini to London in 1815 to produce a symphony, an overture and a vocal piece. The symphony (in D) was afterwards arranged, with a new slow movement, as the string quartet in C (1829), a curious illustration of Cherubini's notions of symphonic as well as of chamber-music style, for the quartet-writing is just like that of his other quartets; oil-painting restricted to black and white. Nevertheless the first three of the six string quartets written between 1814 and 1837 are interesting works performed with success at the present day, and the last three, discovered in 1889 are not without fine passages.

At the eleventh hour Cherubini received recognition from Napoleon, who, during the Hundred Days, made him chevalier of the Legion of Honour. Then, with the restoration of the Bourbons, Cherubini's position improved. He was appointed, jointly with Lesueur, as composer and conductor to the Chapel Royal, and in 1822 he obtained the permanent directorship of the conservatoire.

In 1833 Cherubini produced his last work for the stage, *Ali Baba*, adapted (with new and noisy features which excited Mendelssohn's astonished disgust) from a manuscript opera, *Koukourgi*, written 40 years earlier. It is therefore not one of the brighter rockets from what Mendelssohn called "the extinct volcano." But the requiem in D minor (for male voices), written in 1836, is one of Cherubini's greatest works, and, though not actually his last composition, is a worthy close to the long career of an artist of high ideals who, while neither by birth nor temperament a Frenchman, must yet be counted with a still greater foreigner, Gluck, as among the glories of French classical music. Cherubini's *Treatise on Counterpoint and Fugue* embodies his views as a theorist. Concerning one 16th century idiom, as natural in pure polyphony as "attraction of the relative" is in classical Greek. Cherubini remarks, "No tradition gives us any reason why the classics thus faultily deviated from the rule." On

another point where there is a fine opportunity for stimulating a sense of harmonic values, he inculcates a mechanical pseudo-logic with the remark that "The opinion of the classics appears to me erroneous, notwithstanding that custom has sanctioned it, for on the principle that the discord is a mere suspension of the chord, it should not affect the nature of the chord. But since the classics have pronounced judgment we must of course submit." On the whole Cherubini's career as a teacher did more harm than good in his lifetime, and his *Treatise on Counterpoint and Fugue* continues at the present day to invest disastrous misinterpretations of classical art forms with the authority of a great composer.

And yet as a composer Cherubini was no psuedo-classic but a really great artist. His purity of style rarely joined itself to matter that could express the ideals he kept always in view. In his love of those ideals there was too much fear: but Beethoven's estimate of him is more just than the contemptuous neglect with which his art is treated now.

His principal works are summarized by Fétis as 32 operas, 29 Church compositions, four cantatas and several instrumental pieces, besides the treatise on counterpoint and fugue.

Good modern full scores of the two Requiems and of *Les Deux Journées* (the latter unfortunately without the dialogue, which, however, is accessible in a careful German translation in the *Reclam Bibliothek*), and also of ten opera overtures, are current in the Peters edition. Vocal scores of some of the other operas are not difficult to get. The great Credo is in the Peters edition, but is becoming scarce. The string quartets are in Payne's *Miniature Scores*. It is very desirable that the operas, from *Démophon* onwards, should be republished in full score.

CHÉRUEL, PIERRE ADOLPHE (1809–1891), French historian, was born at Rouen. His most important work was done on the history of France in the 17th century. Among his books are *Histoire de l'administration monarchique en France depuis l'avènement de Philippe-Auguste jusqu'à la mort de Louis XIV.* (1855); *Dictionnaire historique des institutions, moeurs et coutumes de la France* (1855); *Journal d'Olivier Lefèvre d'Ormesson* (1860–62); editions of the *Lettres du cardinal Mazarin pendant son ministère* (6 vols., 1870–91), continued by the vicomte G. d'Avenel; of the *Mémoires du duc de Saint-Simon* (1856–58 and 1878–81); *Notice sur la vie et sur les mémoires du duc de Saint-Simon* (1876); *Histoire de la France pendant la minorité de Louis XIV.* (4 vols., 1880) and *Histoire de la France sous le ministère de Mazarin* (3 vols., 1882–83).

CHERUSCI, an ancient German tribe occupying the basin of the Weser to the north of the Chatti (*q.v.*). Together with the other tribes of western Germany they submitted to the Romans in 11–9 B.C., but in A.D. 9 Arminius, one of their princes, rose in revolt, and defeated and slew the Roman General Quintilius Varus, annihilating his army. Germanicus Caesar (*q.v.*) made several unsuccessful attempts to bring them into subjection again. By the end of the 1st century A.D. their prestige had declined, and their territory was eventually occupied by the Saxons.

CHERVONETZ, the new Russian monetary unit, instituted in 1922 as part of the New Economic Policy. The old pre-World War I rouble had, owing to heavy war expenditure, the military-Communist era of 1917–22 and to post-war heavy budget deficits (balanced deliberately by fresh note emissions), depreciated to vanishing point. When the Soviet Government realized the need of a stable currency they instituted the chervonetz.

The chervonetz equals 10 pre-war roubles of 2s. 1½d. Chervonetz notes were issued by the new State bank, having a backing of 25% in gold, platinum or stable foreign exchange, the remaining 75% cover to consist of marketable goods, short-term securities or approved bills of exchange. These notes were from their inception restricted in their issue, so as to maintain the above provisions, and in particular steps were taken to discourage them from entering into internal circulation. They were used as the basis of the nation's currency system and foreign exchange rates were quoted in chervontsi.

Side by side with the chervonetz a new series of rouble notes was issued intended for internal use. These had no fixed conversion ratio against the chervonetz, and for the two years immediately succeeding their first appearance they were issued freely to balance successive budget deficits. Hence they in turn rapidly depreciated until the conversion ratio reached the astronomical figure of 200,000,000,000 roubles to one chervonetz.

In 1924 it proved possible to balance the budget and so to reorganize the internal currency. New currency rouble notes were issued, their volume being limited to half that of the chervontsi in circulation. Simultaneously the old Soviet or 1923 roubles were gradually withdrawn.

After 1924 the internal currency of the country consisted of stable rouble, currency notes and subsidiary coins. (*See* also ROUBLE.)

CHESAPEAKE AND DELAWARE CANAL, in the United States, connects Chesapeake City, Md., and Delaware City, Del., and provides a water route directly across Delaware and Maryland from Delaware bay to Chesapeake bay. It is 19 mi. long, 250 ft. wide and 27 ft. in depth. Its total cost was about $10,000,000.

CHESAPEAKE AND OHIO CANAL, in the United States, between Cumberland, Md., and Washington, D.C., was used formerly for the transportation of coal from the Cumberland region to the Potomac river.

The cost of construction with improvements was about $14,000,000. It is 184 mi. long, 68 ft. wide and 6 ft. in depth. The canal is no longer used for navigation.

CHESAPEAKE BAY, an arm of the Atlantic ocean on the east coast of the United States, is about 200 mi. long and varies in width from 4 to 40 mi.; the lower part of the bay cuts northward through the state of Virginia, and the upper part almost bisects Maryland.

The entrance to the bay is between Cape Charles on the north and Cape Henry on the south.

The Susquehanna river enters the head of the bay in the north; other tributaries include the Nanticoke, Choptank and Chester rivers on the east and the James, York, Rappahannock and Potomac rivers on the west. There are many inlets on the irregular shores of the bay.

The chief port is Baltimore, Md., at the head of the Patapsco river, one of the numerous deepwater estuaries. Oysters and crabs and Potomac herring, perch and other fish are found in great abundance in the waters of the bay. The bay area became a popular recreational centre.

The English settlers who founded Jamestown (*q.v.*) in May 1607 had anchored off Cape Henry in April of that year.

In the summer of the following year, Capt. John Smith began to explore Chesapeake bay and its tributaries. His party covered about 3,000 mi. in its search for data.

CHESELDEN, WILLIAM (1688–1752), English surgeon, was born at Somerby, Leicestershire, on Oct. 19, 1688. He studied anatomy in London under William Cowper (1666–1709), and in 1713 published his *Anatomy of the Human Body*. He became surgeon at St. Thomas's and St. George's hospitals, London. Cheselden is famous for his "lateral operation for the stone," which he first performed in 1727. He was one of the most famous and rapid operators in the preanaesthetic period. He also effected a great advance in ophthalmic surgery by his operation for the treatment of certain forms of blindness by the production of an "artificial pupil."

He attended Sir Isaac Newton in his last illness, and was a friend of Alexander Pope and of Sir Hans Sloane. He died at Bath on April 10, 1752.

See F. H. Garrison, *History of Medicine*, p. 343 (1929).

CHESHAM, an urban district and market town of Buckinghamshire, England, 26 mi. W.N.W. of London by the Eastern Region railway. Pop. (1951) 11,428. Area, 5 sq.mi. It

is pleasantly situated in the narrow valley of the river Chess, flanked by low wooded chalk hills. St. Mary's church, which has some ancient frescoes, is mainly Perpendicular in style. Dairy utensils, chairs, malt-shovels, etc., are made of beech. Shoemaking is also carried on. Waterside, adjoining the town, has duck farms and extensive watercress beds, for which the Chess is noted.

CHESHIRE, a north-western county of England, bounded north by Lancashire, north-east by Yorkshire and Derbyshire, south-east by Staffordshire, south by Shropshire, west by Denbighshire and Flint, and north-west by the Irish Sea. Area 1,014.6 sq. m. The coast-line is formed by the estuaries of the Dee and the Mersey, which are separated by the low rectangular peninsula of Wirral. The Dee forms a great part of the county boundary with Denbighshire and Flint, and the Mersey the boundary along the whole of the northern side. The principal river within the county is the Weaver, which crosses it on a north-westerly course, and receiving the Dane at Northwich, discharges into the estuary of the Mersey south of Runcorn. The surface of Cheshire is mostly low and gently undulating or flat: the broken line of the Peckforton hills, seldom exceeding 600 ft. in height, is conspicuous. The northern part of the hills coincides approximately with the district called Delamere Forest, formerly a chase of the earls of Chester, and finally disforested in 1812. Southwards, commanding the narrow gap of the Gowy river on the west stands the Norman castle of Beeston. Distributed over the county, but principally in the eastern half, are many small lakes or meres, such as Combermere, Tatton, Rostherne, Tabley, Doddington, Marbury and Mere.

With the exception of some Carboniferous rocks on the eastern border, and a small patch of Lower Lias near Audlem, the whole county is occupied by Triassic strata. The great central plain is covered by Keuper Marls, rich grassland loams with many beds of rock-salt, mostly thin, though two are from 75 ft. to over 100 ft. thick. Thin beds and veins of gypsum are common in the marls. The striking features of the Peckforton Hills, which run north and south, bordering the valley of the Weaver on the west, are due to the repeated faulting of the Lower Keuper Sandstone, which lies upon beds of Bunter Sandstone. Besides forming this well-marked ridge, the Lower Keuper Sandstone, which is quarried in several places, forms several ridges north-west of Macclesfield and appears along the northern border and in the neighbourhood of New Brighton and Birkenhead. It is a good building stone and an important water-bearing stratum. At Alderley Edge ores of copper, lead and cobalt are found. West of the Peckforton ridge, Bunter Sandstones and pebble beds extend to the border. They also form low foothills between Cheadle and Macclesfield. They fringe the northern boundary and appear on the south-eastern boundary as a narrow strip of hilly ground near Woore. From Macclesfield northward through Stockport is a narrow tongue of coal-measures—an extension of the Lancashire coalfield. Coal is mined at Neston in the Wirral peninsula from beneath the Trias; it is a connecting link between the Lancashire and Flintshire coalfields. Glacial drift with northern erratics is thickly spread over all the lower ground; at Crewe the drift is over 400 ft. thick. Patches of drift sand, with marine shells, occur on the high ground east of Macclesfield at an elevation of 1,250 ft. The Cheshire lowland filled with prehistoric swamp and forest has not yielded large finds of ancient objects. A list of perforated stone axes is given in *Trans. Lancs. and Ches. Ant. Soc.*, vol. v., p. 327 (*see* also vol. xi., p. 171). Tranmere has yielded a stone-celt retaining part of its wooden handle. Copper was mined at some early period at Alderley Edge and stone hammers with a groove for attachment occur here. The type occurs in Shetland, Wales, South-West Ireland, Brittany, the Iberian Peninsula, Savoy, Austria and Egypt; it is well-known in the New World and the Cambridge Museum has specimens from Australia. A flat celt of copper or bronze is known from Grappenhall. Broxton has yielded one of the few trunnion celts of Britain (*see* Hemp, W. J. *Antiq. Journ.*, vol. v. 1925, p. 51) together with two palstaves and a spearhead. A dagger blade and a pommel have been found at Wilmslow and the surface of the upper Forest bed at Meols has yielded antiquities apparently of the Early Iron Age.

History.—The earliest recorded historical fact is the capture of Chester by the Northumbrian king Aethelfrith about 614. After a period of incessant strife between Britons and Saxons the district was subjugated in 830 and incorporated in the kingdom of Mercia. During the 9th century Aethelwulf held his parliament at Chester, and received the homage of his tributary kings from Berwick to Kent, and in the 10th century Aethelflaed rebuilt the city, and erected fortresses at Eddisbury and Runcorn. Edward the Elder garrisoned Thelwall and strengthened the passages of the Mersey and Irwell. On the splitting up of Mercia in the 10th century the dependent districts along the Dee were made a shire for the fortress of Chester. The shire is first mentioned in the Abingdon *Chronicle,* which relates that in 980 Cheshire was plundered by a fleet of Northmen. At the time of the Domesday survey the county was divided into twelve hundreds, exclusive of the six hundreds between the Ribble and the Mersey, now included in Lancashire, but then a part of Cheshire. Of the seven modern hundreds Bucklow alone retains its Domesday name. The hundreds of Atiscross and Exestan have been transferred to the counties of Flint and Denbigh, with the exception of a few townships now in the hundred of Broxton. Cheshire put up a determined resistance to the Conqueror and no Englishman retained estates of importance after the Conquest. It was constituted a county palatine, with an independent parliament consisting of the barons and clergy, and courts and all lands except those of the bishop were held of the earl. During the 12th and 13th centuries the county was impoverished by the constant inroads of the Welsh. In 1264 the castle and city of Chester were granted to Simon de Montfort. Richard II., in return for support made the county a principality, but the act was revoked in the next reign. In 1403 Cheshire was the headquarters of Hotspur. At the beginning of the Wars of the Roses Margaret collected a body of supporters from among the Cheshire gentry, and Lancastrian risings occurred as late as 1464. In 1643, Chester was made the headquarters of the royalist forces, while Nantwich was garrisoned for the parliament, and the county became the scene of constant skirmishes until the surrender of Chester in 1646.

In the reign of Henry VIII. the distinctive privileges of Cheshire as a county palatine were abridged. The right of sanctuary attached to the city of Chester was abolished and justices of peace were appointed as in other parts of the kingdom. An impression of the wealth of the rich agricultural county is to be seen in the numerous half-timbered houses and ancient manor-houses such as Bramhall Hall, near Macclesfield and Moreton Old Hall, near Congleton. The former dates from the 13th and 14th centuries, and contains a handsome panelled hall. Moreton Hall and several others, such as Brereton and Dorfold Halls, are Elizabethan. Vale Hall near Winsford incorporates fragments of a Cistercian monastery founded in 1277. Ecclesiastical architecture is not well represented outside Chester (*q.v.*), but Lower Peover, near Knutsford has a notable half-timbered church of 13th century date, restored in 1852. There is also a fine late Perpendicular church (with earlier portions) at Astbury near Congleton, and the churches of Banbury and Malpas are Perpendicular and Decorated. St. Michael's church and the Rivers chapel at Macclesfield are noteworthy. In the market-place at Sandbach are two remarkable sculptured Saxon crosses.

Agriculture and Industries.—From earliest times the staple products of Cheshire have been salt and cheese. The salt-pits of Nantwich, Middlewich and Northwich were in active operation at the time of Edward the Confessor, and at that date the mills and fisheries on the Dee also furnished a valuable source of revenue. Twelfth century writers refer to the excellence of Cheshire cheese. The trades of tanners, skinners and glovemakers existed at the time of the Conquest, and the export trade in wool in the 13th and 14th centuries was considerable. The soil of the county is varied and irregular; a large proportion is clay. About 75½% of the total area of 638,960 ac. was under cultivation in 1939. Oats were the most important cereal, occupying 35,224 ac., and over 52% of the cultivated land was in permanent pasture. The vicinity of such populous centres as Liver-

pool and Manchester stimulates dairying. The name of the county is given to a particular brand of cheese. Potatoes are by far the most important rootcrop and occupied 16,416 ac. in 1939. The damson is common among fruit trees, while the strawberry beds near Farndon and Holt are celebrated. Market-gardening is pursued in the neighbourhoods of Chester, Wallasey and Altrincham. In the first half of the 19th century the condition of agriculture in Cheshire was notoriously backward. In 1865–66 the county suffered from cattle plague, and at various times since diseases introduced from overseas through Liverpool have ravaged the county. The manufacture of textiles extends from its seat in Lancashire into Cheshire; and the whole northeastern tongue of the county is engaged in branches of the industry, particularly cotton-spinning. Metalworking is important, and embraces shipbuilding (Birkenhead) and galvanized iron products (Ellesmere Port). At Crewe are situated the great workshops of the London, Midland and Scottish railway company, to which the town owes its origin and rise. Chemical industries are of special importance, and are found along the Mersey; they are closely related to the salt industry. The Mersey shore also has machinery and ironworks, flour mills, tobacco and soap-works (Port Sunlight). Much sandstone is quarried, but the mineral wealth of the county lies in coal (around Congleton and Macclesfield) and especially salt.

Some rock salt is obtained at Northwich and Winsford, but most of the salt is extracted from brine both here and at Lawton, Wheelock and Middlewich. Subsidences frequently occur after the brine is pumped out; walls crack and collapse, and houses are seen leaning far out of the perpendicular.

Communications.—The county is well served with railways. The main line of the L.M.S.R. runs north from Crewe to Warrington with branches from Crewe diverging fanwise to Manchester, Chester, North Wales and Shrewsbury. The G.W.R. passes northward from Wrexham to Liverpool and Manchester. The heart of the county is traversed by the Cheshire lines of the L.M.S.R., serving the salt district, and reaching Chester from Manchester by way of Delamere Forest. In the west, between Chester, Connah's Quay and Liverpool, the L.N.E.R. operates. Many experiments in road building have been made in the Wirral. The river Weaver is locked as far up as Winsford, and the transport of salt is thus expedited. In the salt district of the Weaver, subsidence has resulted in the formation of lakes of considerable extent, which act as reservoirs to supply the navigation. Inland navigation is also provided by the Grand Trunk, Shropshire Union and other canals, and many small steamers are in use. The Manchester Ship canal passes through a section of north Cheshire, entering from the Mersey estuary by locks near Eastham, and following its southern shore up to Runcorn, after which it takes a course more direct than the river, and finally enters Lancashire at the junction of the Irwell with the Mersey, near Irlam.

Population and Administration.—The area of the administrative county is 973 sq.mi.; pop. (1951) 1,258,050. Cheshire has been described as a suburb of Liverpool, Manchester and the Potteries, and has been freely colonized from these populous industrial centres. On the short seacoast of the Wirral are found the popular resorts of New Brighton and Hoylake. The movement of population and the importance of the industries of the county have brought about a vast increase of population in modern times. Further movements during World War II raised the population of the whole county by 2% between Sept. 1939 and Feb. 1941. The county contains seven hundreds and four county boroughs, which are Birkenhead, Chester (a city), Stockport and Wallasey. The municipal boroughs are Altrincham, Bebington, Congleton, Crewe, Dukinfield, Hyde, Macclesfield, Sale and Stalybridge. Chester is the county town. There are 24 urban districts and 10 rural districts.

The county is in the North Wales and Chester circuit, and assizes are held at Chester. It has two courts of quarter sessions, and is divided into 17 petty sessional divisions. Cheshire is almost wholly in the diocese of Chester, but small parts are in those of Manchester, St. Asaph and Lichfield. There are nine parliamentary divisions returning one member each, namely Macclesfield, Crewe, Eddisbury, Wirral, Knutsford, Altrincham, Northwich, City of Chester and Stalybridge and Hyde; the county also includes the parliamentary boroughs of Birkenhead and Stockport, returning two members, and Wallasey, which returns one member. The National Trust owned 496 ac. in Cheshire in 1942.

CHESHUNT, an urban district of Hertfordshire, Eng., on the Lea, 16 mi. N. of London by the Eastern Region railway. Pop. (1951) 23,016. Area 13.3 sq.mi. Finds indicate the presence of a Romano-British settlement. There was a Benedictine nunnery there in the 13th century. A mansion in the vicinity, the Great house, belonged to Cardinal Wolsey. Theobalds Park was built in the 18th century. James I died there in the original mansion in 1625, and Charles I set out from there for Nottingham in 1642 at the outset of the Civil War. One of the entrances to Theobalds Park is old Temple Bar, moved from Fleet street, London, 1878. The church of St. Mary is Perpendicular, with modern additions. Cheshunt college (1792) was the successor of a college founded by the countess of Huntingdon in 1768 at Trevecca in Brecknockshire for the education of ministers of the Methodist connection. In 1905 it was converted into a theological college of the Church of England and later became known as Bishop's college. Cheshunt is an important centre of market gardening.

CHESIL BANK (A.S., *ceosol*, pebble bank), a remarkable beach of shingle on the coast of Dorsetshire, England. It is separated from the mainland for 8 mi. by an inlet called the Fleet, famous for its swannery, and continues in all for 18 mi. southeastward from near Abbotsbury, terminating at the so-called isle of Portland. At the Portland end it is 35 ft. above spring-tide level, and 200 yd. wide, while at the landward end the width is 170 yd. and the pebbles decrease in size. This accords with the general movement of shingle along this coast from west to east.

CHESNELONG, PIERRE CHARLES (1820–1899), French public official, was born at Orthez, Basses-Pyrénées. In 1848 he proclaimed himself a Republican. After the establishment of the Second Empire, however, he changed his views, and in 1863 was returned to the chamber as the official candidate for his native place. He at once became conspicuous, both for his eloquence and for his uncompromising clericalism, especially in urging the necessity for maintaining the temporal power of the papacy. In 1869 he was again returned and, devoting himself with exceptional ability to financial questions, was in 1870 appointed to report the budget.

During and after the war, for which he voted, he retired for a while into private life. But in 1872 he was again elected deputy this time as a Legitimist, and took his seat among the extreme right.

He was the soul of the reactionary opposition that led to the fall of Thiers; and in 1873 it was he who, with Lucien Brun, carried to the comte de Chambord the proposals of the chamber. Through some misunderstanding, he reported on his return that the count had accepted all the terms offered, including the retention of the tricolour flag; and the count published a formal denial.

Chesnelong then devoted himself to the establishment of Catho

lic universities and to the formation of Catholic workingmen's clubs. He continued his vigorous polemic against the secularization of the educational system of France from his place in the senate, to which he was elected in Nov. 1876.

See M. de Marcey, *Charles Chesnelong*, etc., 3 vol. (1908); Mgr. Laveille, *Chesnelong, sa vie, son action catholique et parlementaire* (1913).

CHESNEY, CHARLES CORNWALLIS (1826–1876), British soldier and military writer, the third son of Charles Cornwallis Chesney, Bengal artillery, and nephew of Gen. F. R. Chesney, was born in County Down, Ire., on Sept. 29, 1826. Educated at Blundell's school, Tiverton, and afterward at the Royal Military academy, Woolwich, he obtained his first commission as second lieutenant of engineers in 1845, passing out of the academy at the head of his term.

His early service was spent in the ordinary course of regimental duty at home and abroad, and he was stationed in New Zealand during the Crimean War. Among the various reforms in the British military system which followed from that war was the impetus given to military education, and in 1858 Captain Chesney was appointed professor of military history at Sandhurst. In 1864 he succeeded Colonel (afterward Sir) Edward Hamley in the corresponding chair at the Staff college.

Chesney's first published work (1863) was an account of the Civil War in Virginia, which went through several editions. But the work which attained the greatest reputation was his *Waterloo Lectures* (1868), prepared from the notes of lectures orally delivered at the Staff college. Up to that time the English literature on the Waterloo campaign, although voluminous, was made up of personal reminiscences or of formal records, useful records for history rather than the history itself. The French accounts had mainly taken the form of fiction. Chesney's account illustrates both the strategy and tactics which culminated in the final catastrophe, and the mistakes committed by Napoleon are laid bare. For the first time, moreover, an English writer pointed out that the dispositions of Wellington were far from faultless. In the *Waterloo Lectures* the Prussians are for the first time credited by an English pen with their proper share in the victory. The work attracted much attention abroad as well as at home, and French and German translations were published.

Chesney was for many years a constant contributor to the newspapers and to periodical literature, devoting himself for the most part to the critical treatment of military operations and professional subjects generally. Some of his essays on military biography, contributed mainly to the *Edinburgh Review*, were afterward published separately (1874).

In 1868 he was appointed a member of the royal commission on military education, under the presidency first of Earl de Grey and afterward of Lord Dufferin, to whose recommendations were due the improved organization of the military colleges and the development of military education in the principal military stations of the British army.

In 1871, on the conclusion of the Franco-German War, he was sent on a special mission to France and Germany, and furnished to the government a series of valuable reports on the different siege operations which had been carried out during the war, especially the two sieges of Paris. These reports were published in a large volume, which was issued confidentially.

He was consulted by officers of all grades on professional matters, and few did more to raise the intellectual standard of the British officer. He constantly engaged in literary pursuits and managed also to devote a large part of his time to charitable and religious offices.

Chesney died after a short illness on March 19, 1876. He had become lieutenant colonel in 1873, and at the time of his death he was commanding royal engineer of the London district.

CHESNEY, FRANCIS RAWDON (1789–1872), British general and explorer, was the son of Capt. Alexander Chesney, an Irishman of Scottish descent who, having emigrated to South Carolina in 1772, served under Lord Rawdon (afterward marquess of Hastings) in the War of Independence and subsequently received an appointment as coast officer at Annalong, County Down, Ire. F. R. Chesney was born there on March 16, 1789.

Lord Rawdon gave the boy a cadetship at Woolwich, and he was gazetted to the royal artillery in 1805. But though he rose to be lieutenant general and colonel commandant of the 14th brigade royal artillery (1864), and general in 1868, Chesney is chiefly remembered for his connection with the Suez canal and with the exploration of the Euphrates valley, which started with his being sent to Constantinople in the course of his military duties in 1829 and his making a tour of inspection in Egypt and Syria. His report in 1830 on the feasibility of making the Suez canal was the original basis of Ferdinand de Lesseps' great undertaking. (In 1869 De Lesseps greeted him in Paris as the "father" of the canal.)

In 1831 Chesney introduced to the British government the idea of opening a new overland route to India, by a daring and adventurous journey (for the Arabs were hostile and he was ignorant of the language) along the Euphrates valley from Anah to the Persian gulf.

Returning home, Colonel Chesney (as he then was) busied himself to get support for the latter project, to which the East India company's board was favourable. In 1835 he was sent in command of a small expedition, for which parliament voted £20,000, in order to test the navigability of the Euphrates. After encountering immense difficulties from the opposition of the Egyptian pasha, and from the need of transporting two steamers (one of which was lost) in sections from the Mediterranean over the hilly country to the river, they successfully arrived by water at Bushire in the summer of 1836 and proved Chesney's view to be a practicable one.

In the middle of 1837 he returned to England and was given the Royal Geographical society's gold medal, having meanwhile been to India to consult the authorities there. But the preparation of his two volumes on the expedition (published in 1850) was interrupted by his being ordered in 1843 to command the artillery at Hong Kong.

In 1847 his period of service was completed, and he went home to Ireland to a life of retirement. But both in 1856 and again in 1862 he went to the east to take a part in further surveys and negotiations for the Euphrates valley railway scheme, which, however, the government would not take up in spite of a favourable report from the house of commons committee in 1871.

Chesney died on Jan. 30, 1872.

The chief works of Chesney are: *The Expedition for the Survey of the Rivers Euphrates and Tigris* (1850); *Observations on . . . Fire-arms* (1852); *The Russo-Turkish Campaigns of 1828 and 1829* (1854); *Narrative of the Euphrates Expedition* (1854).

See *The Life of Gen. F. R. Chesney* by his wife and daughter, ed. by S. Lane-Poole (1885).

CHESNEY, SIR GEORGE TOMKYNS (1830–1895), English general, brother of Col. C. C. Chesney, was born at Tiverton, Devon, on April 30, 1830. Educated at Blundell's school, Tiverton, and at Addiscombe, he entered the Bengal engineers as second lieutenant in 1848. He was employed for several years in the public works department. On the outbreak of the Indian Mutiny in 1857, he joined the Ambala column, was field engineer at the battle of Badli-ke-serai, brigade major of engineers throughout the siege of Delhi, and was severely wounded in the assault.

In 1860 he was appointed head of a new department in connection with the public works accounts. His work on *Indian Polity* (1868), dealing with the administration of the several departments of the Indian government, attracted wide attention and became a permanent textbook.

The originator of the Royal Indian Civil Engineering college at Cooper's Hill, Staines, he was also its first president from 1871 until 1880.

In 1871 he contributed to *Blackwood's Magazine*, "The Battle of Dorking," a vivid account of a supposed invasion of England by the Germans after their victory over France. The article was republished in many editions and translations and produced a profound impression.

Chesney was promoted to lieutenant colonel in 1869; colonel, 1877; major general, 1886; lieutenant general, 1887; colonel commandant of royal engineers, 1890; and general, 1892.

From 1881 to 1886 he was secretary to the military department of the government of India and was made a Companion (of the Order) of the Star of India and of the Indian Empire. From 1886 to 1892, as military member of the governor general's council, he carried out many much-needed military reforms.

He was made a Companion of the Bath at the jubilee of 1887, and a Knight Commander of the Bath on leaving India in 1892. In that year he was returned to parliament, in the Conservative interest, as member for Oxford, and was chairman of the committee of service members of the house of commons until his death on March 31, 1895.

Chesney wrote some novels, including *The Dilemma, The Private Secretary* and *The Lesters.*

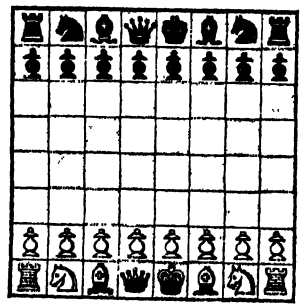
CHESNUT, JAMES (1815–1885), U.S. senator and Confederate soldier, was born at Camden, S.C., on Jan. 18, 1815, the son of the owner of large plantations in Kershaw county, S.C. Chesnut was graduated from Princeton university in 1835 and admitted to the bar in 1837.

In 1840 he was elected to the lower house of the South Carolina legislature as a representative from Kershaw, and he served there, with the exception of the terms of 1846–47 and 1848–49, until 1852. Chesnut then became a state senator, serving as president of the senate from 1856 to 1858, when he was elected a U.S. senator. In the senate Chesnut, who had been graduated from Princeton with an honorary oration, soon became known as an eloquent defender of the institution of slavery.

After resigning from the U.S. senate on Nov. 10, 1860, he helped draw up the ordinance of secession at the South Carolina convention and the permanent constitution at the provisional congress of the Confederate states.

An aide to Gen. Pierre Beauregard during the Ford Sumter incident and at the first battle of Manassas, Chesnut later served as a colonel of cavalry under Jefferson Davis.

In April 1864 he became commander, with the rank of brigadier general, of the reserve troops in South Carolina.



After the war he participated in state politics and was a delegate to state and national conventions of the Democratic party.

He was married to Mary Boykin Miller, whose father, Stephen D. Miller, was governor of South Carolina from 1828 to 1830, on April 23, 1840.

Chesnut died near Camden on Feb. 1, 1885.

CHESS, a game for two players using a board and special pieces. From its pre-eminence among intellectual pastimes, it is called "the royal game." Probably originating in India during or before the 7th century (see *Origin of Chess,* below), chess spread to Persia, Arabia and thence to western Europe. Its name and the term "checkmate" derive from the Persian *shah,* "king," and *shah mat,* "the king is dead." The growth of an extensive occidental chess literature and the rise of international tournaments have standardized the game throughout European and American countries, but variants have survived in Japan and China.

The Board.—The chessboard comprises 64 squares, coloured alternately light and dark, in a large square. The players, designated White and Black, sit on opposite sides. In printed diagrams the Black side is by convention at the top. The board is placed so that each player finds a light square in the corner nearest his right hand. A row of eight squares parallel to the White and Black sides is called a *rank;* a row at right angles to the ranks is a *file.* The term *diagonal* is self-explanatory.

QR QKt QB Q K KB KKt KR

FIG. 1.—DIAGRAM SHOWING POSITION OF CHESSMEN AT BEGINNING OF GAME

Queen's rook (QR); queen's knight (QKt); queen's bishop (QB); queen (Q); king (K); king's bishop (KB); king's knight (KKt); king's rook (KR). The pieces in front of the principal pieces are the pawns (P)

The Pieces.—Each player has 16 pieces, which are placed on the board at the beginning of a game as shown in fig. 1. The pieces are distinguished by their shapes into six kinds: king, queen, rook, bishop, knight, pawn. The king moves in any direction, one square at a time. The queen, rook and bishop are "long-range" pieces, moving any distance along an unobstructed line. The rook moves only on the ranks and files, the bishop only on the diagonals. The queen combines the powers of rook and bishop, and thus moves on any open line. The knight move is from one corner to that diagonally opposite, in a rectangle three squares by two (*see* fig. 2). This is not a line move, but a move from point to point, and therefore cannot be obstructed by any neighbouring pieces. The term "piece" is often used in a restricted sense to exclude pawns. Any piece not a pawn captures in the same way it moves; that is, it may capture an adverse man standing on a square to which it can legally move. The capturing piece replaces the captured on the same square, and the captured man is removed from the board.

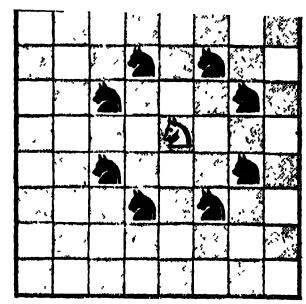


FIG. 2.—DIAGRAM SHOWING THE MOVE OF A KNIGHT

The White knight may move onto any of the squares occupied by the Black knights

The pawn has several peculiarities. It moves only forward, and when not capturing advances only on the file. For the first advance from its initial square on the second rank, the pawn has the option of moving one or two squares, but thereafter may move only one square at a time. If it reaches the eighth rank, farthest from the owner, the pawn is immediately replaced by a queen, rook, bishop or knight of the same colour, at the option of the owner. This *promotion* is also called *queening,* since the usual choice is a queen, the most powerful piece. A pawn may promote even though the piece chosen to replace it has not previously disappeared from the board by capture; *e.g.,* a player may have two or more queens. The pawn alone captures differently from its noncapturing move. It captures to either square that is adjacent and diagonally forward. If a pawn makes the double advance for its first move, an adverse pawn that could have captured it, had the first pawn moved only one square, may capture it *en passant,* in passing; but this "e.p." capture may be made only on the immediate turn, not later.

Castling is a compound move of the king and one rook that may be made, if at all, only once in a game. It is legal if neither the king nor the rook has yet moved; if all the squares between them on the rank are vacant and no adverse piece commands the two squares nearest the king; and if the king is not in check. The move is executed by moving the king two squares toward the rook, and then placing the rook on the square passed over by the king. Either the KR or the QR may be used in castling.

Notations.—In the descriptive notation (*see* fig. 3), each file is given the name of the piece originally posted on it, and the ranks are numbered from 1 to 8 away from the player. Each rank thus has a dual designation, according to the colour of the moving piece. A move is written in the form "P—QB4," the initial of the moving piece followed by the designation of the square moved to. The abbreviation "Kt" for knight is often replaced by "S" or "N." Indication of K—side or Q—side is omitted when no ambiguity would result; *e.g.,* "B—B4" when only one bishop can reach either of the B4 squares. The symbol "×" as in "P×P" indicates a capture and is read "takes." This notation was condensed in the middle 19th century from the earlier floric style; *e.g.,* "King's pawn to his fourth."

In the algebraic notation, each file and rank has a single designation, a letter and a number. A move is written in the form "Pc2—c4" or "c2—c4" or "c4." The initial for the pawn is usually omitted, as is also, in condensed style, the square of departure. Symbols used are as follows: (:) takes; (o–o) castles on K—side; (o–o–o) castles on Q—side; (†) or (+) check; (‡ or (#) checkmate; (!) best, or a good move; (?) questionable, o a poor move; (!?) is this best?

Game records are kept in columnar form, as below. The moves are numbered serially, both a White move and the Black reply having the same number.

Descriptive		Algebraic	
White	Black	White	Black
P—K4	P—K4	1 e2—e4	e7—e5
Kt—KB3	Kt—QB3	2 Sg1—f3	Sb8—c6
B—B4	B—B4	3 Bf1—c4	Bf8—c5
P—B3	Kt—B3!	4 c2—c3	Sg8—f6!
P—Q4	P×P	5 d2—d4	e5—d4:
P×P	B—Kt5ch	6 c3—d4:	Bc5—b4†

In annotation, moves are written linearly, thus: (Descriptive) 1 P—K4, P—K4; 2 Kt—KB3, Kt—QB3; 3 B—B4, B—B4; 4 P—QKt4, B×P; 5 P—B3. (Algebraic) 1 e4, e5; 2 Sf3, Sc6; 3 Bc4, Bc5; 4 b4, Bb4:; 5 c3. Occasionally, the descriptive notation is written in fractional form, the White moves being above the line and the Black moves below, thus:

$$1\ \frac{\text{P—K4}}{\text{P—K4}}\quad \frac{\text{2Kt—KB3}}{\text{Kt—QB3}}.$$

In French and German, respectively, the names of the pieces are: king, *roi, König;* queen, *dame, Dame;* rook, *tour, Turm;* bishop, *fou, Läufer;* knight, *cavalier, Springer;* pawn, *pion, Bauer;* the game is chess, *les échecs, Schach.*

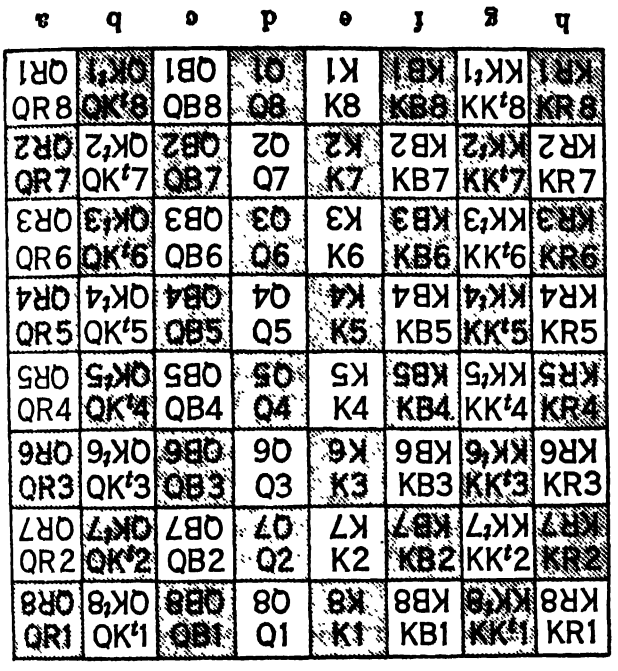

FIG. 3.—DESCRIPTIVE AND ALGEBRAIC SYSTEMS OF NOTATION
The descriptive system names the file after the piece on the first rank, as the "KR file" at the extreme right. The ranks are counted away from the player whose piece moves. In the algebraic system the files are lettered a to h, from White's left to right, and the ranks are numbered 1 to 8 from White to Black. In diagrams the bottom edge is always the White side

Object of Play.—The game is won by capturing the adverse king. The capture is never consummated; when the king is attacked and cannot escape, he is said to be *checkmated* and the game ends forthwith. Many games end by resignation of a player who sees that he cannot escape eventual defeat.

A threat to capture the adverse king is a *check,* and on making such a threat the player by custom says "Check!" The warning is not legally obligatory. A check must of course be averted or the game forfeited. The only ways of meeting a check are to move the king, capture the attacker or interpose on the line of check given by a distant queen, rook or bishop.

Check *by discovery* may be given by a long-range piece, by removal of a piece standing on a line between it and the adverse king. A piece that cannot move without discovering check upon its own king is said to be *pinned.* Even if completely immobilized by pin, a piece may exert check on the adverse king, for if the captures were actually consummated, the pinned piece would capture the adverse king one move ahead of the loss of its own king.

Value of the Pieces.—With only the kings otherwise left on the board, checkmate can be forced by a single "major piece," queen or rook, or by two bishops, or by a bishop and a knight, but not by two knights or any single "minor piece." (But a king accompanied by "officious friends," pawns that block rather than protect him, is sometimes mated by a single knight or bishop. *See* Problem No. 1, below.) A single pawn cannot give mate, but wins if it can be promoted. Two rooks normally draw against a queen, and may win. Two bishops can draw against a queen. But a queen wins against one rook or two minor pieces including a knight. One minor piece draws against a rook.

With additional pieces on the board, however, any "material superiority," even one pawn, spells potential victory. The superior fighting power can usually increase its own margin of advantage. In terms of the pawn as 1, the fighting power of the pieces is approximately: knight 3, bishop 3, rook 5, (king 5), queen 9. This scale gives a measure of whether material equality is disturbed by an exchange of captures of unlike pieces. The phrase "winning the exchange" is applied particularly to winning a rook for a minor piece, or two minor pieces for a rook. Any such gain in relative power is potentially decisive. The more disparate the pieces exchanged, however, the more the outcome is affected by the particular position. For example, the merits of one rook *v.* five pawns cannot be stated in general, as there is no "general position." Positional considerations often override the abstract evaluations. *Sacrifices* of material are often made for positional advantage. The knight and bishop are rated equal, but a bishop is more often favoured by the position than a knight, and two bishops are almost always markedly stronger than two knights.

Drawn Games.—A game may be abandoned as drawn for any of the following reasons. *Insufficient force:* The pieces remaining on the board do not suffice to force checkmate. *Stalemate:* The player in turn to move has no legal move but is not in check. *Perpetual check:* A player demonstrates that he can check the adverse king without cessation, and declares that he will do so. *Agreement:* The players agree to abandon the game (in tournaments, allowed only after Black has completed 30 moves). *Recurrence:* If the same position of all forces recurs three times, with the same player to move on each occasion, that player may claim a draw. *Fifty-move rule:* If during 50 moves on each side, no pawn has moved and no capture has been made, either may claim a draw, unless his opponent can demonstrate a forced checkmate or unless the position is one which is known theoretically to require more than 50 moves for a forced win.

Laws of Chess.—All countries outside the orient follow the laws of chess promulgated by the Fédération Internationale des Échecs. The principal provisions of the 1944 code are as follows:

White moves first. A completed legal move may not be retracted. A move is completed: in moving a man from one square to another, when the player has removed his hand from the man; in capturing, when the captured man has been removed from the board and the player has removed his hand from the capturing man; in castling, when the player has removed his hand from the rook; in promoting, when the player has replaced the pawn by the selected piece and removed his hand from the latter. A player may touch his own men for purpose of arranging them if he says "I adjust" or words to that effect; he must not touch an adverse piece to arrange, after commencement of play, but may call upon his opponent to do so. Except in arranging, if a player touches one of his own men, he must if possible move it; if he touches an adverse man, he must if possible capture it.

If a player makes an illegal move, and the opponent draws attention to the fact before touching any of his own men, the illegal move must be retracted and: if the move was noncapturing, the player must if able move the same piece; if the move was a capture, the player must if able move the same piece or capture the same piece, at the option of the opponent if he can comply in both ways. If during a game it is proved that an illegal move was made and not retracted, the position existing immediately before the illegal move must be reinstated and play continued from that point; if this position cannot be reinstated, the game is annulled. If a player entitled to direct a move in application of penalty names an illegal move, his right is abrogated. Castling may not be exacted as a penalty. A game is declared forfeited by a player who wilfully upsets the board or disarranges the men; refuses to

comply with a requirement under the laws; refuses to conform to arrangements for the conduct of the game; or exceeds the time limit.

In tournament and match games, time is kept on each player, by separate clocks. Each player must complete 30 moves in his first two hours, 45 in his first three hours and so on by increments of 15 moves per hour. (This rate may be modified by regulations for a particular tournament.) A player's clock is set going as soon as it becomes his turn to move, and he may stop it only after making his move. The White player's clock is started at the time scheduled for commencement of a game, regardless of whether both players are present. A player who arrives more than an hour late (without excuse acceptable to the referee) forfeits the game.

If a game is not finished by the prefixed closing time for the session, it is adjourned. The player in turn to move takes whatever time he wishes for consideration, writes his move on a slip of paper, seals it in an envelope which he hands to the referee, and his clock is then stopped. At resumption of play, the referee sets up the position as it was left, opens the envelope, makes the indicated move and starts the opponent's clock. If the sealed move is illegal, and the mistake cannot be rectified to the satisfaction of the referee, he may declare the game forfeited by the player who sealed the illegal move.

Origin of Chess.—The origin of chess is lost in obscurity. Its invention has been variously ascribed to the Greeks, Romans, Babylonians, Scythians, Egyptians, Jews, Persians, Chinese, Hindus, Arabians, Araucanians, Castilians, Irish and Welsh. Some have endeavoured to fix upon particular individuals as the originators of the game; among others, upon Japheth, Shem, King Solomon, the wife of Ravan, king of Ceylon, the philosopher Xerxes, the Greek chieftain Palamedes, Hermes, Aristotle, the brothers Lydo and Tyrrhene, Semiramis, Zenobia, Attalus (d. *c.* 200 B.C.), the mandarin Hansing, the Brahman Sissa and Shatrenscha, stated to be a celebrated Persian astronomer. Many of these ascriptions are fabulous, others rest upon little authority, and some of them proceed from easily traceable errors, as where the Roman games of *ludus latrunculorum* and *ludus calculorum*, the Welsh recreation of *tawlbwrdd* (throw-board) and the ancient Irish pastime of *fithcheall* are assumed to be identical with chess; so far as the Romans and Welsh are concerned, the contrary can be proved, while from what little is known of the Irish game it appears not to have been a sedentary game at all. N. Bland, in his *Persian Chess* (London, 1850), endeavoured to prove that the Persians were the inventors of chess, and maintained that the game, born in Persia, found a home in India, whence after a series of ages it was brought back to its birthplace. The view which has obtained the most credence, however, is that which attributes the origin of chess to the Hindus. Thomas Hyde of Oxford, writing in 1694 (*De Ludis Orientalibus*), seems to have been the first to propound this theory, but he appears to have been ignorant of the game itself, and the Sanskrit records were not accessible in his time. About 1783–89 Sir William Jones, in an essay published in the second volume of *Asiatic Researches*, argued that Hindustan was the cradle of chess, the game having been known there from time immemorial by the name of *chaturanga;* that is, the four *angas*, or members of an army, which are said in the *Amarakosha* to be elephants, horses, chariots and foot soldiers. As applicable to real armies, the term *chaturanga* is frequently used by the epic poets of India. Sir William Jones's essay is substantially a translation of the *Bhawishya Purana*, in which is given a description of a four-handed game of chess played with dice. A pundit named Rhadhakant informed him that this was mentioned in the oldest law books, and also that it was invented by the wife of Ravan, king of Lanka (Ceylon), in the second age of the world in order to amuse that monarch while Rama was besieging his metropolis. This account claims for chess an existence of 4,000 or 5,000 years. Jones, however, grounded his opinions as to the Hindu origin of chess upon the testimony of the Persians and not upon the above manuscript, while he considered the game described therein to be more modern than the Persian game. Though sure that the latter came from India and was invented there, he admitted that he could not find any account of it in the classical writings of the Brahmans. He laid it down that chess, under the Sanskrit name *chaturanga*, was exported from India into Persia in the 6th century of our era; that by a natural corruption the old Persians changed the name into *chatrang*, but when their country was soon afterward taken possession of by the Arabs, who had neither the initial nor final letter of the word in their alphabet, they altered it further into *shatranj*, which name found its way later into modern Persian and ultimately into the dialects of India.

Anton van der Linde, in his exhaustive work *Geschichte und Litteratur des Schachspiels* (1874), had much to say of the origin theories, nearly all of which he treated as so many myths. He agreed with those who consider that the Persians received the game from the Hindus. The outcome of his studies appears to be that chess certainly existed in Hindustan in the 8th century, and that probably that country is the land of its birth. He inclined to the idea that the game originated among the Buddhists, whose religion was prevalent in India from the 3rd to the 9th century. According to their ideas, war and the slaying of one's fellow men, for any purposes whatever, is criminal, and the punishment of the warrior in the next world will be much worse than that of the simple murderer; hence chess was invented as a substitute for war. Van der Linde was in agreement with Sir William Jones in taking the view that the four-handed game of the original manuscript is a comparatively modern adaptation of the Hindu chess, and he altogether denied that there is any proof that any form of the game has the antiquity attributed to it.

H. J. R. Murray, in his monumental work *A History of Chess*, came to the conclusion that chess is a descendant of an Indian game played in the 7th century.

Altogether, therefore, we find the best authorities agreeing that chess existed in India before it is known to have been played anywhere else. In this supposition they are strengthened by the names of the game and of some of the pieces. *Shatranj*, as Duncan Forbes has pointed out, is a foreign word among the Persians and Arabians, whereas its natural derivation from the term *chaturanga* is obvious. Again *al-fil*, the Arabic name of the bishop, means the elephant, otherwise *alephhind*, the Indian ox. Our earliest authority on chess is Masudi, an Arabic author who wrote about A.D. 950. According to him, *shatranj* had existed long before his time; and though he may speak not only for his own generation but for a couple of centuries before, that will give to chess an existence of more than 1,000 years.

Early and Mediaeval Times.—The dimness which shrouds the origin of chess naturally obscures also its early history. We have seen that chess crossed over from India into Persia and became known in the latter country by the name of *shatranj*. Some have understood that word to mean "the play of the king"; but undoubtedly Sir William Jones's derivation carries with it the most plausibility. How and when the game was introduced into Persia we have no means of knowing.

The Persian poet Firdousi, in his historical poem the *Shahnama*, gives an account of the introduction of *shatranj* into Persia in the reign of Chosroes I. Anushirvan, to whom came ambassadors from the sovereign of Hind (India) with a chessboard and men, asking him to solve the secrets of the game, if he could, or pay tribute. The king asked for seven days' grace, during which time the wise men vainly tried to discover the secret. Finally, the king's minister took the pieces home and discovered the secret in a day and a night. He then journeyed to India with a game of his own invention, *nard*, which the Indians were unable to reconstruct.

Other Persian and Arabian writers state that *shatranj* came into Persia from India, and there appears to be a consensus that may be considered to settle the question. Thus we have the game passing from the Hindus to the Persians and thence to the Arabians, after the capture of Persia by the caliphs in the 7th century, and from them, directly or indirectly, to various parts of Europe, at a time which cannot be definitely fixed, but that was either in or before the 10th century. That the source of the European game is Arabic is clear enough, not merely from the words "check" and "mate," which are evidently from *shah mat* ("the king is dead"), but also from the names of some of the

pieces. There are various chess legends having reference to the 7th and 8th centuries, but these may be neglected as historically useless; and equally useless appear the many oriental and occidental romances which revolve around those two great central figures, Harun al-Rashid and Charlemagne. There is no proof that either of them knew anything of chess or, so far as the latter is concerned, that it had been introduced into Europe in his time. True, there is an account given in Gustavus Selenus, taken from various old chronicles, as to the son of Prince Okar or Otkar of Bavaria having been killed by a blow on the temple, struck by a son of Pippin after a game of chess; and there is another well-known tradition as to the magnificent chessboard and set of men said to have been sent as a present by the empress Irene to Charlemagne. But both tales are not less mythical than the romance which relates how the great Frankish monarch lost his kingdom over a game of chess to Guérin de Montglave; for Van der Linde shows that there was no Bavarian prince of the name of Okar or Otkar at the period alluded to, and as ruthlessly shatters the tradition about Irene's chessmen.

With respect to Harun al-Rashid, among the various stories told which connect him with chess there is one that at first sight may seem entitled to some degree of credit. In the annals of the Moslems by Abulfeda (Abu'l Fida) there is given a copy of a letter stated to be "From Nicephorus, emperor of the Romans, to Harun, sovereign of the Arabs," which (using Forbes's translation), after the usual compliments, runs thus: "The empress (Irene) into whose place I have succeeded, looked upon you as a *Rukh* and herself as a mere Pawn; therefore she submitted to pay you a tribute more than the double of which she ought to have exacted from you. All this has been owing to female weakness and timidity. Now, however, I insist that you, immediately on reading this letter, repay to me all the sums of money you ever received from her. If you hesitate, the sword shall settle our accounts." Harun's reply, written on the back of the Byzantine emperor's letter, was terse and to the point. "In the name of God the merciful and gracious. From Harun, the commander of the faithful, to the Roman dog Nicephorus. I have read thine epistle, thou son of an infidel mother; my answer to it thou shalt see not hear." Harun was as good as his word, for he marched immediately as far as Heraclea, devastating the Roman territories with fire and sword, and soon compelled Nicephorus to sue for peace.

Now the points which give authority to this narrative and the alleged correspondence are that the relations which they assume between Irene and Nicephorus on the one hand and the warlike caliph on the other are confirmed by the history of those times, while, also, the straightforward brevity of Harun's reply commends itself as what one might expect from his soldierlike character.

Still, the fact must be remembered that Abulfeda lived about five centuries after the time to which he refers. Perhaps we may assume that it is not improbable that the correspondence is genuine but that the words *rukh* and *pawn* may have been substituted for other terms of comparison originally used.

As to how chess was introduced into western and central Europe nothing is really known. The Spaniards very likely received it from their Moslem conquerors, the Italians not improbably from the Byzantines, and in either case it would pass northward to France, going on thence to Scandinavia and England. Some say that chess was introduced into Europe at the time of the crusades, the theory being that the Christian warriors learned to play it at Constantinople. This is negatived by a curious epistle of St. Pietro Damiani, cardinal bishop of Ostia, to Pope Alexander II written about A.D. 1061, which, assuming its authenticity, shows that chess was known in Italy before the date of the first crusade. The cardinal, as it seems, had imposed a penance upon a bishop whom he had found diverting himself at chess; and in his letter to the pope he repeats the language he had held to the erring prelate; viz., "Was it right, I say, and consistent with thy duty, to sport away thy evenings amidst the vanity of chess, and defile the hand which offers up the body of the Lord, and the tongue that mediates between God and man, with the pollution of a sacrilegious game?"

Among those who took an unfavourable view of the game may be mentioned John Huss, who, when in prison, deplored his having played at chess, whereby he had lost time and run the risk of being subject to violent passions. Among authentic records of the game may be quoted the *Alexiad* of the princess Anna Comnena, in which she relates how her father, the emperor Alexius, used to divert his mind from the cares of state by playing at chess with his relatives. This emperor died in 1118.

Concerning chess in England there is the usual confusion between legend and truth. Snorre Sturleson relates that as Canute was playing at chess with Earl Ulf, a quarrel arose, which resulted in the upsetting of the board by the latter, with the further consequence of his being murdered in church a few days afterward by Canute's orders. Thomas Carlyle, in *The Early Kings of Norway*, repeats this tale, but Van der Linde treats it as a myth. The *Ramsey Chronicle* relates how Bishop Utheric, coming to Canute at night upon urgent business, found the monarch and his courtiers amusing themselves at dice and chess. There is nothing intrinsically improbable in this last narrative; but Canute died about 1035, and the date, therefore, is suspiciously early. Moreover, allowance must be made for the ease with which chroniclers described other games as chess.

As regards the individual pieces, the king seems to have had the same move as at present, but it is said he could formerly be captured. His "castling" privilege is a European invention; but he formerly leaped two and even three squares, and also to his Kt2. Castling dates no farther back than the first half of the 16th century. The queen has suffered curious changes in name, sex and power. In *shatranj* the piece was called *farz* or *firz* (also *farzan, farzin* and *farzi*), signifying a "counsellor," "minister" or "general." This was latinized into *farzia* or *fercia*. The French slightly altered the latter form into *fierce, fierge* and, as some say, *vierge*, which, if true, might explain its becoming a female. Another and much more probable account has it that whereas formerly a pawn on reaching an eighth square became a *farzin*, and not any other piece, which promotion was of the same kind as at draughts (in French, *dames*), so she became a *dame* or queen as in the latter game, and thence *dama, donna*, etc. There are old Latin manuscripts in which the terms *ferzia* and *regina* are used indifferently.

The queen formerly moved only one square diagonally and was consequently the weakest piece on the board. The immense power she now possesses seems to have been conferred upon her as late as about the middle of the 15th century. It will be noticed that under the old system the queens could never meet each other, for they operated on diagonals of different colours. The bishop's scope of action was also very limited formerly; he could move only two squares diagonally, and had no power over the intermediate square, which he could leap over whether it was occupied or not. This limitation of his powers prevailed in Europe until the 15th century.

This piece, according to Forbes, was called among the Persians *pil*, an elephant, but the Arabs, not having the letter *p* in their alphabet, wrote it *fil*, or with their definite article *al-fil*, whence *alphilus, alfinus, alifiere*, the latter being the word used by the Italians; while the French perhaps get their *fol* and *fou* from the same source. The pawns formerly could move only one square at starting; their powers in this respect were increased about the early part of the 16th century. It was customary for them on arriving at an eighth square to be exchanged only for a *farzin* (queen) and no other piece; the rooks (so called from the Indian *rukh* and Persian *rokh*, meaning "a soldier") and the knights appear to have always had the same powers as at present. As to the chessboards, they were formerly uncoloured, and it is not until the 13th century that we hear of checkered boards being used in Europe.

Development in Play.—The change of *shatranj* into modern chess took place most probably first in France, and thence made its way into Spain early in the 15th century, where the new game was called *Axedrez de la dama*, being also adopted by the Italians under the name of *scacci alla rabiosa*. The time of the first important writer on modern chess, the Spaniard Ruy Lopez de Segura

(1561), is also the period when the latest improvement, castling, was introduced, for his book (*Libro de la invencion liberal y arte del juego del Axedrez*), though treating of it as already in use, also gives the old mode of play, which allowed the king a leap of two or three squares. Shortly afterward the old *shatranj* disappears altogether. Lopez was the first who merits the name of chess analyst. At this time flourished the flower of the Spanish and Italian schools of chess—the former represented by Lopez, Ceron, Santa Maria, Busnardo and Avalos, the latter by Giovanni Leonardo da Cutri (Il Puttino) and Paolo Boi (Il Syracusano). In the years 1562–75 both Italian masters visited Spain and defeated their Spanish antagonists. During the whole 17th century we find but one worthy to be mentioned, Giacchino Greco (Il Calabrese).

The middle of the 18th century inaugurates a new era in chess. The leading man of this time was François André Danican Philidor. He was born in 1726 and was trained by M. de Kermar, sire de Légal, the star of the Café de la Régence in Paris, which was the centre of French chess until early in the 20th century. In 1747 Philidor visited England and defeated the Arabian player, Phillip Stamma, by 8 games to 1 and 1 draw. In 1749 he published his *Analyse des échecs*, a book which went through more editions and was more translated than any other work upon the game. During more than half a century Philidor travelled much but never went to Italy, the only country where he could have found opponents of first-rate skill. Italy was represented in Philidor's time by Ercole del Rio, Lolli and Ponziani. Their style was less sound than that of Philidor, but certainly a much finer and in principle a better one. As an analyst the Frenchman was in many points refuted by Ercole del Rio ("the anonymous Modenese").

Blindfold chess play, already exhibited in the 11th century by Arabian and Persian experts, was taken up afresh by Philidor, who played on many occasions three games simultaneously without sight of board or men. These exhibitions were given in London, at the Chess club in St. James's street, and Philidor died in that city in 1795. As eminent players of this period must be mentioned Count P. J. van Zuylen van Nyevelt (1743–1826) and the German player J. Allgaier (1763–1823), after whom a well-known brilliant variation of the king's gambit is named. Philidor was succeeded by Alexandre Louis Honoré Lebreton Deschapelles (1780–1847), who was also a famous whist player. The only player who is known to have fought Deschapelles not unsuccessfully on even terms is John Cochrane. He also lost a match (1821) to W. Lewis, to whom he conceded the odds of "pawn and move," the Englishman winning 1 and drawing the 2 others. Deschapelles's greatest pupil, and the strongest player France ever possessed, was Louis Charles Mahé de la Bourdonnais, who was born in 1797 and died in 1840. His most memorable achievement was his contest with the English champion Alexander Macdonnell, the French player winning in the proportion of 3 to 2.

The English school of chess began about the beginning of the 19th century, and Sarratt was its first leader. He flourished until 1820 and was followed by his great pupil W. Lewis, who will be remembered for his writings. His literary career belongs to the period from 1817 to 1848, and he died in 1870. Macdonnell (1798–1835) has been already mentioned. To the same period belong also Captain Evans, the inventor of the celebrated "Evans gambit" (1824), who died at an advanced age in 1872; George Perigal (d. 1854), who played in the correspondence matches against Edinburgh and Paris; George Walker (1803–79), chess editor of *Bell's Life* from 1835 to 1873; and John Cochrane (1798–1878), who met every strong player from Deschapelles down. In the same period Germany possessed but one good player, J. Mendheim of Berlin. The fifth decade of the 19th century is marked by the fact that the leadership passed from the French school to the English. After the death of La Bourdonnais, Fournié de Saint-Amant became the leading player in France; he visited England in the early part of 1843 and successfully met the best English players, including Howard Staunton (*q.v.*); but the latter soon took his revenge, for in Nov. and Dec. 1843 a great match between Staunton and Saint-Amant took place in Paris, the English champion winning by 11 games to 6 with 4 draws. During the succeeding eight years Staunton maintained his reputation by defeating Popert, B. Horwitz and Harrwitz. Staunton was defeated by Adolph Anderssen at the London tournament in 1851, and this concluded his match-playing career.

In the ten years 1830–40 a new school arose in Berlin, the seven leaders of which have been called "the Pleiades." These were Ludwig Bledow (1795–1846), Bilguer (1815–40), Hanstein (1810–50), Mayet (1810–68), Schorn (1802–50), B. Horwitz (1809–85) and von Heydebrand und der Lasa, once German ambassador at Copenhagen. As belonging to the same period must be mentioned the three Hungarian players Grimm, Szen and J. Löwenthal.

Among the great masters since the middle of the 19th century, Paul Morphy (1837–84), an American, has seldom been surpassed as a chess player. His career was short but brilliant. Born in New Orleans, La., in 1837, he was taught chess by his father when only ten years of age, and in two years' time became a strong player. When not quite 13 he played three games with Löwenthal and won two of them, the other being drawn. He was 20 years of age when he competed in the New York city congress of 1857, where he won the first prize. In 1858 he visited England and there defeated Boden, Medley, Mongredien, Owen, Bird and others. He also beat Löwenthal by 9 games to 3 and 2 draws. In the same year he played a match at Paris with Harrwitz, winning by 5 to 2 and 1 drawn; later he obtained a victory over Anderssen. On two or three occasions he played blindfolded against eight strong players simultaneously, each time with great success. He returned to the U.S. in 1859 and continued to play, but with decreasing interest in the game, until 1866. He died in 1884.

Wilhelm Steinitz (1836–1900) took the sixth prize at the London congress of 1862. He defeated Blackburne in a match by 7 to 1 and 2 draws. In 1866 he beat Anderssen in a match by 8 games to 6. In 1868 he carried off the first prize in the British Chess association handicap and in 1872 in the London grand tourney, also defeating J. H. Zukertort in a match by 7 games to 1 and 4 draws. In 1873 he carried off the first prize at the Vienna congress; and in 1876 he defeated Blackburne, winning seven games right off.

In Philidor's age it was considered almost incredible that he should be able to play three simultaneous games without seeing board or men, but Paulsen, Blackburne and Zukertort often played 10 or 12 such games, while as many as 28 and 29 were so played by Alexander Alekhine and M. V. Réti, respectively, in 1925. Again, in 1933, Alekhine played 32 and Koltanowski played 34 in 1937. Then, in 1943, Miguel Najdorf exceeded all performances with 40 at Buenos Aires.

In 1876 England was in the van of the world's chess army. English-born players then were Boden, Burn, Macdonnell, Bird, Blackburne and Potter; while among naturalized English players were Löwenthal, Steinitz, Zukertort (who died in 1888) and Horwitz. This illustrious contingent was reinforced in 1878 by Mason, an Irish-American, who went abroad for the Paris tournament; by Gunsberg, a Hungarian; and later by Teichmann, who also made England his home. English chess flourished under the leadership of these masters, the chief prizes in tournaments being consistently carried off by the English representatives.

Modern British Chess.—The British Chess federation was instituted in 1904, its first congress being held at Hastings in that year, when a British championship, a ladies' championship and a first-class amateur tournament were played. These competitions have been continued annually at the congresses of the federation, with the exception of the World Wars I and II periods and the years 1922 and 1927, when international tournaments were held in England. The holders of the British championship have been W. E. Napier, H. E. Atkins, R. C. Griffith, F. D. Yates, R. H. V. Scott, Sir G. A. Thomas, Sultan-Khan, W. Winter and W. A. Fairhurst.

In 1896 and following years matches between representative players of Great Britain and the United States, respectively, were played by cable, with the following results:

1896. U.S.	won by	4½ games to 3½
1897. Great Britain	" "	5½ " " 4½

1898. Great Britain	won by	5½	games to	4½
1899. U.S.	" "	6	" "	4
1900. U.S.	" "	6	" "	4
1901. Drawn		5 games each		
1902. U.S.	won by	5½	games to	4½
1903. U.S.	" "	5½	" "	4½
1907. Great Britain	" "	5½	" "	4½
1908. U.S.	" "	6½	" "	3½
1909. Great Britain	" "	6	" "	4
1910. Great Britain	" "	6½	" "	3½
1911. Great Britain	" "	6	" "	4

By winning three consecutive matches Great Britain obtained permanent possession of the trophy.

The World Championship.—The strongest players of their time, and therefore regarded by later generations as "world champions" were: 1747–95, François Philidor, France; 1815–20, Alexandre Deschapelles, France; 1820–40, Louis de la Bourdonnais, France; 1843–51, Howard Staunton, England; 1851–58, Adolph Anderssen, Germany; 1858–59, Paul Morphy, United States; 1862–66, Adolph Anderssen, Germany. In 1866 Anderssen was defeated in a match by Wilhelm Steinitz of Austria, who then laid claim to the title "world champion"—rightly, for he was undoubtedly the strongest player of his day. Steinitz successfully defended his title in formal matches against Blackburne, Zukertort, Tchigorin (twice) and Gunsberg. His unparalleled reign of 28 years was brought to a close in 1894, when he was defeated by a young German player, Emanuel Lasker.

Lasker held the title almost as long as Steinitz, whom he defeated again in a return match two years later. Other challengers who failed were Frank Marshall, Siegbert Tarrasch, David Janowski and Carl Schlechter. Recognized as the logical challenger from about 1914 on was José R. Capablanca of Cuba, but a match was not arranged until 1921. With Capablanca leading 4–0, and 10 draws, Lasker resigned the championship, stating that the climate of Havana was dangerous to his health.

Capablanca held the title for six years. In 1927 he lost it to Alexander Alekhine in a struggle lasting nearly three months, at Buenos Aires. The score was 6–3, with 25 draws, the longest title match up to that time.

Alekhine, a Russian who acquired French citizenship, was defeated in 1935 by Max Euwe of the Netherlands, by the score of 9–8 with 13 draws. Two years later he regained the title in a return match, winning 11–6 with 13 draws. Alekhine twice defeated Efrem Bogoljubow in challenge matches, 1929 and 1934. The death of Alekhine in 1946 left the title vacant.

To establish a new champion, a tournament was held in 1948 among five players selected by world opinion as the strongest contenders. It was won by Mikhail Botvinnik of the U.S.S.R. The others were Samuel Reshevsky of the U.S., Max Euwe of the Netherlands, and Vassily Smyslov and Paul Keres, both of the U.S.S.R. In 1951 Botvinnik successfully defended his title in a drawn match with David Bronstein.

The victory of Reshevsky of the U.S. over Miguel Najdorf of Argentina, in a match in 1952, was hailed as establishing an unofficial championship of the western world, to offset the difficulties thrown in the way of a match between Botvinnik and any challenger from the non-Soviet sphere. In 1953 Russian players were permitted to leave the soviet domain to participate in foreign tournaments, and the way was opened for resumption of competition for the championship on a world-wide basis.

Tournaments.—The first modern international tournament was held in London in 1851. Several hundred tournaments were held after that time, and analysis of the game was greatly accelerated by the publication of all the games played in the major events. The principal tournaments from 1929 are as follows:

1929. Carlsbad. (1) Nimzowitsch, (2) Capablanca and Spielmann.
1929. Budapest. (1) Capablanca, (2) Rubinstein, (3) Tartakower.
1929. Barcelona. (1) Capablanca, (2) Tartakower, (3) Colle.
1929. Ramsgate. (1) Sultan-Khan, (2) Price and Michell.
1929. Bradley Beach. (1) Alekhine, (2) L. Steiner, (3) Kupchik and Turover.
1930. Hastings. (1) Capablanca, (2) Vidmar, (3) Yates.
1930. San Remo. (1) Alekhine, (2) Nimzowitsch, (3) Rubinstein.
1930. Frankfurt. (1) Nimzowitsch, (2) Kashdan, (3) Ahues and List.
1930. Liège. (1) Tartakower, (2) Sultan-Khan, (3) Ahues, Colle and Nimzowitsch.
1931. Hastings. (1) Euwe, (2) Capablanca, (3) Sultan-Khan.
1931. Bled. (1) Alekhine, (2) Bogoljubow, (3) Nimzowitsch.
1931. New York city. (1) Capablanca, (2) Kashdan, (3) Kevitz.
1932. Hastings. (1) Flohr, (2) Kashdan, (3) Euwe.
1932. London. (1) Alekhine, (2) Flohr, (3) Sultan-Khan and Kashdan.
1932. Pasadena. (1) Alekhine, (2) Kashdan, (3) Dake, Reshevsky and H. Steiner.
1932. Mexico City. (1) Alekhine and Kashdan, (3) Araiza.
1932. Berne. (1) Alekhine, (2) Euwe and Flohr.
1933. Hastings. (1) Flohr, (2) Pirc, (3) Sultan-Khan and L. Steiner.
1934. Hastings. (1) Flohr, (2) Alekhine and Lilienthal.
1934. Zürich. (1) Alekhine, (2) Euwe and Flohr.
1935. Hastings. (1) Euwe, Flohr and Thomas.
1935. Moscow. (1) Botvinnik and Flohr, (3) Lasker.
1935. Margate. (1) Reshevsky, (2) Capablanca and Thomas.
1935. Orebro. (1) Alekhine, (2) Lundin, (3) Stahlberg and Stoltz.
1936. Hastings. (1) Fine, (2) Flohr, (3) Tartakower.
1936. Bad Nauheim. (1) Alekhine and Keres, (3) Ahues.
1936. Moscow. (1) Capablanca, (2) Botvinnik, (3) Flohr.
1936. Zandvoort. (1) Fine, (2) Euwe, (3) Keres and Tartakower.
1936. Podebrad. (1) Flohr, (2) Alekhine, (3) Flotys.
1936. Nottingham. (1) Botvinnik and Capablanca, (3) Euwe, Fine and Reshevsky.
1936. Amsterdam. (1) Fine and Euwe, (3) Alekhine.
1936. Margate. (1) Flohr, (2) Capablanca, (3) Stahlberg.
1937. Hastings. (1) Alekhine, (2) Fine, (3) Eliskases.
1937. Margate. (1) Fine and Keres, (3) Alekhine.
1937. Ostend. (1) Fine, Grob and Keres.
1937. Kemeri. (1) Flohr, Petrow and Reshevsky.
1937. Semmering-Baden. (1) Keres, (2) Fine, (3) Capablanca and Reshevsky.
1938. Netherlands (A.V.R.O. tournament). (1) Keres, (2) Fine, (3) Botvinnik.
1939. Leningrad-Moscow. (1) Flohr, (2) Reshevsky, (3) Lilienthal, Loewenfisch, Makagonov and Ragozin.
1939. Hastings. (1) Szabo, (2) Euwe, (3) Landau and Pirc.
1939. Margate. (1) Keres, (2) Capablanca and Flohr.
1940. Salzburg. (1) Alekhine, (2) Keres, (3) Schmidt.
1941. Mar del Plata. (1) Stahlberg, (2) Najdorf, (3) Eliskases.
1942. Buenos Aires. (1) Najdorf and Stahlberg, (3) Frydman.
1942. Munich. (1) Stoltz, (2) Alekhine and Lundin.
1942. Mar del Plata. (1) Najdorf, (2) Stahlberg and Pilnik.
1943. Mar del Plata. (1) Najdorf, (2) Stahlberg, (3) Michel.
1943. Sverdlovsk. (1) Botvinnik, (2) Makagonov, (3) Smyslov and Kahn.
1944. Prague. (1) Alekhine, (2) Keres, (3) Katetov.
1944. Mar del Plata. (1) Najdorf and Pilnik, (3) Michel and Guimard.

Chess by Radio.—The first international match to be conducted by radio was that between the United States of America and the Union of Soviet Socialist Republics, Sept. 1–4, 1945. The U.S. team comprised Arnold Denker, Samuel Reshevsky, Reuben Fine, Israel A. Horowitz, Isaac I. Kashdan, Herman Steiner, Albert S. Pinkus, Herbert Seidman, Abraham Kupchik and Anthony E. Santasiere. The Russian team was Mikhail Botvinnik, Vassily Smyslov, Isaac Boleslavsky, Salo Flohr, Alexander Kotov, Igor Bondarevsky, Andrea Lilienthal, Vyacheslav Ragozin, Vladimir Makagonov and David Bronstein. The Russian team won by 15½ to 4½. (See *Illustrative Game No. 11.*)

Fédération Internationale des Échecs.—This body is the central authority for chess matters. Most of the European countries and the U.S. are members. A tournament under the auspices of the federation was held at Budapest in 1926, and the following year a tournament was held at London between teams, each of four players, representing 16 nations attached to the federation. The tournament was won by Hungary with a score of 40 points out of a possible 60. Close behind came Denmark (second) and Great Britain (third). Hungary also won a similar tournament held at The Hague in 1928. The United States won at Prague, 1931; at Folkestone, 1933; at Warsaw, 1935; at Stockholm, 1937. The U.S. was not represented in 1939 at Buenos Aires, where Germany finished first.

Literature of the Game.—The most ambitious of early European writings on chess was the work of a Lombard, Jacobus de Cessolis (Jacopo Dacciesole), whose main object, however, though he gives the moves, etc., was to teach morals rather than chess. He was a Dominican friar and his treatise *Liber de Moribus Hominum et Officiis Nobilium* was written before the year 1300. It was afterward translated into several European languages, and in the year 1474 Caxton, under the title of *The Game and Playe of Chesse*, printed an English translation of the French version.

About 1500 appeared the *Göttinger Handschrift*, a work containing 12 different openings and 30 problems. The author of this manuscript is not known. Of Lucena, a Spanish author who wrote in or about 1497, we are better informed. His treatise, *Repeticion des amores e arte de axedres*, comprises various practical chess matters, including 150 positions, illustrated by 160 well-executed woodcuts. Various of these positions are identical with those in the *Göttinger Handschrift*.

In the 16th century works upon the game were written by Damiano, Ruy Lopez and Horatio Gianutio della Mantia; in the 17th century by Salvio, Polerio, Gustavus Selenus, Carrera, Greco, Fr. Antonio and the authors of the *Traité de Lausanne;* in the 18th century by Bertin, Stamma, Ercole del Rio, Lolli, Cozio, Philidor, Ponziani, Stein, Count P. J. van Nyevelt, Allgaier and Peter Pratt; in the 19th century by J. F. W. Koch and C. F. Koch, Sarratt, John Cochrane, William Lewis, Silberschmidt, Ghulam Kassim and James Cochrane, George Walker, A. Macdonnell, Jaenisch, Petroff, Bilguer, Von der Lasa, Staunton, Kling and Horwitz, Bledow, Dubois, Kieseritzki, Max Lange, Löwenthal, Dufresne, Neumann, Suhle, Zukertort, Preti, Steinitz and others.

English chess owes much to W. Lewis and George Walker. But to Howard Staunton must be ascribed the most important share in creating the later popularity which the game achieved in England. Staunton's first work, *The Chess Player's Handbook*, was published in 1847 and again (revised) in 1848. His other works are: *The Chess Player's Text-Book* and *The Chess Player's Companion* (1849) (the latter being a collection of his own games); the *Chess Praxis* (1860, republished in 1903); his posthumous work, *Chess Theory and Practice*, edited by R. B. Wormald (1876); and various smaller treatises.

The laws of the game as laid down in the *Praxis* formed the basis of the rules adopted by the British Chess association in 1862. Besides editing the *Chess Player's Chronicle* and the *Chess World*, he was the chess editor of the *Illustrated London News* from 1844 till his death in 1874.

BIBLIOGRAPHY.—*Elements of the Game:* E. E. Cunnington, *The Modern Chess Primer* (1920) gives a good grounding in the elements of the game and the student should master its contents. *General Treatises:* (*a*) Elementary: Lawrence H. Dawson, *A Short Guide to Chess* (1923); E. A. Greig, *Pitfalls of the Chess-Board*, rev. by W. A. Fairhurst (1927). (*b*) Fairly advanced: J. Mason, *The Art of Chess* (1913) and *The Principles of Chess* (1923); Emanuel Lasker, *Common Sense in Chess* (1896) and *Chess Strategy* (1922). (*c*) More advanced: J. R. Capablanca, *Chess Fundamentals* (1921); E. O. Znosko-Borowsky, *The Middle Game in Chess* (1922); M. V. Réti, *Modern Ideas in Chess* (1923); A. Nimzowitsch, *Die Blockade* and *Mein System* (1925); Kmoch, *Die Kunst der Verteidigung* (1927); Emanuel Lasker, *Lasker's Manual of Chess* (1927). *End Games:* The elements of the endings are dealt with in both *The Modern Chess Primer* and *The Art of Chess.* Other works which may be recommended to the more advanced student are: R. Fine, *Basic Chess Endings* (1943); Mieses, *Chess Endings from Modern Master-Play;* Tattersall, *A Thousand End-Games;* Rinck, *700 fins de partie* (1926) and Berger's monumental work, *Theorie und Praxis der Endspiele*, 2nd ed. (1921). *Openings:* The best work in English is undoubtedly R. C. Griffith and A. C. White's *Modern Chess Openings* (1925), revised by Reuben Fine (1939), upon the theory of the openings. The *Handbuch des Schachspiels* (8th ed. 1916, by Schlechter, with supplement, 1921, by Mieses) and *Lärobok i Schack* (1921) are decidedly more voluminous but less up-to-date. A mine of information is S. Tartakower's *Die Hypermoderne Schachpartie* (1924). Of works dealing with only one opening the following are useful: J. du Mont, *The Centre Counter* and *The Centre Game;* Maróczy, *Die Französische Partie* (1924); S. Tarrasch, *Die Verteidigung des Damengambits* (Gouda, 1924) and Tartakower, *Die Zukunftseröffnung* (1924); R. Fine, *Ideas Behind the Chess Openings* (1943); J. du Mont, *The Basis of Combination in Chess* (1942).

Collections of Games: A valuable—and, perhaps, the most enjoyable—form of chess study is the careful playing over of well-annotated master games. The following books are recommended: *Mr. Blackburne's Games at Chess* (1899); P. W. Sergeant, *Morphy's Games of Chess* (1916) and *Charousek's Games of Chess* (1919); P. W. Sergeant and W. H. Watts, *Pillsbury's Chess Career* (1923); Maróczy, *Hundert Schachpartien* (1921); J. R. Capablanca, *My Chess Career* (1920); S. Tarrasch, *Dreihundert Schachpartien* (1916) and *Die Moderne Schachpartie* (1916); A Alekhine, *My Best Games of Chess* (1927). A. Alekhine and H. Helms, *New York Tournament* (1924); F. Reinfeld *Keres' Best Games of Chess* (1942); A. Alekhine, *The Nottingham Tournament Book* (1936); F. J. Wellmuth, *The Golden Treasury of Chess* (1943).

History: The best book on the history of the game is H. J. R. Murray, *A History of Chess* (1913). (G. E. S.; H. Hs.; G. Mu.)

Theories of Play.—One of the contributions of François Philidor was to draw attention to the importance of pawns as fighting units. He formulated the classic pattern of attack against the castled king—the advance of pawns to break up the pawns sheltering the enemy king and so open lines for the infiltration of pieces. The hundred years after the publication of his *Analyse des échecs* saw the discovery of a myriad permutations of the so-called "direct attack" and the rise of great masters of combination play, culminating in Adolph Anderssen. (See *Illustrative Game No. 1.*) By "combination" is understood the calculation of specific variations of play, in search of a way to force a more-or-less immediate decision.

The characteristic of the games of this era is the sacrifice, and the dominating motive is the desire to attack as quickly as possible. The analysis of openings was largely concerned with "gambits"—sacrifices of pawns, sometimes pieces, made to precipitate rapid contact with the enemy. It was even held by some that the Evans gambit was the only debut worthy of a gentleman, since this opening is particularly apt to lead to a "slugging contest."

In 1858–59 Paul Morphy created a sensation by trouncing all the masters who would meet him. His play introduced a new note, one that even today is basic in the teaching of beginners. Although second to none in combinative skill, Morphy delayed attacking until he had "completed his development." By simply bringing out his knights and bishops, posting the queen safe from harassment, and castling, Morphy repeatedly achieved a "won game" after a dozen moves. So effective was this procedure against the current fashion of attacking prematurely that it crystallized into a formula: move each centre pawn once, each bishop and knight once, get the queen off the back row, castle—before moving any piece a second time. The task of developing is not actually so easy: the opponent exerts threats that have to be parried. But it remains true that any relative loss of time in the opening can lead to a quick catastrophe. (See *Illustrative Game No. 2.*)

Rapid development, combinative attack—these principles seemed to be all-embracing and all-sufficient. Then came a pugnacious Austrian, Wilhelm Steinitz, whose play often violated classic principles. Yet with it he was able to win the world cham-

pionship and to hold it longer that any other player. Steinitz lived to influence the theory of play more profoundly than any other player. His theories, at first seemingly antithetical to classic principles, were presently seen to be supplementary.

Steinitz started from the premise that there is no combination without positional advantage. That is, a specific winning sequence of moves cannot be found, if there is no superiority on which to base it. The player should therefore concern himself primarily with analyzing the position to detect its points of strength and weakness. On this score, Steinitz contributed a great deal of analysis on the nature of weaknesses, and the specific meaning of permanent as opposed to transient weaknesses. The objective of play, he said, is to gain a decisive positional superiority by "the accumulation of small advantages." An adverse weakness must be "nursed" and magnified until it becomes fatal: then the combination will spring of itself from the position. (See *Illustrative Game No. 4.*)

In pursuit of local advantages, Steinitz often moved the same piece several times in the opening, before completing his development. He demonstrated that the demands of the "close" game are somewhat different from those of the "open" game. It is indeed necessary to develop rapidly if centre pawns are exchanged early, opening lines of attack. But a slower development is feasible if the centre is kept closed; here it is often more important to get a single piece to its most effective post than to move all the pieces off the back row. Especially in his later years, Steinitz preferred to manoeuvre behind the lines before breaking the centre, so as to gain the maximum advantage from the break when it came. (See *Illustrative Game No. 5.*) This "hedgehog" policy forced upon him the necessity of defending accurately and economically against attack by a more-developed opponent, and his games are instructive for the resources of defense. It is said that Steinitz was never so happy as when sustaining a furious onslaught upon his king; proverbial are his remarks "When in doubt, take a pawn" and "A pawn is worth a little trouble."

The slow tempo of the Steinitz campaign was not for every taste, and it remained for Siegbert Tarrasch to show how to quicken it and open lines for direct attack without relinquishing vital positional advantages. Tarrasch made great contributions of his own to the theory. In play as well as in his writings he showed how positional weaknesses may be forced upon a player if he commands less terrain than his opponent. He formulated the theory of the centre. The opening, he said, is to be understood as a fight for control of the squares d4, d5, e4, e5. A piece standing in the centre has its maximum range, and the centre is the vital avenue of communication between the wings of the army. At first the centre must be controlled by pawns, to prevent its occupation by adverse pieces. He has an advantage who controls the greater number or the more advanced of central squares. (See *Illustrative Game No. 6.*)

A consequence of the Steinitz-Tarrasch analysis was that the opening 1 P—K4 came to be played much less in master tournaments, in favour of 1 P—Q4. The latter is the more likely to lead to a close game. The growing body of knowledge of opening variations tends to indicate that White retains the advantage of the first move longer in a close than in an open game. The queen's gambit came to be a dreaded weapon. (See *Illustrative Game No. 7.*) It was said, only half-jocularly, that "After 1 P—Q4, Black's game is in its last throes." However, Black's prospects brightened in the 20th century with the discovery of several new defensive systems.

In 1913 a young Russian master, Aaron Nimzowitsch, published articles assailing some of the cardinal points of the Tarrasch creed. After World War I he published *My System* and other books expounding certain ideas, as "centralization," "overprotection," "the homeopathic process." In definition these ideas do not seem to be out of the Steinitz-Tarrasch tradition, but their realization sometimes involves moves condemned by it. Nevertheless, Nimzowitsch achieved some notable tournament successes, and carried the Tarrasch principle of constraint to the extraordinary length of complete blockade. (See *Illustrative Game No. 8.*) A curious conclusion to be drawn is that, while the actual advance of a pawn wing may prove weakening, the mere inability to advance it at will is a positive weakness, often of decisive moment.

Nimzowitsch is credited with founding the self-styled "hypermodern school," of which the avowed exponents were Richard Réti, S. Tartakower and Efrem Bogoljubow. Réti (d. 1929) stated the principle of this school to be: "The golden rule is that there is no golden rule." Thus, any attempt to formulate its further principles is interdicted! In practice, the hypermoderns often go to great lengths to avoid releasing the tension in the centre, or even advancing the centre pawns at all, until pieces have been brought to bear upon it. This often involves the fianchetto of one bishop or both. (See *Illustrative Game No. 9.*)

The hypermoderns claim José R. Capablanca and Alekhine as exponents of hypermodern play, although both these world champions repudiated any conscious adherence. The Alekhine defense is cited as an example of relying on the evaluation of a particular position rather than upon general principles. After 1 P—K4, Kt—KB3; 2 P—K5, Kt—Q4; 3 P—QB4, Kt—Kt3; 4 P—Q4, White has three pawns in the centre, one being on the fifth rank, while Black has developed only a knight. By all classical precept, Black has wasted valuable time. Yet it has been abundantly demonstrated that Black can quickly catch up by attacking the advanced pawns. (See *Illustrative Game No. 10.*)

Illustrative Game No. 1.—Adolph Anderssen (1818–79) won first place in the first modern international tournament, London, 1851. His games are memorable for their slashing attacks and combinative brilliance. The famous game below was dubbed the "Immortal Partie."

London, 1851

	White Anderssen	Black Kieseritzki		White Anderssen	Black Kieseritzki
1	P—K4	P—K4	13	P—R5	Q—Kt4
2	P—KB4	P×P	14	Q—B3	Kt—Kt1 (*c*)
3	B—B4	P—QKt4	15	B×P	Q—B3
4	B×KtP	Q—R5ch	16	Kt—B3	B—B4 (*d*)
5	K—B1	Kt—KB3	17	Kt—Q5	Q×P (*e*)
6	Kt—KB3	Q—R3	18	B—Q6 (*f*)	B×R
7	P—Q3	Kt—R4 (*a*)	19	P—K5	Q×Rch
8	Kt—R4	P—QB3	20	K—K2	Kt—QR3 (*g*)
9	Kt—B5	Q—Kt4	21	Kt×Pch	K—Q1
10	P—KKt4	Kt—B3	22	Q—B6ch	Kt×Q
11	R—Kt1 (*b*)	P×B	23	B—K7 mate	
12	P—KR4	Q—Kt3			

(*a*) Threatening Kt—Kt6ch. But this lighthorse attack is backed by insufficient means. Black should have made a developing move, as B—Kt2 or even B—R3. (*b*) Commencing a combination based on the precarious position of the Black queen. (*c*) The only move to save the queen. (*d*) Perhaps better was B—Kt2 to keep out the terrible knight. But there is no move to parry all of White's threats. (*e*) Staying on the diagonal to defend KKt2. (*f*) The key move of the combination. Now if 18 . . . Q×Rch; 19 K—K2, Q×R then 20 Kt×Pch, K—Q1; 21 B—B7 mate. Or if 18 . . . B×B; 19 Kt×Bch, K—Q1 then 20 Q×P and mate cannot be averted. (*g*) To prevent the mate given in note (*f*).

Illustrative Game No. 2.—When Paul Morphy went to Europe in 1858 he met some unpleasant experiences with European masters jealous of their laurels. But Anderssen came out of retirement to play and lose a match to him in 1859, and he was generous in praise of the American genius. The present game was the seventh of the match.

	White Morphy	Black Anderssen		White Morphy	Black Anderssen
1	P—K4	P—Q4	14	Q×Kt	Q×B
2	P×P	Q×P	15	B—Q3 (*f*)	B—Kt5
3	Kt—QB3	Q—QR4	16	Kt—Kt5 (*g*)	KR—Q1
4	P—Q4	P—K4	17	Q—Kt4 (*h*)	B—B1
5	P×P	Q×Pch	18	KR—K1	P—QR4
6	B—K2	B—QKt5	19	Q—K7	Q×Q
7	Kt—B3 (*a*)	B×Ktch	20	R×Q (*i*)	Kt—Q4
8	P×B	Q×Pch	21	B×Pch	K—R1 (*j*)
9	B—Q2	Q—B4 (*b*)	22	R×KBP	Kt—B6
10	R—QKt1 (*c*)	Kt—QB3	23	R—K1	Kt×P
11	Castles	Kt—B3	24	R—B4	R—R3
12	B—KB4	Castles (*d*)	25	B—Q3	Resigns
13	B×P (*e*)	Kt—Q5			

(*a*) He could save the pawn and also develop by B—Q2, but he is perfectly willing to let Black waste further time to win it. (*b*) Black has won a pawn but lost the game. (*c*) Threatening B—Kt4 and also holding back the Black QB. (*d*) Giving back the pawn in

order to get his king to safety. If 12 . . . Kt—Q4 then 13 R—Kt5 wins a piece. (*e*) More than regaining his pawn, for now he threatens B—Q6. (*f*) White's advantage is greater than it may seem. He has the "good" bishop for a king's-side attack, while Black's "bad" bishop cannot even be moved out to release the QR. Black indeed tries to develop it, but the effort is quickly refuted. (*g*) Threatening 17 Kt×RP, Kt×Kt; 18 Q×B. (*h*) Maintaining the threat and also forking the QKtP. To avoid immediate loss of a pawn Black is forced to retreat his bishop. (*i*) The exchange of queens has brought Black no relief. Useless to defend the KBP is 20 . . . R—B1, for then 22 Kt×BP, R×Kt; 23 B—B4 wins the exchange. (*j*) Forced, for if K—B1 then 22 R×Pch, K—K1; 23 R—K1ch leads to mate.

Illustrative Game No. 3.—J. H. Zukertort (1842–88) was a brilliant combination player. He reached the zenith of his powers in the London tournament of 1883, which he won without loss of a single game, although the entry list included all the greatest masters of the day, including Steinitz.

London, 1883

	White Zukertort	Black Blackburne		White Zukertort	Black Blackburne
1	P—QB4	P—K3	17	QR—K1	R—B2
2	P—K3	Kt—KB3	18	P—K4	QR—QB1
3	Kt—KB3	P—QKt3	19	P—K5 (*b*)	Kt—K1
4	B—K2	B—Kt2	20	P—B4	P—Kt3
5	Castles	P—Q4	21	R—K3	P—B4(*c*)
6	P—Q4	B—Q3	22	P×P e.p.	Kt×P (*d*)
7	Kt—B3	Castles	23	P—B5 (*e*)	Kt—K5
8	P—QKt3	QKt—Q2	24	B×Kt (*f*)	P×B
9	B—Kt2	Q—K2	25	P×KtP	R—B7 (*g*)
10	Kt—QKt5	Kt—K5	26	P×Pch	K—R1
11	Kt×B	P×Kt	27	P—Q5ch	P—K4
12	Kt—Q2	QKt—B3	28	Q—Kt4! (*h*)	R(B1)—B4
13	P—B3	Kt×Kt	29	R—B8ch	K×P (*i*)
14	Q×Kt	P×P	30	Q×Pch	K—Kt2
15	B×P	P—Q4	31	B×Pch	K×R
16	B—Q3	KR—B1 (*a*)	32	B—Kt7ch (*j*)	Resigns

(*a*) The subsequent course of the game shows that Black should have taken immediate measures to counteract the advance of the White KP. (*b*) This game and many others have shown the danger of allowing the KKt, the strongest defensive piece on the king's side, to be driven away from B3 by a supported pawn. (*c*) Necessary sooner or later so that KR2 can be protected along the rank. (*d*) If Q×P to get out of the pin, then 23 Q—K1 and the backward KP must fall. (*e*) Initiating a magnificent combination. (*f*) The combination has to be exactly calculated, for this exchange opens the way for a powerful counterattack on the QB file. (*g*) Best. Too slow is P×P; *e.g.*, 26 R—Kt3, Q—Kt2; 27 P—Q5, P—K4; 28 Q—Kt5. (*h*) The first point of the combination. If Q×Q then 29 B×Pch, K×P; 30 R—R3ch, K—Kt3; 31 R—Kt3ch, K—R3; 32 R—B6ch, K—R4; 33 R—B5ch, K—R3; 34 B—B4ch, K—R2; 35 R—R5 mate. (*i*) The second point. If Q×R then 30 B×Pch, K×P; 31 Q×Pch leads to mate. (*j*) The third point. If Q×B, then Q—K8 mate. After any other move, the queen is lost.

Illustrative Game No. 4.—Steinitz had his revenge for being outdistanced by Zukertort in the London tournament of 1883, by beating him in a match in 1885. According to Lasker, this match was a battle of "positional play" against "combination play," and it had far-reaching consequences upon chess theory.

	White Steinitz	Black Zukertort		White Steinitz	Black Zukertort
1	P—K4	P—K4	18	Kt—Kt3	B—K3
2	Kt—KB3	Kt—QB3	19	R—K1	Kt—Kt2
3	B—Kt5	Kt—B3	20	P—KR4 (*e*)	Q—Q2
4	Castles	Kt×P	21	P—R5	B—B2
5	R—K1	Kt—Q3	22	P×P	B×P!
6	Kt×P	Kt×Kt	23	Q—K3	K—B2
7	R×Ktch	B—K2	24	Q—B4	R—K1

17	Q—Q4 (*d*)	P—B3			

(*a*) According to Steinitz, the king's-side pawns when under attack should not be moved unless there is no alternative. In his notes to this game he states that he considered this move a deliberate challenge to his theory. (*b*) Manifestly antipositional. The bishop is vitally needed at Kt2 to protect the "holes" in the pawn structure. (*c*) Nailing down the weakness of Black's KB3. (*d*) To force the following advance, which is a further weakening of the pawn wing. (*e*) An attacking move seen in many Steinitz games, made to "loosen up" the compromised pawns still further. (*f*) "From the 14th move until this moment Black, on the defense, has played good chess. Now White has no immediate threats and Black . . . is thrown on his own initiative . . . he has to originate a plan. But that is exactly what Zukertort did not understand . . . His right plan was to keep attention riveted on his weak points KB4, QB4 and KB3, and . . . work towards a draw by exchanging perilous pieces . . ."—Lasker.[1] (*g*) Actually Steinitz checked with the knight several times, to gain time, before making this move. (*h*) "All" that Steinitz has to show for his exertions is the win of a pawn. But this is enough to win the ending.

Illustrative Game No. 5.—Before completing his development, Steinitz moves his QKt three times, only to exchange it a few moves later. His games are full of such long-winded manoeuvres, in pursuit of modest but lasting positional advantages. Observe how carefully he refrains from P—Q4 until the move is decisive.

(*a*) At variance from the then-fashionable practice of playing P—Q4 as soon as possible. (*b*) This pawn formation was frequently adopted by Steinitz after 1 P—K4. Its object is only remotely to enforce P—Q4; the primary purpose is to neutralize any effort by Black to break the centre. (*c*) The king's fianchetto was formerly much played against the Ruy Lopez, but it has dropped out of master practice as a result of Steinitz' victories against it. (*d*) Another of Steinitz' innovations was this manoeuvre B—Kt5—R4—B2 to preserve the KB, "the thorn of the Ruy Lopez." (*e*) The virtue of this post is that it discourages 9 . . . P—B4, for after 10 P×P Black could not retake with the rook, and so keep the file open. (*f*) Again P—B4 would be premature; *e.g.*, 11 P×P, B×P; 12 Kt×B, R×Kt?; 13 P—Q4. (*g*) This typical Steinitz attack is the more powerful since he has delayed castling and still has his rook on the file. (*h*) "The logical reaction against a wing advance is a break in the centre." Black expects to profit from opening lines against his "undeveloped" opponent (*i*) But it is White who profits. To avoid the opening of the diagonal upon his king, Black might have tried 13 . . . RP×P but then would have had to reckon with an attack on the open KR file. (*j*) Meeting the immediate threat of Kt—B5. But the move also has a subtle attacking purpose. (*k*) This long-delayed advance is now devastating. Black can scarcely avoid the exchanges that follow, because of the awkward situation of his queen, knight and QB. (*l*) An unpleasant surprise. After 24 B×Ktch, R—B3 Black could still put up a defense

Illustrative Game No. 6.—Siegbert Tarrasch was a prolific writer as well as a master player. He made large contributions to the Steinitz theory of positional play. Here he gives a classic demonstration of what ills may follow "surrender of the centre."

[1] From Emanuel Lasker, *Lasker's Manual of Chess*, published by David McKay Co., Philadelphia.

(*a*) The defense favoured by Steinitz. (*b*) A precept of Tarrasch was to answer P—Q3 with P—Q4 (after 1 P—K4, P—K4). White thus attacks the Black KP; if Black plays P×P he "surrenders the centre" by leaving White a central pawn on the fourth rank, while Black's pawn is only on the third rank. (*c*) Prior to this move White could not win a pawn by B×Kt and P×P because his own KP would then be lost. But now he does threaten to win a pawn. This Tarrasch procedure against the Steinitz defense has caused it to be abandoned in master play. (*d*) Tarrasch emphasized that the player having the advantage of greater space should seek to avoid exchanges. If the bishop were developed at B4 or Kt5 it would soon have to be exchanged. (*e*) White threatened Kt—Q5. (*f*) Both to prevent Kt—Kt5 and to prepare the general advance of the king's-side pawns. (*g*) The paramount positional consideration is to prevent the liberating move P—Q4. (*h*) Still holding back the QP and preparing to swing the knight to the king's side. (*i*) It has been pointed out that Black could have played P—Q4 at this moment; *e.g.*, 24 KP×P, R×R; 25 R×R, R×R; 26 P×R, Q—Kt3. (*j*) Having parried Black's few threats, White is now ready to send the knight to KB5 and launch a decisive attack. Black's restriction in space prevents his getting the QR and KB into effective action. (*k*) If R×P then 35 Q—B3 is murderous.

Illustrative Game No. 7.—This game has been called the most important in history, for it exposed the inadequacy of the orthodox defense to the queen's gambit declined. Theorists have been occupied ever since with finding ways to circumvent the dread Pillsbury attack. Harry N. Pillsbury (1872–1906), U.S. champion, placed first at Hastings in a field that included Lasker, Steinitz, Tarrasch and Tchigorin.

25	Kt—B3	B—Q4	51	Q×Kt	P—B7 (*u*)
26	Kt—B2	Q—B3	52	Q×P mate	

(*a*) The key move of the Pillsbury attack. (*b*) Black's problem in the queen's-side openings is to find a way to get his QB into action This immediate fianchetto was standard procedure for many years, and was stoutly championed by Tarrasch, but the Pillsbury system has caused it to be abandoned. (*c*) So as to keep the diagonal closed. By this exchange White cedes his opponent a pawn majority on the queen's side. As pointed out by Steinitz, this majority is a positional advantage, for if all the heavy pieces are exchanged the ending is often won for the player who has a pawn majority on the side remote from the kings. White therefore must strive to win in the midgame. While Black advances on the queen's wing, he must attack on the king's side. The particular importance of this game is that it finally convinced players that White's attack gets home first. (*d*) Capturing with the knight would let White play P—K4 soon, with greater control of the centre. (*e*) a wasted move. Pillsbury subsequently improved the system by leaving the rook on KB1. (*f*) Except that the KR should be on KB1, White has now achieved the "set position" for which the Pillsbury system strives. (*g*) This knight must eventually be swung to the king's side to reinforce the attack. (*h*) Though condemned by some annotators, this move seems necessary sooner or later to block the White KBP. (*i*) White threatened Kt×P. (*j*) Now Black wastes a move, since the rook goes to K1 two moves later. (*k*) White is preparing to attack the isolated KP with four pieces, so that Black must bring four to the defense. (*l*) Here and later White's manoeuvres seem maddeningly slow. But Pillsbury had a genius for calculating exactly the time available for an attack. (*m*) At last the counterattack gets under way, and the race is on in earnest. (*n*) He must pause to defend the KBP, else Kt×P will win. (*o*) Again preventing Q×P, for then 31 Kt—B4, B—B2; 32 Kt—Kt6ch, B×Kt; 33 P×B is too strong; *e.g.*, 33 . . . P—R3; 34 R×P, Kt×R; 35 R×Kt, P×R; 36 Q×RPch, K—Kt1; 37 Kt×P mate. (*p*) Commencing another seemingly slow manoeuvre, the advance of the KKtP. (*q*) Now if Black can parry the attack on his king, his two passed pawns must win. White must also reckon with a counterattack on his second rank; *e.g.*, if 39 Kt×B?, R×Kt; 40 R—KKt2, R—Kt7! (*r*) His KBP was attacked more times than it was defended, because of the potential pin of the KKtP. (*s*) Forced, for if K—B1, then 45 Q—Kt8ch and 46 Q×R. (*t*) The slowest-looking move of all! Yet to avoid mate Black has no resource but to give up his queen and knight. (*u*) Probably not an oversight, but desperation, hoping for 52 Q—K6ch and 53 Q×R, after which 53 . . . P queens ch might actually win.

Illustrative Game No. 8.—The importance of maintaining sufficient space to manoeuvre is discussed by A. Nimzowitsch in his book *Die Blockade*. He won several notable games by strangling the entire adverse army.

Copenhagen, 1923

	White Sämisch	Black Nimzowitsch		White Sämisch	Black Nimzowitsch

12	Q—Kt3	Kt—B3	25	QR—K1	P—R3 (*k*)
13	Kt×Kt	B×Kt		Resigns	

(*a*) The opening is all "book" so far. The natural move P—B4 has been shown to be somewhat hazardous. The object of P—B3 is to relieve the uncomfortable pin on the QB. Also played in this position is Q—B1. (*b*) In order to leave the Black QB locked behind its own centre pawns. (*c*) This post for the bishop is always dubious after its retreat to Kt3 has been blocked by the pawn advance. (*d*) The method of restraining the Black queen's-side pawns here attempted by White is shown to be futile. Necessary was the mechanical blockade, P—QR3 and P—QKt4. (*e*) White is laboriously preparing a pawn advance, but the misplaced bishop allows Black to strike first. (*f*) Threatening after due preparation to move P—B5 and smash the compromised king position. White's unmoved KP is an obstacle to bringing the queen's-side pieces over to the defense, hence White's ensuing plan to advance it. (*g*) Exacting heavy toll for White's failure to block the pawn, and his omission of moving the KP. The knight is forced back home, where it remains stalemated for the rest of the game. (*h*) At last White threatens to move P—K4, discovering attack on the knight by the queen. Black, having already won great superiority in space, ignores the threat. (*i*) "Two pawns, and a rook on the seventh rank, all for one knight!" remarks Nimzowitsch. (*j*) Shutting off access to the haven QKt3 and threatening R—K7. (*k*) "Announcing the *zugzwang*." White has no moves left; *e.g.*, 26 B—QB1, B×Kt, or 26 K—R2, QR—B6, or 22 QR moves, R—K7. After exhausting his pawn moves, White will be forced to move a piece and commence losing material.

Illustrative Game No. 9.—At move 8, Réti illustrates "the golden rule is that there is no golden rule" by switching from a "hypermodern" formation to a "classical."

New York city, 1924

	White Réti	Black Bogoljubow		White Réti	Black Bogoljubow
1	Kt—KB3	Kt—KB3	14	Kt×Kt	B×Kt
2	P—B4 (*a*)	P—K3	15	P—K4	P—K4 (*k*)
3	P—KKt3	P—Q4	16	P—B5	B—KB1
4	B—Kt2	B—Q3	17	Q—B2 (*i*)	P×QP
5	Castles	Castles	18	P×P	QR—Q1 (*j*)
6	P—Kt3	R—K1	19	B—R5 (*k*)	R—K4
7	B—Kt2	QKt—Q2	20	B×P	R×P
8	P—Q4 (*b*)	P—B3 (*c*)	21	R×R	B×R
9	QKt—Q2	Kt—K5 (*d*)	22	Q×B	R×B
10	Kt×Kt	P×Kt	23	R—KB1	Q—Q1 (*l*)
11	Kt—K5	P—KB4	24	B—B7ch	K—R1
12	P—B3 (*e*)	P×P	25	B—K8!	Resigns (*m*)
13	B×P (*f*)	Q—B2 (*g*)			

(*a*) The opening moves of the so-called Réti system. (*b*) One idea of the system is to avoid blocking the diagonal of the QB, making the break in the centre by P—Q3 and P—K4. But Réti perceives that reversion to the "normal position" of the queen's gambit declined is strongest against the formation adopted by Black. (*c*) Forced in order to retreat B—B2 in case White plays P—B5. This advance is powerful when Black cannot counter with P—K4. If the bishop were forced to retreat to B1, White would have time for P—QKt4 and

Kt—K5, with strangling effect. (d) Subsequent analysis indicates P—K4 to be Black's best move, but it is insufficient to overcome White's positional superiority. (e) White forces open the centre to capitalize the superior position of his pieces. (f) Of course not P×P, as the KP is to be used as a battering-ram. (g) One of Black's problems is to develop his QB. This move certainly seems to have better prospects than 13 . . . Kt×Kt; 14 P×Kt, B—B4ch; 15 K—Kt2, because White would then gain command of the open Q-file. (h) He must not allow P—K5, and P×P would leave his KP isolated. "Black appears to have surmounted the greater part of his early difficulty and it calls for exceptionally fine play on the part of White to make the hidden advantages of his position count so rapidly and convincingly."—Alekhine.[1] (i) Guarding his QB5 to threaten P×QP, and also threatening P×KBP. If Black now plays P×KP, then B×P and White wins either the KP or the KRP. (j) Indirectly guarding the QP; e.g., 19 B×QP, B×KBP. (k) Initiating a beautiful combination that won this game the first brilliancy prize. (l) No better is 23 . . . Q—K2; 24 B—B7ch, K—R1; 25 B—Q5, Q—B3; 26 Q—B8. (m) To avert mate he must give up at least the bishop.

Illustrative Game No. 10.—This game was hailed as an example of the "hypermodern" style. Alekhine, however, vehemently repudiated the allegation.

(a) Black is reluctant to lose a tempo by 5 . . . Kt×P; 6 P—K4 or 5 . . . Q×P; 6 Kt—QB3. But the weak move chosen is at once shown by White to be a much more serious loss of time. (b) Giving up the KP to save the QP. The merit of this transaction is that the pawn at Q5 exerts a terrible cramp on the Black development. While the QP looks difficult to maintain in the long run, White actually succeeds in promoting it! (c) With the object of forcing Black to mask his own attack on the QP. Black cannot reply P—QKt4 because of 8 Kt×P, nor Q—Q2 because of 8 B—QKt5. If Kt—Q2, then 8 Kt—K6, P×Kt; 9 P×P would be unpleasant. (d) Black is kept busy meeting short threats. Now he has to defend the QKtP. (e) Holding back the KP; e.g., 9 . . . P—K3?; 10 P—QKt4, Kt—R5; 11 P×P, etc. Black therefore decides to fianchetto his KB. (f) "This gain of time allows White to prevent 10—B—Kt2 followed by castling. Black's king being kept in the center, White's attack will be facilitated, thanks to his superior development . . . The advantage won results from repeated movements of the same pieces (here the first eleven moves contain four displacements of the queen and three of the king's knight). But the possibility of like maneuvers in the opening phase is *solely* attributable, I must reiterate, to the fact that the opponent has adopted faulty tactics, which must from the first be refuted by an energetic demonstration. It is clear, on the contrary, that in the face of correct development, similar anomalous treatment would be disastrous. It cannot therefore be any question of a 'Modern System', but just simply of exploiting in a rational manner the opponent's mistakes."—Alekhine.[2] (g) He cannot even play P—B3 in order to save the right to castle, for White also threatens P—QKt4 winning the knight. After the text move Black could answer P—QKt4 with B—Kt2. (h) Now observe the wretched state of Black's game! His king is held in the centre, his pawns are disorganized and the QP still hampers his development. (i) Against passive defense White plays R—K3 and R—KB3.

Illustrative Game No. 11.—The fear that chess is becoming exhausted is continually given the lie by the revival of old variations once thought to have been refuted. A galaxy of Russian chess stars has taken the lead in re-examining "the book."

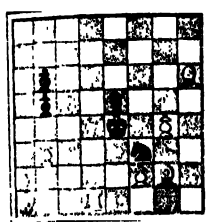
(a) The first 18 moves are identical with a game Duras-Maróczy, Ostend, 1906. After the sacrifice of the knight, Maróczy won, and the game was taken to indicate that 16 P—B3 by White is unsound. But in the Moscow championship tournament of 1942, Boleslavsky played it against Ragozin, captured the knight and won. The Russian analysts got busy and established to their satisfaction that the variation is playable for White. Smyslov was acquainted with this analysis, taking only eight minutes for his first 25 moves, while Reshevsky, who had not studied it, was consuming an hour and a half. (b) This is the improvement over Duras' play. White gets value for his queen in pieces, but it is not easy to see how he can withstand the advance of the Black queen's-side pawns. (c) By this threat of mate Black wins both White centre pawns, gaining himself a formidable supported passed pawn. (d) One point of the analysis is that Black cannot attack the bishop by P—KKt4, P—KR4 and P—KKt5. After playing BP×KtP White can move R—KB4 and the attack is smashed. (e) White now threatens 32 R×R, Q×R; 33 R—Q1, which previously could have been answered by Q—R3, check. (f) The effort to maintain the *status quo* by R—K7 would come to naught, as White would now be willing to play R×Q, for after the exchanges the Black rook would not attack the White KBP. (g) The White manoeuvres have cleared the Q-file for his rook, and now his superior forces institute an irresistible mating attack.

CHESS PROBLEMS

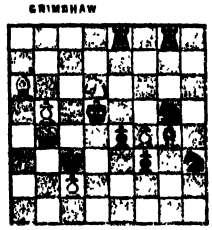
Chess problems are artificial positions, constructed to show dynamic possibilities of the pieces. Each is accompanied by a stipulation, as "(White to) mate in two moves." In the beginning, no doubt, problems were posed as mere puzzles, the sole interest being to discover the solution. But even from early times problem composers have been as much occupied with exploring strategic ideas as with baffling the solver. Today the chess problem is recognized as an aesthetic form, cast by accident of history in the form of a puzzle.

NO. 1.—MATE IN FIVE NO. 2.—MATE IN TWO NO. 3.—MATE IN TWO



The first problems of which we have record were Arabian *mansubat* (betting problems). The earliest known manuscript was a collection by al-Adli, about A.D. 840; it was lost, but much of its contents was preserved in later collections. Chief of these is the compilation made by one who signed himself "Bonus Socius."

The National library at Florence contains a copy of the Bonus Socius manuscript, with 149 problems, believed to date from the late 13th century (1266?). Some of the problems no doubt were recorded from actual play, such as No. 1 (1 Sc3; 2 Se4; 3 Sd2; 4 Sf1; 5 Sg3). But there are many evidences of constructive editing, by deletion of superfluous pieces, and there are



also outright inventions, such as No. 2 (1 Rh7—g7).

What is called the modern period began about 1840, in the compositions of an Englishman, Rev. Horatio Bolton (1793–1873); a Belgian, August d'Orville (1813–?); and the German master player Adolph Anderssen (1818–79). The beauty of "quiet" keys first began to be explored, as in No. 3 (1 Rd5). A great revival of interest culminated in the publication of a compilation of 2,000 problems, by A. Alexandre, at Paris, 1846. In 1845 was published the problem destined to become the most famous in history, the "Indian problem," No. 4 (1 Bc1; 2 Kb1 or other waiting move; 3 Rd2, Kf4; 4 Rd4 doublecheck mate). It was quoted in chess periodicals all over the world and stimulated intensive exploration of the strategy peculiar to problems. In the period 1845–61 were discovered many of the basic themes, as "Grimshaw induced interference," No. 5 (1 Bc8, B×B; 2 Qf6, Re6; 3 Qd4ch, K×Q; Sf5ch); "Novotny interference by obstruction," No. 6 (1 Sg3, Re8; 2 Rb2—c2, B×R; 3 Sf2—e4); and "Bristol clearance," No. 7 (1 Rh1, Bd7; 2 Qb1; 3 Qg1).

No. 6.—MATE IN FOUR

The later 19th century saw the emergence of several national schools with divergent ideals. The German school, including Philip Klett (1833–1910), Conrad Bayer of Austria (1828–97), Johann Berger (1845–1933; author of *Das Schachproblem*), J. Kohtz and C. Kockelkorn (authors of *Das Indische Problem*, 1903), emphasized strategy.

The Bohemian school, including J. Pospisil (1861–1916, author of *Ceske Ulohy Sachove*, 1888), Jan Dobrusky (1853–1907), G. Chocholous (1856–1930), M. Havel (1881–), emphasized "echoes"—reproduction of the same mating net in different orientations.

The English school, including B. G. Laws (1861–1932; author of *The Chess Problem Textbook*, 1886), C. Planck (1856–1935), A. F. Mackenzie (1861–1905; the blind composer of Jamaica), Godfrey Heathcote (1870–), emphasized economy and accuracy, especially as embodied in "model mates." (*See* No. 8 [1 Sd6, B×S; 2 Qe2, Bf4; 3 P×B]; No. 9 [1 Qe3, P×B; 2 Qb3ch, K×S; 3 Rc2. Or 1 . . . K×B; 2 Rc2, P×S; 3 Rd2]; No. 10 [1 Sa2, P×S; 2 Qc2. Or 1 . . . Kd2; 2 Kf3. Or 1 . . . Kd4; 2 Bf2ch. Or 1 . . . Ke2; 2 Sb4].)

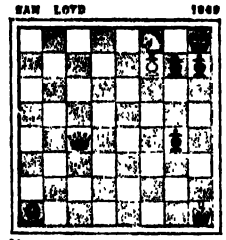
No. 9.—MATE IN THREE

The American school has been called cosmopolitan. Sam Loyd (1841–1911) was a master of the surprise move, but also pioneered in the discovery of many themes. (*See* No. 11 [1 Qf1, Bb2; 2 Qb1. Or 1 . . . Bc3 or d4; 2 Qd3. Or 1 . . . Be5 or f6; 2 Qf5. Or 1 . . . Pg3; 2 Sg6ch].)

The same wide range of interest and facility in many styles was displayed by W. A. Shinkman (1847–1933) and Otto Wurzburg (1875–).



National distinctions have tended to evaporate in the world-wide exchange of problem ideas. In the period 1913–24, the Good Companion club of Philadelphia, an international association of composers founded by J. F. Magee, Jr. (1867–), gave great impetus to the study of direct mates in two moves. Many new ideas were discovered by such men as G. Guidelli of Italy (1897–1924), A. Ellerman of Argentina (1893–), C. Mansfield of England (1896–), J. Schiffmann of Austria. More recently, new paths have been blazed by composers of the U.S.S.R., such as M. M. Barulin, A. P. Gulyaev and L. I. Kubbel. (*See* No. 12 [1 Be4]; No. 13 [1 Qf3]; No. 14 [1 S×P].)

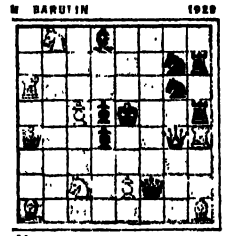
No. 12.—MATE IN TWO



A direct mate is a problem in which White is required to mate Black against his resistance. Many "unorthodox" forms have also been devised. In a selfmate, White must force Black to checkmate the White king, while Black seeks to avoid doing so. (*See* No. 15 [1 Rf2, K×R; 2 Qe2ch; 3 Qg2ch. Or 1 . . . Bg1; 2 Qg8ch; 3 Qg2ch].) In a helpmate, both sides conspire to mate one king, the difficulty being solely to weave a mating net. Other forms are the stalemate, maximate, reflex mate, and conditional mate. The properties of pieces with special powers have been investigated, such as the combination of a knight with queen, rook or bishop, under fanciful names, as chancellor, duke, templar, wazir, knight-rider, camel, giraffe, grasshopper. A pioneer in this field, called "fairy chess," was T. R. Dawson (1889–1952) of England.

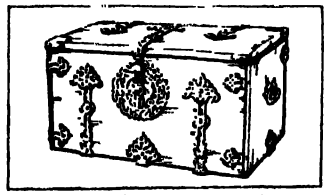
Modern interest in composition and solving is not confined to the difficulty, beauty and strategy of individual problems, but embraces the study of whole groups of problems and the classification of their themes. There exist large classified collections, such as that in the custody of C. S. Kipping of England (1891–), containing more than 150,000 examples. This collection was begun by Alain White of the United States, a composer and writer who has edited more than 40 compilations of problems in book form.



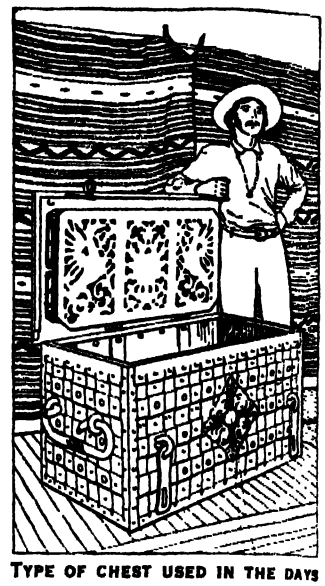
BIBLIOGRAPHY.—*Methods of Composition and Solution:* P. H. Williams, *The Modern Chess Problem* (1912); B. G. Laws, *Chess Problems and How to Solve Them* (1923); K. S. Howard, *The Enjoyment of Chess Problems* (1943). *History, Classification of Themes:* Alain White, *Simple Two-Move Themes* (1924); George Hume and Alain White, *The Good Companion Two-Mover* (1922); H. Weenink, *The Chess Problem* (1926). *Collections:* Alain White, the *Christmas Series* (more than 30 titles), *Sam Loyd and His Chess Problems* (1913), *A Sketchbook of American Chess Problematists* (1942) and *A Century of Two-Movers* (1941); Albrecht Buschke and others, *The Two-Move Chess Problem in the Soviet Union, 1923–1943* (1943); Frank Healey, *200 Chess Problems* (1908); F. Dedrle, *Echo* (1927). (G. MH.)

CHEST, a large box of wood or metal with a hinged lid. The term is used for many kinds of receptacles; and in anatomy indicates the portion of the body covered by the ribs and breastbone (*see* RESPIRATORY SYSTEM, ANATOMY OF). Chests as articles of furniture are of the greatest antiquity. The chest was the common receptacle for clothes and valuables, and was the direct ancestor of the "chest of drawers," which was formed by enlarging the chest and cutting up the front. It was also frequently used as a seat. Indeed, in its origin it took in great measure the place of the chair, which, although familiar enough to the ancients, was

a luxury in the days when the chest was already an almost universal possession. In the early middle ages the rich possessed them in profusion, used them as portmanteaux, and carried them about from castle to castle. These portable receptacles were often covered with leather and emblazoned with heraldic designs. As houses gradually became more amply furnished, chests and beds and other movables were allowed to remain stationary; and the chest finally took the shape in which we best know it—that of an oblong box standing upon raised feet. As a rule it was made of oak, but sometimes of chestnut or other hard wood.

Types.—There are, properly speaking, three types of chest—the domestic, the ecclesiastical and the strong box or coffer. Old domestic chests still exist in great number and some variety, but the proportion of those earlier than the latter part of the Tudor period is very small; most of them are Jacobean in date. Very frequently they were made to contain the store of house-linen which a bride took to her husband upon her marriage. In the 17th century Boulle and his imitators glorified the marriage-coffer until it became a gorgeous casket, almost indeed a sarcophagus, inlaid with ivory and ebony and precious woods, and enriched with ormolu, supported upon a stand of equal magnificence. The Italian marriage-chests (*cassone, q.v.*) were also of a richness which was never attempted in England. The main characteristics of English domestic chests (which not infrequently are carved with names and dates) are panelled fronts and ends, the feet being formed from prolongations of the "stiles" or side posts. A certain number of 17th-century chests, however, have separate feet, either circular or shaped after the indications of a somewhat later style.

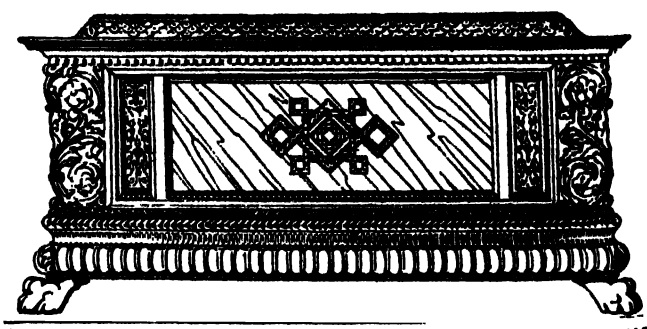
There is usually a strong architectural feeling about the chest, the front being divided into panels, which are plain in the more ordinary examples, and richly carved in the choicer ones. The plinth and frieze are often of well-defined *guilloche* work, or are carved with arabesques or conventionalized flowers. Architectural detail, especially the detail of wainscoting, has indeed been followed with considerable fidelity, many of the earlier chests being carved in the linenfold pattern, while the Jacobean examples are often mere reproductions of the pilastered and recessed oaken mantlepieces of the period.



BY COURTESY OF THE VICTORIA AND ALBERT MUSEUM

A SPANISH TREASURE CHEST OF THE 17TH CENTURY

Occasionally a chest is seen which is inlaid with coloured woods, or with geometrical parquetry. Perhaps the most elaborate type of English parquetry chest is that named after the vanished Palace of Nonesuch. Such pieces are, however, rarely met with. The entire front of this type is covered with a representation of the palace in coloured woods. Another class of chest is incised, sometimes rather roughly, but often with considerable geometrical skill.



The more ordinary variety has been of great value to the forger of antique furniture, who has used its carved panels for conversion into cupboards and other pieces, the history of which is not easily unravelled by the amateur who collects old oak. Towards the end of the 17th century chests were often made of walnut, or even of exotic woods such as cedar and cypress, and were sometimes clamped with large and ornamental brass bands and hinges. The chests of the 18th century were much larger than those of the preceding period, and as often as not were furnished with two drawers at the bottom—an arrangement but rarely seen in those of the 17th century—while they were often fitted with a small internal box fixed across one end for ready access to small articles. The chest was not infrequently unpanelled and unornamented, and in the latter period of its history this became the ruling type.

Ecclesiastical Chests.—These appear to have been used almost entirely as receptacles for vestments and church plate, and those which survive are still often employed for the preservation of parish documents. A considerable variety of these interesting and often exceedingly elaborate chests are still left in English churches. They are usually of considerable size, and of a length disproportionate to their depth. This no doubt was to facilitate the storage of vestments. Most of them are of great antiquity. Many go back to the 14th century, and here and there they are even earlier, as in the case of the coffer in Stoke d'Abernon church, Surrey, which is unquestionably 13th-century work. One of the most remarkable of these early examples is in Newport church, Essex. It is one of the extremely rare painted coffers of the 13th century, the front carved with an upper row of shields, from which the heraldic painting has disappeared, and a lower row of roundels. Between is a belt of open tracery, probably of pewter, and the inside of the lid is decorated with oil paintings representing the Crucifixion, the Virgin Mary, St. Peter, St. John and St. Paul. The well-known "jewel chest" in St. Mary's, Oxford, is one of the earliest examples of 14th century work. Many of these ecclesiastical chests are carved with architectural motives—traceried windows most frequently, but occasionally with the linenfold pattern. There is a whole class of chests known as "tilting coffers," carved with representations of tournaments or feats of arms, and sometimes with a grotesque admixture of chivalric figures and mythical monsters. Only five or six examples of this type are known still to exist in England, and two of them are now in the Victoria and Albert museum, London. It is not certain that even these few are of English origin—indeed, very many of the chests and coffers of the 16th and 17th centuries are of foreign make. They were imported into England chiefly from Flanders, and were subsequently carved by native artisans, as was the case with other common pieces of furniture of those periods. The *huche* or "hutch" was a rough type of household chest.

TYPE OF CHEST USED IN THE DAYS OF THE STAGE COACH FOR TRANSPORTING VALUABLES ACROSS THE AMERICAN PRAIRIES

Coffer is the word properly applied to a chest which was intended for the safe keeping of valuables. As a rule the coffer is much more massive in construction than the domestic chest; it is clamped by iron bands, sometimes contains secret receptacles opening with a concealed spring, and is often furnished with an elaborate and complex lock, which occupies the whole of the underside of the lid. Pieces of this type are sometimes described as Spanish chests, from the belief that they were taken from ships belonging to the Armada. However, these strong boxes are frequently of English origin, although the mechanism of the locks may have been due to the subtle skill of foreign locksmiths. A typical example of the treasure chest is that which belonged to Sir Thomas Bodley, and is preserved in the Bodleian

VENETIAN CHEST OF THE 16TH CENTURY, IN THE MUSEO NAZIONALE OF FLORENCE, ITALY

library at Oxford. The locks of this description of chest are of steel and are sometimes richly damascened.

Another kind of chest in use in earlier days was that signified in the expression a "chest of viols." This took the form of a solidly constructed, baize-lined press or cupboard, designed to accommodate stringed musical instruments—in the case of a "chest of viols," six viols of varying sizes.

CHESTER, EARLS OF. The important palatine earldom of Chester was first held by a Fleming named Gherbod (fl. 1070), and then from 1071 by Hugh of Avranches (d. 1101), a son of Richard, viscount of Avranches. As the friend of St. Anselm, Hugh showed the customary liberality to religious houses. His life was spent in fighting in Wales and Normandy, and he died on July 27, 1101. Hugh's only son Richard, who was childless, was drowned in the "White Ship" in Nov. 1120. Among subsequent holders were Ralph, or Randulph, de Gernon (d. 1153), prominent in the civil wars under Stephen, fighting first on one side and then on the other; and his son Hugh de Kevelioc (1147–81), who shared in the rising against Henry II in 1173. The most celebrated of the earls was Ralph, Ranulf or Randulph, de Blundevill (*c.* 1172–1232), who succeeded his father Hugh de Kevelioc in 1181 and was created earl of Lincoln in 1217. He married Constance, widow of Henry II's son, Geoffrey of Brittany, and is sometimes called duke of Brittany and earl of Richmond. He fought in Wales, sided with John against the barons and fought for Henry III against the French invaders and their allies. In 1218 he went on crusade to the Holy Land and took part in the capture of Damietta. He died at Wallingford in Oct. 1232. Stubbs calls him "almost the last relic of the great feudal aristocracy of the Conquest."

In the *Vision of Piers Plowman* Ranulf's name is linked with that of Robin Hood. Ranulf being childless, in Nov. 1232 the earldom was granted to his nephew John the Scot, earl of Huntingdon (*c.* 1207–1237). In 1246 it was annexed to the English crown.

In 1254 Prince Edward, afterward Edward I, was created earl of Chester, and from that time the earldom always held by the heirs apparent to the English crown. From 1399 the earls of Chester were also princes of Wales, although the act of Richard II (1398), which created Chester into a principality to be held by the king's eldest son, was revoked by Henry IV.

CHESTER, county borough, city, seaport and the county town of Cheshire, Eng., 16 mi. S. of Liverpool. Pop. (1951) 48,237. Area, 6.5 sq.mi. It lies in a low plain on the Dee, principally on the north (right) bank, 6 mi. above the point at which the river opens out into its wide shallow estuary. It is an important railway centre.

History.—The Roman station of Deva was founded about A.D. 48 by Ostorius Scapula, and from its key position in relation both to the north Wales coastal route and to the northward avenue past the Mersey, it became an important military and commercial centre. In A.D. 78–79 it was the winter quarters of Agricola, and later became the permanent headquarters of the 20th legion, Valeria Victrix. Many inscriptions and remains of the Roman military occupation have been found, and the north and east walls stand in great part on Roman foundations. The Saxon form of the name was Leganceaster. About 614 the city was destroyed by Aethelfrith, and lay in ruins until 907, when Aethelflaed rebuilt the walls and restored the monastery of St. Werburgh. In the reign of Aethelstan there was a mint at Chester, and in 973 it was the scene of Edgar's triumph when, it is said, he was rowed on the Dee by six subject kings. It resisted the Conqueror, and did not finally surrender until 1070. On the erection of Cheshire into a county palatine after the Conquest, Chester became the seat of government of the palatine earls. The Domesday account of the city includes a description of the Saxon laws under which it had been governed in the time of Edward the Confessor. All the land, except the bishop's borough, was held of the earl, and assessed at 50 hides.

The earliest extant charter, granted by Henry II in 1160, empowered the burgesses to trade with Durham as freely as they had done in the reign of Henry I. From this date a large collection of charters enumerates privileges granted by successive earls and later sovereigns. Three from John protected the trade with Ireland. Edward I granted the citizens the fee farm of the city at a yearly rent of £100. In the 14th century Chester began to lose its standing as a port through the gradual silting up of the Dee estuary, and the city was further impoverished by the inroads of the Welsh. Continued misfortunes led to reductions of fee farm by Richard II and by Henry VI, who also made a grant for the completion of a new Dee bridge, the old one having been swept away by an unusually high tide. Henry VII reduced the fee farm to £20, and in 1506 granted "the Great Charter," which constituted the city a county by itself and incorporated the governing body under the style of a mayor, 24 aldermen and 40 common councilmen. This charter was confirmed by James I and Charles II. The charter of Hugh le Gros to the abbey of St. Werburgh includes a grant of the tolls of the fair at the feast of St. Werburgh for three days, and a subsequent charter from Ranulf de Blundevill (12th century) licensed the abbot and monks to hold their fairs and markets before the abbey gates. Friction between the abbot and civic authorities lasted until, in the reign of Henry VIII, it was decreed that the right of holding fairs was vested exclusively in the citizens. Charles II in 1685 granted a cattle fair to be held on the first Thursday in February. The city is divided into four principal blocks by the four principal streets—Northgate street, Eastgate street, Bridge street and Watergate street, which radiate at right angles from the cross and terminate in the four gates. These four streets exhibit in what are called "the rows" a characteristic feature of the city. In Eastgate street, Bridge street and Watergate street, the rows exist on each side of the street and form continuous galleries open to the street, from which they are approached by flights of steps. The rows are flagged or boarded under foot and ceiled above, thus forming a covered way, standing in the same relation to the shops, which are at their back, as the foot pavement does in other towns. On the west side of Northgate street, on the other hand, the row is formed out of the ground floor of the houses, having cellars beneath. The rows and the old half-timbered houses combine to give the city a picturesque and individual character. Among the ancient houses are Derby house, bearing the date 1591, Bishop Lloyd's house and God's Providence house in Watergate street and the Bear and Billet in Lower Bridge street; the last three date from the 17th century. A mortuary chapel of the early part of the 13th century exists in the basement of a house in Bridge street.

Chester is the only city in England that still possesses its walls perfect in their entire circuit of 2 mi. The gateways were all rebuilt at various dates: the north and east gates on the site of the Roman gates. The Grosvenor bridge (1832), a single span of stone 200 ft. in length, one of the largest in Europe, carries the road to Wrexham and Shrewsbury over the Dee on the southwest; while there is also an old bridge of seven arches. The castle, with the exception of Caesar's tower and a round tower with adjacent buildings, was taken down about 1790 and replaced by a barracks, county hall, jail and assize courts.

The cathedral church of Christ and the Virgin Mary stands toward the north of the city within the walls on an ancient site. In 1093 Hugh le Gros, earl of Chester, richly endowed the original foundation as a Benedictine monastery. The bishops of Mercia had apparently a seat at Chester, but the city had ceased to be episcopal until in 1075 Peter, bishop of Lichfield, removed his seat thence to Chester, having for his cathedral the collegiate church of St. John (*see* below). The see, however, was moved again to Coventry (1102), but Cheshire continued subject to Lichfield until in 1541 Chester was erected into a bishopric by Henry VIII, the church of the dissolved abbey of St. Werburgh becoming the cathedral. The diocese covers nearly all Cheshire, with small portions of Flintshire, Lancashire and Staffordshire. The cathedral, while not of first rank architecturally, gains in beauty from the tones of its red sandstone walls and from its picturesque close. It is cruciform with a central tower 127 ft. high. The nave is short (145 ft.), being of six bays; the southern arcade is Decorated, while the northern differs in detail. The basement of the northwestern tower is Norman and formed part

of Hugh "Le Gros's" church. The north transept also retains Norman work, and its size shows the original plan, limited by the existence of the conventual buildings to the north. The south transept has aisles, with Decorated and Perpendicular windows. The fine organ stands on a screen across the north transept. The choir is a fine example of transitional Early English Decorated enhanced by the ancient carved wooden stalls unsurpassed in England. The Lady Chapel, east of the choir, is of rich Early English workmanship. Of the conventual buildings the cloisters are Perpendicular. The chapter-house, entered by a beautiful vestibule from the east cloister, is Early English (*c.* 1240). The refectory, adjoining the north cloister, is of the same period, with Perpendicular insertions; it retains its beautiful Early English lector's pulpit. An early Norman chamber, with massive pillars and vaulting, adjoins the west cloister, and may be the substructure of the abbot's house. The domestic buildings have been completely restored, the work being finished in 1928. The abbey gateway is of the 14th century. Within the walls there are several churches of ancient foundation: St. Peter's is said to occupy the site of a church erected by Aethelflaed, queen of Mercia, and St. Mary's dates from the 12th century. The church of St. John, outside the walls, which became the cathedral in 1075, is a massive early Norman structure, with later additions and restorations. It was a collegiate church until 1547. The Grosvenor Museum and School of Art, the foundation of which was suggested by Charles Kingsley the novelist, when canon of Chester cathedral, contains local antiquities and a fine collection of the fauna of Cheshire. The King's school, founded by Henry VIII (1541), was reorganized on the lines of a public school in 1873. Other educational institutions include the diocesan training college. Roodee, a level tract by the river at the base of the city wall, is appropriated as a race-course. An annual race-meeting is held in May. The town gains in prosperity from its large number of tourists. Manufactures are shot, white lead and paint, and tobacco and snuff. There is some shipping on the Dee but the river is principally used for pleasure vessels and rowing. The city of Chester parliamentary division, returning one member, includes the rural district of Chester and the urban district of Hoole. From 1553 Chester returned two members until 1885, when the representation was reduced to one member. The trades of tanners, skinners and glove-makers existed at the time of the Conquest, and the importation of marten skins is mentioned in Domesday. In the 14th century the woollen trade was considerable, and in 1674 weavers and wool-combers were introduced into Chester from Norwich. The restoration of the channel of the Dee opened up a flourishing trade in Irish linen, which in 1786 was at its height, but from that date gradually diminished.

See *Victoria County History, Cheshire;* R. H. Morris, *Chester in the Plantagenet and Tudor Reigns* (Chester, 1894); Joseph Hemingway, *History of the City of Chester* (2 vols., Chester, 1831).

CHESTER, a city of Delaware county, Pa., U.S., on the Delaware river, 13 mi. S.W. of Philadelphia. It is on U.S. highways 13 and 322, and is served by the Baltimore and Ohio, the Pennsylvania and the Reading railroads. The population in 1950 was 66,039 and was 59,285 in 1940 by the federal census. Chester has a good harbour, with considerable commerce. It is in an intensively industrialized area, with enormous shipbuilding plants, steel mills, automotive and locomotive works. Other manufactures of importance are cotton, silk and woollen goods, paper, iron, lace, hosiery and steel tubing. At the city of Chester is the Pennsylvania Military college, the second oldest military college in the United States. On the edge of the city is Crozer Theological seminary (Baptist), founded in 1867 by the family of John P. Crozer (1793–1866). Settled about 1645 by the Swedes and Finns, who called it Uplandt, Chester is the oldest town in Pennsylvania. It was the seat of the Swedish courts until 1682, when William Penn arrived. The spot where he landed is marked by a memorial stone, and Pusey house (built in 1683), which he occupied for a time, still stands. The old city hall (1724) is one of the oldest public buildings in the country. After the battle of Brandywine George Washington retreated to Chester, and here wrote his account of the battle. Soon after that it was occupied by the British. It was incorporated as a borough in 1701, and received a city charter in 1866. Its period of rapid growth began with the introduction of large manufacturing interests about 1850. In 1850 the population was 1,667; in 1880, 14,997; in 1900, 33,988. Between 1910 and 1920 it increased 50.6%. Annexations of territory brought the land area to 4.5 sq.mi.

CHESTER, a city of South Carolina, U.S., in the foothills of the Blue Ridge mountains, 65 mi. N.N.W. of Columbia; the county seat of Chester county. It is on federal highways 21 and 321, and is served by the Southern, the Seaboard, the Carolina and Northwestern and the Lancaster and Chester railways. The population was 6,893 in 1950 and was 6,392 in 1940 by the federal census.

The city is advantageously situated between the hydroelectric developments of the Broad and the Catawba rivers. Its manufactures include building products, cloth and yarn, flour and dairy products.

Chester was settled about 1732, was incorporated as a town in 1849 and as a city in 1893.

CHESTERFIELD, PHILIP DORMER STANHOPE, 4th EARL OF (1694–1773), son of Philip Stanhope, 3rd earl (1673–1726), and Elizabeth Savile, daughter of George Savile, marquess of Halifax, was born in London on Sept. 22, 1694. The care of the boy devolved upon his grandmother, the marchioness of Halifax. His education, began under a private tutor, was continued (1712) at Trinity Hall, Cambridge; here he remained little more than a year, but seems to have acquired a considerable knowledge of ancient and modern languages. His university training was supplemented (1714) by a continental tour, untrammelled by a governor; at The Hague his ambition for the applause awarded to adventure made a gamester of him, and at Paris he began, from the same motive, that worship of the conventional Venus, the serious inculcation of which has earned for him the largest and most unenviable part of his reputation.

The accession of George I. brought him back to England. His relative, James Stanhope (afterwards 1st Earl Stanhope), the king's favourite minister, procured for him the place of gentleman of the bedchamber to the prince of Wales. In 1715 he entered the House of Commons as Lord Stanhope of Shelford and member for St. Germans. In 1726 his father died, and Lord Stanhope became earl of Chesterfield. He took his seat in the Upper House, and his oratory, never effective in the Commons by reason of its want of force and excess of finish, at once became a power. In 1728 Chesterfield was sent to The Hague as ambassador. In this place his tact and temper, his dexterity and discrimination, enabled him to do good service, and he was rewarded with Walpole's friendship, a Garter and the place of lord high steward. In 1732 there was born to him, by a certain Mlle. du Bouchet, the son, Philip Stanhope, for whose advice and instruction were afterwards written the famous *Letters.* He negotiated the second treaty of Vienna in 1731 and in the next year, being somewhat broken in health and fortune, he resigned his embassy and returned to England. A few months' rest enabled him to resume his seat in the Lords, of which he was one of the acknowledged leaders. He supported the ministry, but his allegiance was not the blind fealty Walpole exacted of his followers. The Excise bill, the great premier's favourite measure, was vehemently opposed by him in the Lords and by his three brothers in the Commons. Walpole bent before the storm and abandoned the measure; but Chesterfield was summarily dismissed from his stewardship. For the next two years he led the opposition in the Upper House, leaving no stone unturned to effect Walpole's downfall. In 1741 he signed the protest for Walpole's dismissal and went abroad on account of his health. He visited Voltaire at Brussels and spent some time in Paris, where he associated with the younger Crébillon, Fontenelle and Montesquieu. In 1742 Walpole fell, and Carteret was his real, though not his nominal, successor. Although Walpole's administration had been overthrown largely by Chesterfield's efforts the new ministry did not count Chesterfield either in its ranks or among its supporters. He remained in opposition, distinguishing himself by the courtly bitterness of his attacks on George II., who learned to hate him

violently. In 1743 a new journal, *Old England; or, the Constitutional Journal,* appeared. For this paper Chesterfield wrote under the name of "Jeffrey Broadbottom." A number of pamphlets, in some of which Chesterfield had the help of Edmund Waller, followed. His energetic campaign against George II. and his government won the gratitude of the dowager duchess of Marlborough, who left him £20,000 as a mark of her appreciation. In 1744 the king was compelled to abandon Carteret, and the coalition or "Broad Bottom" party, led by Chesterfield and Pitt, came into office. In the troublous state of European politics the earl's conduct and experience were more useful abroad than at home, and he was sent to The Hague as ambassador a second time. The object of his mission was to persuade the Dutch to join in the War of the Austrian Succession and to arrange the details of their assistance. The success of his mission was complete; and on his return a few weeks afterwards he received the lord-lieutenancy of Ireland—a place he had long coveted.

Short as it was, Chesterfield's Irish administration was of great service to his country, and is unquestionably that part of his political life which does him most honour. To have conceived and carried out a policy, which, with certain reservations, Burke himself might have originated and owned, is no small title to regard. The earl showed himself finely capable in practice as in theory, vigorous and tolerant, a man to be feared and a leader to be followed; he took the government entirely into his own hands, repressed the jobbery traditional to the office, established schools and manufactures, and at once conciliated and kept in check the Orange and Roman Catholic factions. In 1746, however, he had to exchange the lord-lieutenancy for the place of Secretary of State. With a curious respect for those theories which his familiarity with the secret social history of France had caused him to entertain, he hoped and attempted to retain a hold over the king through the influence of Lady Yarmouth. The influence of Newcastle and Sandwich, however, was too strong for him; he was thwarted and over-reached; and in 1748 he resigned the seals. He declined any knowledge of the *Apology for a late Resignation, in a Letter from an English Gentleman to his Friend at The Hague,* which ran through four editions in 1748, but there is little doubt that he was, at least in part, the author.

The dukedom offered him by George II., whose ill-will his fine tact had overcome, was refused. He continued for some years to attend the Upper House and to take part in its proceedings. In 1751, seconded by Lord Macclesfield, president of the Royal Society, and Bradley, the eminent mathematician, he distinguished himself greatly in the debates on the calendar, and succeeded in making the new style a fact. Deafness, however, was gradually affecting him and he withdrew little by little from society and the practice of politics. In 1755 occurred the famous dispute with Johnson over the dedication to the *English Dictionary.* In 1747 Johnson sent Chesterfield, who was then Secretary of State, a prospectus of his *Dictionary,* which was acknowledged by a subscription of £10. Chesterfield apparently took no further interest in the enterprise, and the book was about to appear when he wrote two papers in the *World* in praise of it. It was said that Johnson was kept waiting in the anteroom when he called while Cibber was admitted. In any case the doctor had expected more help from a professed patron of literature, and wrote the earl the famous letter in defence of men of letters. Chesterfield's "respectable Hottentot," now identified with George, lord Lyttelton, was long supposed, though on slender grounds, to be a portrait of Johnson. During the 20 years of life that followed this episode, Chesterfield wrote and read a great deal, but went little into society.

In 1768 died Philip Stanhope, the child of so many hopes. His death was an overwhelming grief to Chesterfield, and the discovery that he had long been married to a lady of humble origin must have been galling in the extreme to his father after his careful instruction in worldly wisdom. Chesterfield, who had no children by his wife, Melusina von Schulemberg, illegitimate daughter of George I., whom he married in 1733, adopted his godson, a distant cousin, named Philip Stanhope (1755–1815), as heir to the title and estates. His famous jest (which even Johnson allowed to have merit) "Tyrawley and I have been dead these two years, but we don't choose to have it known"—is the best description possible of his humour and condition during the latter part of this period of decline. To the deafness was added blindness, but his memory and his fine manners only left him with life; his last words, "Give Dayrolles a chair," prove that he had neither forgotten his friend nor the way to receive him. He died on March 24, 1773.

As a politician and statesman, Chesterfield's fame rests on his short but brilliant administration of Ireland. As an author he was a clever essayist and epigrammatist. But he stands or falls by the *Letters to his Son,* first published by Stanhope's widow in 1774, and the *Letters to his Godson* (1890). The *Letters* are brilliantly written—full of elegant wisdom, of keen wit, of admirable portrait-painting, of exquisite observation and deduction. Against the charge of an undue insistence on the external graces of manner Chesterfield has been adequately defended by Lord Stanhope (*History,* iii. 34). Against the often iterated accusation of immorality, it should be remembered that the *Letters* reflected the morality of the age, and that their author only systematized and reduced to writing the principles of conduct by which, deliberately or unconsciously, the best and the worst of his contemporaries were governed.

See Chesterfield's *Miscellaneous Works* (2 vols. 1777); *Letters to his Son,* etc. ed. by Lord Mahon (5 vols. 1845–53, re-issued by the Navarre Society in 1926); and *Letters to his Godson* (1890) (ed. by the earl of Carnarvon). There are also eds. of the first series of letters by J. Bradshaw (3 vols. 1892) and Mr. C. Strachey (2 vols. 1901). In 1893 a biography, including numerous letters first pub. from the Newcastle Papers, was issued by Mr. W. Ernst; and in 1907 appeared an elaborate *Life* by W. H. Craig. *See* also *The Letters of Lord Chesterfield to Lord Huntingdon,* with intro. by A. F. Steuart (1923); R. Coxon, *Chesterfield and His Critics,* with selected essays and unpublished letters by Chesterfield (1925).

CHESTERFIELD, a market town and municipal borough in the Chesterfield parliamentary division of Derbyshire, England, 24 mi. N.E. of Derby by the L.M.S.R. and L.N.E.R. Pop. (1938) 64,730. Area 13.2 sq.mi. It is doubtful whether it was a Roman station. Chesterfield (Cestrefeld) owes its present name to the Saxons. It is mentioned in Domesday only as a bailiwick of Newbold. In 1204 John granted to the town all the privileges of a free borough enjoyed by Nottingham and Derby; but before this is seems to have had prescriptive borough rights. In 1598 it was incorporated by Elizabeth under the style of a mayor, six brethren and 12 capital burgesses, and was so governed till the Municipal act, 1835. In 1204 John granted two weekly markets and an annual fair of eight days at the feast of the Exaltation of the Holy Cross (Sept. 14). This fair, which is still held, is mentioned in the *quo warranto* roll of 1330. In 1266 the town was the scene of a battle between the royal forces and the barons. In 1586 it suffered from the plague, and the parliamentary forces were overthrown here during the Civil War.

Chesterfield lies at the junction of the Rother and Hipper, in an industrial district. The church of St. Mary and All Saints belongs principally to the Decorated period. It has a wooden spire, covered with lead, 230 ft. high, and possesses also an apsidal Decorated chapel. The Stephenson Memorial hall (1879) commemorates George Stephenson, the engineer. A new town hall was completed in 1938. The grammar school was founded in 1594. A technical college was opened in 1927. The industries of the town include mining, mechanical engineering, iron and brass founding and tanning. In the neighbourhood are ironstone and coal mines and sandstone quarries. There is also a manufactory of lint, cotton-wool, bandages, etc.

CHESTER-LE-STREET, urban district in the county of Durham, England, near the river Wear, where the latter changes its northward course and turns eastward to the sea. The town is 6 mi. north of Durham on the L. N. E. R. Pop. (1938) 17,080. Area 4.1 sq.mi. Chester-le-Street was a station on a branch of the Roman north road. Under the name of *Cunecastre* it was made the seat of a bishop in 883, and continued to be the head of the diocese until 995. During that time the church was the repository of the shrine of St. Cuthbert, which was then removed to Durham. The church of SS. Mary and Cuthbert has a remarkable

series of monumental tombs. The proximity of the Durham coalfield and iron works gives employment to a large section of the population, but dependence upon these industries caused considerable unemployment during the depression of the 1930s.

CHESTERTON, GILBERT KEITH (1874–1936), English journalist and author, was born in London on May 29, 1874. He was educated at St. Paul's school, where, at an unusually early age, he gained the "Milton" prize for English verse. He left school in 1891 with the idea of studying art. But though he early developed, and indeed retained, a talent for draftsmanship of a very distinctive kind, his natural bent was literary, and he went through the usual apprenticeship of free-lance journalism, occasional reviewing and work in a publisher's office.

In 1901 he married Frances Blogg. In 1900 after having produced a volume of poems, *The Wild Knight* (1900), which led good critics to expect great things of him as a poet, he became a regular contributor of signed articles to *The Speaker* and the *Daily News*. From the first he stood out as the protagonist of revolt against the *fin-de-siècle* egotism and the weary omniscience of the previous generation, expressing for it the virile contempt of normal platitudinous man in a style unconventional, swashbuckling and dogmatic. As Addison turned the weapons of fashionable folly against itself by making vice ridiculous, so Chesterton laughed loud and long at the *blasé* self-sufficiency and the dingy little failings of the late Victorian wits. Never was conventionality defended in a manner so unconventional. Hence the legend of Chesterton as a "master of paradox," which originated among older Victorian contemporaries and persisted far longer than it was reasonable to expect, partly perhaps because the subject of the legend was more tickled by it than he need have been. Chesterton's early studies in this vein were reprinted in a series of volumes, *The Defendant* (1901), *Twelve Types* (1902), and *Heretics* (1905). Meanwhile he had laid the foundations of a more enduring reputation as a literary critic by his brilliant study of Browning in the "English Men of Letters" series (*Robert Browning*, 1903). This was followed (1906) by *Charles Dickens*, which has been described as "one of the best critical studies in the language." *Orthodoxy* (1908) and *What's Wrong with the World* (1910) succeeded *Heretics* as essays in religious thought and contemporary politics. To his hatred of the Victorian pessimists there had by now been added a hatred of Victorian economics. He had begun life as an orthodox Liberal but was seized with a growing distrust of the reality of modern party politics, coupled with a fierce dislike of the industrial capitalism which he found dominant in the two old parties. He reacted, however, ultimately as fiercely from Socialism, and, in company with Hilaire Belloc and others, propagated the Distributist theories with which his name is associated.

In fiction his fancy found free play, and the medium was well suited to the expression of his ideas. He produced *The Napoleon of Notting Hill* (1904), a fantastic dream-history of civil wars between the suburbs of London, in which the shattering sanity of romantic man is once more vindicated; *The Club of Queer Trades* (1905), wherein the germs of his later success in detective fiction may be noticed; *The Man Who was Thursday* (1908), and *The Ball and the Cross* (1909). In these works the tendency to commingle his philosophy with his fiction became even greater. An earlier generation than Chesterton's would have called the books allegories, probably with the enthusiastic assent of the author. During the same period Chesterton produced a quantity of verse, some good, some bad—none of it indifferent. At its best it is very good indeed. A well-known English critic once observed of his light verse that, whereas there had been many in all ages who could write comic verse, Chesterton was one of the very few who could write comic poetry. The compliment was deserved. His more serious verse has been held to give him rank as the last of the great rhetorical poets. Like all rhetorical poets he is sometimes tinselly, but his best poems show what rhetoric can be at its best. Of these are "Lepanto" (1911) and "A Song of the Wheels," written during the railway strike of 1911. *The Ballad of the White Horse* (1911) is uneven, but contains some of his finest work.

The year before the World War saw the issue of his *Victorian Age in Literature* (1913), in which he showed that he could write a hand-book without loss of those qualities of penetrating analysis and generous appreciation which he had already brought to the work of literary criticism. An excellent example is the way in which he put the case for Swinburne, a poet with whom fundamentally he had little in common. In the same year he produced *Magic*, a fanciful play in three acts, which was deservedly successful. It is a matter for surprise and regret that he never, until 1927, followed up this initial attempt at play-writing. Detective fiction claimed him for her own, and his "Father Brown" series (1911, 1914, 1926 and 1927) and *The Man Who Knew Too Much* (1922) showed that he could couple even the writing of sensational mystery stuff with an expression of the views which he had made peculiarly his own. *The Flying Inn* (1914) is yet another of his socio-political "allegories," interspersed with what are perhaps the most charming of his light verses, afterwards republished in *Wine, Water and Song* (1915). Another work of the same kind is *Manalive* (1915).

In 1922 an event happened which was of the utmost moment in Chesterton's life. He was received into the Roman Catholic Church. It was the natural result of a spiritual and intellectual development such as his had been; and it cannot be said profoundly to have modified this development, of which it was the outcome. For the student of his works in the future it will not be necessary sharply to divide, as has to be done in some cases, his "Catholic" from his "pre-Catholic" writings. The general doctrines which he was preaching in 1927 he was preaching in 1906. *Charles Dickens* might have been written by a Catholic, and *St. Francis of Assisi* (1923) by the "pre-Catholic" Chesterton.

During the War Chesterton published little of permanent value. His volume of suggestive and brilliant historical essays, called by some strange oversight *A Short History of England* (1917), is most worthy of note. Of his later works, *The Superstition of Divorce* (1920), *The New Jerusalem* (1920), *What I saw in America* (1922), *St. Francis of Assisi* (1923), *William Cobbett* (1925), *The Everlasting Man* (1925), *The Judgment of Dr. Johnson* (1927), *R. L. Stevenson* (1927), *Generally Speaking* (1929), and *The Poet and the Lunatics* (1929) are the chief.

It is difficult in the limits of such an article to appraise Chesterton's work adequately; but it is not difficult to see how his early reaction against the ideals (or lack of ideals) of the materialist civilization of the 19th century led him inevitably to champion the causes, lost or other, which he has championed (and here, be it said, that it is difficult to imagine that any cause is lost when Chesterton is defending it). He objected not so much to the civilization (for him, too, "Romance brought up the 9.15") as to the complacency of those who thought it the only, or the highest, form of civilization. And yet he could appreciate the great Victorians as could few of his contemporaries. The generation after the War returned to Trollope and Wilkie Collins. But it was Chesterton who was showing them the way 15 years earlier. Indeed, it is this quality of appreciating his opponent, which he himself so praises in Pope, which makes the literary Chesterton at once so lovable a personality and so deadly an antagonist.

If a prediction may be ventured, Chesterton will be remembered longest by his poems and his work in literary criticism Many will regret that he tried his hand so little at play-writing, and spent so much time on polemical journalism. Nearly all will deplore the volume of his output. None will question the reality of his achievement at its highest, or the strength and purity of his influence. He died on June 14, 1936.

See *G. K. Chesterton: a Criticism* (published anonymously, 1908); "A Canterbury Pilgrim" in John Freeman, *English Portraits and Essays* (1924). (E. I. J.)

CHESTERTON, a suburb in the northeast of Cambridge borough, Cambridgeshire, England, on the river Cam. Pop. (1931) about 16,000. The church of St. Andrew is Decorated and Perpendicular, with remains of frescoes. The Cambridge university boat club and the various college boat clubs have boat-houses along the river. Market gardening is carried on in the neighbourhood. Pop. of rural district (est. 1938) 31,080.

CHESTNUT. In its true sense, this name applies only to the genus *Castanea,* which includes the following four species: (1) European chestnut, *C. sativa;* (2) American chestnut, *C. dentata;* (3) Japanese chestnut, *C. crenata,* and (4) Chinese chestnut, *C. mollissima.* Chinkapins also are members of the genus and therefore are closely related to chestnuts. There are a number of hybrids, of which none are well-known.

Chestnuts are deciduous, catkin-bearing trees of much value for many purposes. They produce food for man and many forms of animal life, tannin for the leather industry and firewood of certain value. The largest growers furnish excellent timber, much used for telephone poles, fence rails and posts, railroad ties, mine props, building material and to some extent material for interior finishing, although the grain is coarse and does not take a high polish. All species have remarkable capacity for self-replacement; that is, coppice growth springs up quickly when tops die because of disease or when trees are cut. The wood is outstanding in its resistance to decay either when exposed to weather or when in contact with soil.

There are two kinds of chestnut catkins, some of which are entirely staminate while a few others, in the upper parts of the clusters, have pistillate flowers at the base. Chestnut fruits develop from the latter as single or multiple spiny burs, with the usual number being three. Each normal bur contains three nuts, although here also there are freakish formations. All species thrive best in soils which are acid or neutral rather than strongly alkaline, loose and porous and somewhat dry. The trees are deep-rooted, and while many may die because of drought during the first one or two seasons after being transplanted, once they are well established they endure lack of soil moisture better than most species with which they are commonly associated. All occur in the less severe regions of the north temperate zone somewhat away from the seacoast. They seldom grow at altitudes of more than 4,000 ft. in Europe or the United States, 3,000 ft. in Japan or 8,000 ft. in China. No figures of nut production are available from any country.

The European chestnut is first in economic importance as its indigenous range includes much of southern Europe, northern Africa and southern Asia east to the Caucasus. It has long been grown successfully in England, Scotland, India and Australia. During the 19th century, it became widely established in the eastern parts of the United States and on the Pacific coast. It practically disappeared from the east during the first third of the 20th century, but in 1943 it was still being grown in California and the Pacific northwest. This species is probably the most massive grower of the genus, and few British writers on chestnut trees fail to mention certain individual specimens having tremendous crowns and trunks. The greatest of those so reported appears to have been the largest in a group of huge chestnut trees at the foot of Mount Etna in Sicily; this tree was estimated to have been possibly 2,000 yrs. old when it was finally destroyed by volcanic eruption. It was reported to have had a girth of 204 ft. in 1850.

The European chestnut is the principal source of chestnuts consumed in Europe and the United States. Of an average of 16,085,400 lbs. imported into the United States during the 5-year period ending June 30, 1941, 12,663,600 lbs. yearly came from Italy and 2,921,200 lbs. from Portugal. During the 5-year period ending June 30, 1936, an average of 819,000 lbs. were imported from Spain and 96,000 lbs. from France. The largest European chestnuts are called marrons. These are eaten raw, roasted or boiled. In many regions, chestnuts of secondary sizes are allowed to harden by becoming dry, after which they are ground into flour and substituted for cereals in making soups, breads and other foods. Chestnuts of the smallest sizes are used as food for livestock and wild life.

The American chestnut was once one of the nation's most valuable trees. Its original range extended from southern Maine, west to southeastern Michigan, south and west to southern Illinois, south and east to western Florida and northeast to New England, without reaching the Atlantic coast. It grew thickly over vast stretches of mountain land but thinned out rapidly at lower levels. In forests, trees often grew to 100 ft. in height and in open spaces, trunk diameters of 6–8 ft. were frequent. Maximum diameters of more than 12 ft. are authentic.

Nuts of the American chestnut are usually small in comparison with European chestnuts and less attractive in appearance because of being partially or completely covered by a gray tomentum. Among true chestnuts, however, the flavour of the American chestnut is equalled only by the Chinese chestnut, which rivals it closely. A number of varieties were named during the last decade of the 19th century, but only one—Hathaway of Michigan—was propagated to any extent.

Trees of both American and European species were largely killed throughout the entire east during the period 1900–35 by chestnut blight, a virulent fungus disease (*Endothia parasitica*) which was inadvertently introduced into the United States from the orient at the beginning of the century. Early efforts at control were made but with no practical success.

The Japanese chestnut is indigenous to Japan and Chosen. In the former country, chestnuts were important articles of food probably as early as 1700. The tree is usually a small grower, but heights of 60 ft. and trunk diameters of 3 ft. are on record. As most commonly known in the United States, where the species was introduced in 1876, the trees are precocious and prolific, and the nuts attractive in appearance, but rarely of fine texture or best flavour. Their eating qualities are much improved by boiling or roasting.

The Chinese chestnut grows to about the same size as the Japanese. Records show that it was introduced into the United States as early as 1853, but large importation and distribution of seed did not begin until the U. S. Department of Agriculture became active in this field in 1906. Between that time and the outbreak of World War II, many importations were made, and the species became well established in many quarters. The seedling trees vary greatly in form and general habit of growth, some being squat and awkward while others are tall and erect. Many are of intermediate form and therefore of the shape most desired by orchardists. As a rule the nuts are not so large as Europeans but they are of attractive, glossy appearance and very sweet. This chestnut appears to offer considerable inducement to conservative planters. The leading varieties are Bartlett, Carr, Hobson, Milford, Reliance, Stoke, Yankee and Zimmerman.

Chinkapin plants range from low shrubs to large trees, some species of which occasionally reach a height of 90 ft. The group differs from that of the chestnut mainly in that the nuts are small and single in the bur, and the burs form in racemes instead of clusters. Six species are known in the United States from middle Pennsylvania southward and two in China. (C. A. Rd.)

CHETTLE, HENRY (*c.* 1560–1607), English dramatist. In 1592 he published Robert Greene's *Groatsworth of Wit.* In the preface to his *Kind Herts Dreame* (end of 1592) he admits his editorship of that pamphlet, and incidentally he apologized to three persons (one of them commonly identified with Shakespeare) who had been abused in it. As early as 1598 Francis Meres includes him in his *Palladis Tamia* as one of the "best for comedy," and between that year and 1603 he wrote or collaborated in some 48 pieces. Of the plays usually attributed to Chettle's sole authorship only one was printed. This was *The Tragedy of Hoffmann: or a Revenge for a Father* (played 1602; printed 1631), a share in which Mr. Fleay assigns to Thomas Heywood. It has been suggested that this piece was put forward as a rival to Shakespeare's *Hamlet. The Pleasant Comedie of Patient Grissill* (1599), in which he collaborated with Thomas Dekker and William Haughton, was reprinted by the Shakespeare society in 1841. In Nov. 1599 Chettle received ten shillings for mending the first part of "Robin Hood," *i.e. The Downfall of Robert, Earl of Huntingdon,* by Anthony Munday; and in the second part, which followed soon after and was printed in the year 1601, *The Death of Robert, Earle of Huntingdon,* he collaborated with Munday. Both plays are printed in Dodsley's *Select Collection of Old English Plays* (edited by W. C. Hazlitt, volume viii). Chettle died before the appearance of Dekker's *Knight's*

Conjuring in 1607, for he is there mentioned as a recent arrival in limbo.

Hoffmann was edited by H. B(arrett) L(ennard) (1852), by Richard Ackermann (Bamberg, 1894), and J. S. Farmer in *Old English Plays, Students' Facsimile Edition* (1913).

CHETWODE, PHILIP WALHOUSE CHETWODE, 1ST BARON (1869–1950), British soldier, was born Sept. 21, 1869, and in 1889 was commissioned to the 19th Hussars from the militia. He saw active service in Burma and South Africa, and later became assistant military secretary to Sir John French at Aldershot. In 1905 he succeeded his father as 7th baronet. Promoted to the command of the 5th cavalry brigade in May 1914, his brigade accompanied the expeditionary force to France and helped to cover the retreat from Mons, bringing off at Cérizy one of the rare cavalry charges of World War I. He went to Egypt to command the desert column in 1916, and won distinction by the decisive surprise attack at Rafah, which finally freed Sinai from the Turks. After the second battle of Gaza in April 1917 he succeeded Gen. Dobell in command of the whole eastern force. When Gen. Allenby came out to take over the supreme command he based his plan on Chetwode's plans, and the latter, commanding the 20th army corps after the reorganization of the forces, played a distinguished part in the advance to Jerusalem and in the crowning victory in Sept. 1918. In Sept. 1920 Chetwode succeeded Gen. Harington as deputy chief of the imperial staff, and two years later became adjutant general to the forces. He was commander-in-chief of the army in India from 1930 to 1935. Sir Philip was gazetted field marshal in 1933. He was created baron in 1945. He died in London July 6, 1950.

CHEVALIER, ALBERT (1861–1923), English music-hall artist, began his connection with the variety stage while still a child. In 1869 he appeared at a "penny-reading" at Cornwall Hall, Notting Hill. After a brief experience as a clerk in a newspaper office, and as a pupil teacher, he appeared for a short time in 1877 with the Kendals and the Bancrofts. For some time he played "legitimate" parts with Hare (*q.v.*), Willie Edouin and others, and during his association with Edouin (1888–89) at the Strand theatre he introduced in burlesque his first cockney song, "Our 'armonic Club." The year 1891 was the turning point of his career, when he deserted the "legitimate" stage and appeared at the London Pavilion as a music-hall entertainer. Thereafter he speedily won the place to which his genius entitled him, among the first artistes of his generation. He toured throughout Great Britain and the United States, and in addition gave over 1,000 special recitals at the small Queen's Hall. As singer, composer or part composer, his name is associated with between 70 and 80 songs. In addition he wrote some 14 plays and sketches. In 1906 he appeared with Yvette Guilbert at the Duke of York's theatre, and in the name part of Sir James Barrie's *Pantaloon*. His last appearance was in Nov. 1922, in a play, *My Old Dutch*, written by himself and Arthur Shirley on the basis of his own famous song. He died on July 10, 1923. Chevalier's best known songs are: "Mrs. 'Enery 'Awkins," "Knocked 'em in the Old Kent Road," "My Old Dutch," "A Fallen Star," "Our Little Nipper," "Fair Flo." He wrote two records of his own experiences, *Before I Forget* (1901), and *Uninitiated* (1906).

In his own special line Chevalier is generally recognized as being an artist of the first rank. While not possessing the vast range of a Marie Lloyd, he yet developed his own specialty as it had never before been developed, and presented real character sketches of the life of the people, emphasizing the grave as well as the gay and bringing tears as readily as laughter. Subsequent cockney comedians have imitated his humour. None has even endeavoured to compete with him in the delineation of the pathetic. Another striking feature of his songs was the tuneful and haunting melodies to which they were set. This was a real feature of the music-hall stage in an era when the comedian tended to sing his patter to the baldest of extemporizations. (E. I. J.)

CHEVALIER, MICHEL (1806–1879), French economist, was born at Limoges. In his early manhood, while employed as an engineer, he became a convert to the theories of Saint-Simon; these he ardently advocated in the *Globe*, the organ of the Saint Simonians, which he edited until his arrest in 1832 on a charge of outraging public morality by its publication. He was sentenced to a year's imprisonment, but was released in six months through the intervention of Thiers, who sent him on a special mission to the United States to study the question of land and water transport. In 1836 he published the letters he wrote from America to the *Journal des Débats*, as *Lettres sur l'Amérique du Nord*, and in 1838 published *Des intérêts matériels de la France*. In 1850 he became a member of the Institute, and in 1851 published his *Examen du système commercial connu sous le nom de système protecteur*. He played an important part in bringing about the conclusion of the Cobden commercial treaty between France and Great Britain in 1860. He became a member of the Senate in 1860.

Among his other works are: *Cours d'économie politique* (1842–50); *Essais de politique industrielle* (1843); *De la baisse probable d'or* (1859, translated into English by Cobden, *On the Probable Fall of the Value of Gold*, Manchester, 1859); *L'Expédition du Mexique* (1862); *Introduction aux rapports du jury international* (1868).

CHEVALIER, ULYSSE (1841–1923), French bibliographer, was born at Rambouillet on Feb. 24, 1841. He published a great number of documents relating to the history of Dauphiné, *e.g.*, the cartularies of the church and the town of Die (1868), of the abbey of St. André-le-Bas at Vienne (1869), of the abbey of Notre Dame at Bonnevaux in the diocese of Vienne (1889), of the abbey of St. Chaffre at Le Monestier (1884), the inventories and several collections of archives of the dauphins of Viennais, and a *Bibliothèque liturgique* in six volumes (1893–97), the third and fourth volumes of which constitute the *Repertorium hymnologicum*, containing more than 20,000 articles. But his principal work is the *Répertoire des sources historiques du moyen âge*.

The first part of the *Répertoire, bio-bibliographie* (1877–78; 2nd ed., 1905), contains the names of all the historical personages alive between the years 1 and 1500 who are mentioned in printed books, together with the precise indication of all the places where they are mentioned. The second part, *Topo-bibliographie* (1894–1903), contains not only the names of places mentioned in books on the history of the middle ages, but, in a general way, everything not included in the *Bio-bibliographie*. The *Répertoire* is one of the most important bibliographical monuments ever devoted to the study of mediaeval history.

CHEVALIER, literally, a horseman. In feudal times the term was equivalent to knight (*see* KNIGHTHOOD AND CHIVALRY), and later it was also employed in France for the cadets of noble families, where it is still used for the lowest rank of certain orders, as Chevalier of the Legion of Hanover. The appellation of *Chevalier of St. George* was given to James Stuart, son of James II., the Old Pretender, and that of *The Young Chevalier* to Prince Charles Edward Stuart, the Young Pretender. The Seigneur de Bayard (*q.v.*) was known as the *Chevalier sans peur et sans reproche*.

CHEVAUX-DE-FRISE, a military obstacle, originating apparently in the Dutch War of Independence, and used to close the breach of a fortress, streets (French for "Friesland horses" the Dutch *Vriesse ruyters*, "Frisian horsemen," and German *Spanische Reiter*, "Spanish horsemen"), etc. It was formerly often used in field operations as a defence against cavalry; hence the name, as the Dutch were weak in the mounted arm and had therefore to check the enemy's cavalry by an artificial obstacle. Chevaux-de-frise form an obstacle about 4 feet high, made of beams in which are fixed a number of spears, sword-blades, etc., with the points projecting outwards on all sides.

CHEVERUS, JEAN LEFEBVRE DE (1768–1836), French ecclesiastic, was born on Jan. 28, 1768, in Mayenne, France. He was made canon of the cathedral of Le Mans and began to act as vicar to his uncle in Mayenne, but owing to the Revolution he emigrated in 1792 to England, and thence in 1796 to Boston (Mass.). He spent several months in the Penobscot and Passamaquoddy missions and visited scattered Catholics. During the epidemic of yellow fever in 1798 he won great praise for his courage and charity; and his preaching attracted many

Protestants. In 1808 the pope made Boston a bishopric, suffragan to Baltimore, and Cheverus its bishop. Ill-health caused him to resign his bishopric and in 1823, Louis XVIII having insisted on his return to France, Cheverus became bishop of Montauban. He was made archbishop of Bordeaux in 1826; and in Feb. 1836, in accordance with the wish of Louis Philippe, he was made a cardinal, only five months before his death, which took place in Bordeaux on July 19, 1836.

See J. Huen-Dubourg, *Vie du cardinal de Cheverus* (Bordeaux, 1838); Eng. version by E. Stewart (Boston, 1839).

CHEVÉ SYSTEM. A method of teaching music to children in wide use in France. It is somewhat akin to the Tonic Sol-fa system, being based, like that, on the principle of a movable tonic as opposed to the older "fixed Do" method, but employs numerals for the written signs of the different notes instead of the sol-fa syllables, although the latter are retained for vocal purposes. The system was invented by a French mathematical professor, Pierre Galin (1786–1821); developed and advocated by one of his followers, Aimé Paris (1798–1866); and perfected and popularized, after much controversy and opposition, by the latter's brother-in-law, Émile Joseph Maurice Chevé (1804–64).

CHEVET, in architecture, the entire eastern termination of a church choir (*q.v.*), a term used especially for churches with apses (*q.v.*); also an ambulatory (*q.v.*) from which a series of radiating chapels open. It is a distinctly French development, appearing in a highly organized form in many 12th-century Romanesque churches; *e.g.*, Notre Dame du Port, Clermont-Ferrand and St. Paul, Issoire. It resulted from attempts to place as many subsidiary altars in chapels as possible, in close association with the high altar and the procession path around it. The development of the chevet produced many spaces of unusual shape whose vaulting was one of the great incentives toward the evolution of the ribbed and pointed vault; the chevet, therefore, plays an important part in the transition from Romanesque to Gothic. The radiating chapels are usually uneven in number, and the central one is frequently much larger than the others, dedicated to the Virgin Mary and known as the Lady chapel.

CHEVIOT, an incorporated city of Hamilton county, O., U.S., adjoining Cincinnati to the west, on the Chesapeake and Ohio railway. Pop. (1950) 9,944. It is a residential suburb. The village was incorporated in 1901. It was laid out in 1818 by John Craig, Sr., and was named after his native Cheviot hills of Scotland. It was first settled in 1805 by Enoch Carson.

CHEVIOT CLOTH. A woollen fabric made originally from the wool of the well-known breed of Cheviot sheep, and now made from other types of wool. Cheviot wool possesses good spinning qualities, since the staple is of a fine, soft and pliable character. The true Cheviot type of fabric has a crispness of texture similar to serge cloth (*q.v.*) except that it is of a slightly rougher and heavier type. Cheviot fabric may be produced either from woollen or worsted yarns according to the character and texture or feel desired in the finished fabric. Some qualities are produced from cross-bred worsted yarns which are adapted for furnishing the crispness of texture which is one of the distinguishing characteristics of the true Cheviot type of fabric. Cheviot suitings for sports wear are made from the harder spun worsted yarns, while some qualities are also made from Botany worsted. So-called cheviot suitings of inferior quality contain an admixture of cotton, while other low-grade cheviots are weighted with flocks. A stout, twilled, cotton fabric made from cotton warp and weft of coarse counts of yarn and woven with small dobby patterns or with fancy warp stripes, of brown or blue, with bleached weft, is also described as cheviot shirting. (H. N.)

CHEVIOT HILLS, a range forming about 35 mi. of the border between England and Scotland. The boundary generally follows the line of greatest elevation, but as the slope is more gradual southward than northward the larger part of the range is in Northumberland, Eng., and the lesser in Roxburghshire, Scot. The axis runs from northeast to southwest, with a northward tendency at the eastern end where the ridge culminates in the Cheviot, 2,676 ft. Its chief elevations from this point southwestward fall abruptly to 2,034 ft. in Windygate hill, and then more gradually to about 1,600 ft. above the pass, followed by a high road from Redesdale. Beyond this are Carter Fell (1,815 ft.) and Peel Fell (1,975 ft.), after which two lines of lesser elevation branch westward and southward to enclose Liddesdale. The rocks include Silurian, Old Red Sandstone (with lavas) and Carboniferous strata, and the hills are finely grouped, of conical and high-arched forms, and generally grass covered. Their flanks are scored with deep narrow glens in every direction, carrying the headwaters of the Till, Coquet and North Tyne on the south, and tributaries of the Tweed on the north. The range is famous for a valuable breed of sheep. It was the scene of many episodes of border warfare, and its name is associated with the ballad of *Chevy Chase*. The main route into Scotland from England lies along the low coastal belt east of the Till; the Till itself provided another and Redesdale a third. There are numerous ruins of castles and forts on the English side in this district.

CHEVRON, any ornament formed of two slanting lines meeting at an angle. In heraldry it is a bent bar. It is also one of the most common distinguishing marks for military and naval uniforms, where it is placed on the sleeves and serves either as a mark of honour or to indicate a special function. In architecture, the term is sometimes applied to the angle formed by the meeting rafters of a roof, but it is more commonly used for the purely decorative form. Chevrons joined together zigzag are one of the commonest of Romanesque geometric ornaments, especially in areas under Norman influence. It is a frequent decoration for arch mouldings and column shafts. The chevron appears early in primitive work and is found on pottery all over the world. It also occurs frequently in textiles, on Egyptian walls and ceilings and in Aegean art as a column decoration; *e.g.*, Tholos of Atreus at Mycenae, *c.* 1200 B.C. (For military use *see* INSIGNIA, MILITARY.)

CHEVROTAIN or MOUSE DEER, the representatives of the family Tragulidae. These tiny animals are not true deer, but constitute a special section of artiodactyles known as Tragulina (*see* ARTIODACTYLA). The typical genus, *Tragulus*, which is Asiatic, contains the smallest representatives of the family, the animals having more of the general aspects and habits of rodents than of ruminants. A number of species are known, inhabiting the Malay peninsula, the Malay archipelago, Ceylon and India. The second genus, *Hyemoschus*, is African, and distinguished by the feet being stouter and shorter, the outer toes better developed and the two middle metacarpals not welded together. The only existing species, *H. aquaticus*, is larger than any of the Asiatic chevrotains, which it otherwise resembles, but is said to frequent banks of streams and have much the habits of pigs. It is rich brown, spotted and striped with white. Remains of a form chiefly differing in size (*Dorcatherium*) have been found in the Miocene deposits of France.

CHEVROTAIN, OR MOUSE DEER, A TINY ANIMAL ABOUT THE SIZE OF A RABBIT

CHEWING GUM. Chewing gum is a confection product prepared from chicle and similar resilient substances, combined with sweetening and flavouring. For many centuries past, the Mayans and other Central Americans chewed chicle, the coagulated milky juice (latex) of the sapodilla tree, just as people in many lands chewed various resins, leaves and grasses for relaxation and enjoyment. From the Indians of New England, the American colonists learned to chew spruce tree resins, and spruce gum was marketed in the United States in the early 1800s as the first commercial chewing gum. Later, chewing gum made of paraffin wax was introduced. In the 1860s, the use of chicle as a chewing gum base was developed. Its resilient chewing quality and ability to carry flavours won preference for this type of gum and paved the way for the major rise in the popularity of chewing gum which began in the early 1900s with the advent of modern processing, packaging and promotional methods.

Modern chewing gum consists, by weight, of approximately 20% gum base, 19% corn syrup, 60% sugar and 1% flavouring. To insure uniform chewing texture, gum base may be blended of as many as 25 latex products and like materials. The latex products are obtained from trees growing wild in tropical forests. The trees are tapped with grooved cuts from which the latex flows into containers. The latex is then collected, boiled down and moulded into blocks. Chicle from Central America, leche caspi and sorva from the Amazon valley, and jelutong from British Borneo and Indonesia, are principal types of latex products used. Synthesized preparations having similar properties, such as vinyl resins and microcrystalline waxes, have been developed for use in combination with the tropical latex products. In the manufacturing process, the gum base ingredients are washed, ground, sterilized and blended. In mixing kettles, the melted base is combined with corn syrup, sugar and flavouring. The doughlike mixture is then rolled into sheets, and divided into sticks or pellets. Essential oils from mint plants—peppermint and spearmint—provide the two leading flavours. In food content, one stick of gum contains nine calories.

The use of chewing gum rises in periods of social tension, and it increased rapidly during and after World Wars I and II. In the United States annual per capita consumption went from 39 sticks in 1914 to 89 in 1924; from 98 in 1939 to 165 in 1953. In the latter year, there were 109 chewing gum factories in the world, located in 31 countries. Of these, 33 were in the United States and 10 in Great Britain. The English-speaking and Latin-American countries are the largest chewing gum consumers. Second to the United States in per capita consumption is Canada.

(P. H. E.)

CHEYENNE. This Algonkin tribe of the Great Plains, in Minnesota in the 17th century, drifted gradually westward and is now on reservations in Montana and Oklahoma. Their speech is closer than either Blackfoot or Arapaho to the central Algonkin dialects, so that their divergence from the main body of the family is evidently relatively late. After about 1850 the Sutaio, speaking a Cheyenne dialect, were part of the tribe, though in 1804 they were still separate. The Cheyenne took a leading part in the Custer massacre of 1876. They were a typical plains tribe—brave, warlike, nonagricultural, roving after buffalo or for adventure; they show the physical type at its best, being perhaps the tallest tribe in the area. The tribal fetish was a set of four sacred arrows. In 1945 the population was 4,815.

See Mooney, *Am. Anthr. Assoc. Mem.*, vol. i (1907); George Bird Grinnell, *The Cheyenne Indians*, 2 vol. (New Haven, 1923).

CHEYENNE, capital of Wyoming, U.S., and county seat of Laramie county; near the southeast corner of the state, on rolling plains east of the Laramie range, at an altitude of 6,062 ft. It is on federal highways 30, 85 and 87; is served by the Burlington, the Colorado and Southern and the Union Pacific railways; and is an important point on transcontinental air lines. Pop. (1950) 31,935; (1940) 22,474. The Union Pacific has extensive shops there, and there are meat-packing plants, brickyards and various other industries. The city is a supply point for an extensive grazing and dry-farming area, and ships quantities of cattle. The Frontier Days celebration, held for five days each summer, is a festival at which Indians, cowboys and plainsmen from Canada to Texas gather to give exhibitions of bronco busting, steer tying, Indian dances and other characteristic features of life in the old "wild west." Just northwest is Fort F. E. Warren and its manoeuvre reserve of 52,000 ac. Cheyenne was founded in 1867, when the Union Pacific reached the spot. It was made the capital of the state and was incorporated in 1869.

CHÉZY, ANTOINE LÉONARD DE (1773–1832), French orientalist, born at Neuilly on Jan. 15, 1773. He was the first occupant of the chair of Sanskrit in the Collège Royal de France (1815), at that time the only chair of Sanskrit in Europe. Among his works were *Medjnoun et Leila* (1807), from the Persian; *Yadjnadatta-badha* (1814) and *La Reconnaissance de Sacountala* (1830), from the Sanskrit; *L'Anthologie érotique d' Amarou* (1831), published under the pseudonym A. L. Apudy.

See the *Memoires* of the Académie des Inscriptions (new series, vol. xii), where there is a notice of Chézy by Silvestre.

CHHATARPUR, a town and district of Vindhya Pradesh, India. The town (pop. 1941, 13,210) is 70 mi. by road southwest of Banda on the Gwalior-Allahabad railway line; it was named after Chhatar Sal, the founder of Bundelkhand independence, and contains his cenotaph. Paper and coarse cutlery are manufactured. The town is the seat of a college of Agra university.

CHHATARPUR DISTRICT absorbed on Jan. 1, 1950, the former princely state of Chhatarpur (area 1,170 sq.mi.; pop. 1941, 184,720), which during British rule had been in the Bundelkhand subagency of the Central India agency. The population of the district was 481,140 according to the 1951 census. The state was founded in the 18th century by Kunwar Sone Sah, a Rajput of the Ponwar clan. On the establishment of British supremacy in Bundelkhand he received a *sanad* in 1806 confirming him in the possession of his state. In 1854 it would have lapsed to the British government for want of direct heirs but, in 1862, because of the loyalty of the Chhatarpur chiefs during the mutiny, it was conferred on Jagat Ray. (C. C. D.)

CHHATTISGARH, a natural region of south-central India, an administrative division of Madhya Pradesh and a former states agency. Chhattisgarh is a huge, undulating laterite plain, treeless except for the mango groves planted by generations of villagers round the village sites. The formation of the country and the soil are distinct from all other parts of Madhya Pradesh. On the crests of the undulations the red laterite, locally known as *bhata*, comes to the surface. In the depressions between these crests is black soil, gradually turning to brown and then to yellow as the ground rises. The Mahanadi river flows north and east across the division on its way to the Bay of Bengal.

In the past Chhattisgarh was remote and isolated, being shut off by the Maikal range from the Nagpur division on the west and by miles of hills and forests in the wilder states bordering it on the north, east and south. This isolation allowed a very ancient dynasty, the Hai Hai Bansis of Raipur and Ratanpur, to remain undisturbed for about seven centuries, but in 1743 Maratha forces took the country without a blow. (For its history thereafter *see* CENTRAL PROVINCES AND BERAR.) The division now comprises six districts: Bastar, Bilaspur, Drug (Durg), Raigarh, Raipur and Sirguja (Surguja).

Aboriginals occupied the hilly and jungly surroundings of the great plain. The open country is populated by Hindu castes and outcasts, of whom the Chamars, originally leatherworkers but now cultivators, in the 19th century under reforming leaders revolted against the oppression of the Brahmins and high-caste Hindus. The "Satnami" Chamars, as they are called, worshippers of the "true Name" (Satnam) are monotheists and total abstainers from alcohol, some sections also prohibiting tobacco. They freely slaughter cattle and have other customs repugnant to Hindus; between Chamars and Hindus there is hereditary hostility. There are also in Chhattisgarh many disciples of the saint Kabir (Kabirpanthis; *q.v.*), but this sect is not peculiar to the division.

The division covers an area of 40,434 sq.mi. and had a population in 1951 of 6,408,524. Satnami Chamars number nearly 500,000; Hindus proper and animists preponderate. The Chhattisgarh peasant (ryot) speaks a corrupt dialect of Hindi, akin to the dialect of Baghelkhand.

The laterite ridges of Chhattisgarh are either barren or produce nothing but catch crops of coarse rice when the rains are favourable. The depressions between are more fertile and often rich. The rich soils also are mainly under rice, but produce a second crop of pulses and oilseeds if the late rains are propitious. The western part of the plain produces a fair amount of wheat and cold-weather field crops.

The great rice crop of Chhattisgarh was once almost at the mercy of a droughty season, being broadcasted and unirrigated. It is a country with thousands of shallow village tanks unsuited for irrigation, wells are comparatively few and tank water is used indiscriminately for men and cattle, both for drinking and washing purposes. Wells are sparingly used, even when constructed at the expense of public funds, as the water is pronounced "taste-

less." As a consequence, cholera is likely to be rife in the hot season and at its worst in times of drought and famine. The railway and government irrigation works have worked wonders in improving the country, and education has made considerable though slow progress. Chhattisgarh has often been described as one of the granaries of India, but lack of irrigation, rough cultivation and excessive fragmentation of holdings, whereby one man holds numbers of tiny, scattered rice plots instead of compact holdings, has resulted in precarious and most uneconomical agriculture. Many storage tanks have been constructed by the government in Raipur and Drug districts and a few in Bilaspur, and after 1914 two major works, the Mahanadi and Tendula canals enabled very large areas to receive protection. Large works were also constructed at Bilaspur, but the people are very slow in learning how to utilize irrigation to the best purpose.

Under British paramountcy the Chhattisgarh States Agency, a subagency of the Eastern States Agency, comprised Bastar, Chhuikhadan, Jashpur, Kalahandi, Kanker (Kankar), Kawardha, Khairagarh, Korea, Patna, Raigarh, Sakti, Sirguja, Changbhakar, Nandgaon, Sarangarh and Udaipur states. Following the independence of India, Kalahandi and Patna were merged with Orissa state and the remainder with Madhya Pradesh on Jan. 1, 1948. The total area of the subagency was 37,688 sq.mi.; total pop. (1941) 4,050,000. The headquarters of the states agency, like those of the division, were at Raipur.

CHHINDWARA, a town and district in the Nagpur division of Madhya Pradesh, India. The town (pop., 1951, 27,652), 64 mi. N.N.W. of Nagpur, is the district headquarters and a market town with small local industries; situated on the Satpura plateau about 2,000 ft. above sea level, it is a pleasant place with a fairly temperate climate. It is connected by the Central railway with Betul, Nagpur and Jubbulpore.

CHHINDWARA DISTRICT (area 7,794 sq.mi.) had a population in 1951 of 1,080,491; about 75% were Hindus and most of the rest Gonds and other aboriginal tribes. In the north of the district, bordering the Mahadeo range and Hoshangabad district, are hills rising to about 3,000 ft. and containing some sal forest. The rugged country immediately south of the hills constitutes the *Jagirs* or feudal estates of the Gond chiefs, who once preyed upon travellers and raided the open country on their borders. South of the *Jagirs* is the more level Satpura plateau, extending from Betul in the west to Seoni in the east and drained by the Pench and Kanhan rivers. The southern and eastern parts of the plateau include the fertile wheat plain of Chaurai. On the south again the country drops into the Nagpur plain, to which it geographically belongs. This is a rich cotton and *jowar* (big millet) area and is the richest and most populous part of the district; the language of the area is Marathi. On the southeast the plateau, here called the Lahmarpani, projects into the plain, and this part is noted for its breed of cattle. The lowlands of the district are hot and the uplands have a temperate climate. There are fairly extensive coal fields to the north of Chhindwara, connected by narrow-gauge railway with that town and by broad-gauge line with Betul. In the south, near the Nagpur district border, are valuable deposits of manganese.

CHIABRERA, GABRIELLO (1552–1638), Italian poet, was born at Savona, It. He studied philosophy at the Jesuits' college in Rome and entered the household of a cardinal. He mixed in the literary society of his day, but presently was drawn into a quarrel which compelled him to leave Rome. He retired to Savona, where he read Pindar and Anacreon and, no doubt, Pierre de Ronsard. He determined to enrich Italian poetry with new forms, and his imitations from the classics include some successful innovations in Italian verse, which were adopted by the lyrists of the next century. The mass of Chiabrera's work is great: epics, pastorals, odes, lyrics, satires, dramas and religious and didactic poems. His best poetry, however, is to be found not in his more ambitious works but in his gracefully musical *canzonette*, described as *anacreontiche*. His autobiographical sketch is also extremely interesting. The simple old poet, with his adoration of Greek (when a thing pleased him greatly he was wont to talk of it as "Greek poetry"), his delight in journeys and sightseeing, his dislike for literary talk save with intimates and equals, his vanities and vengeances, his pride in the memory of favours bestowed on him by popes and princes and his quiet Christianity, is a figure deserving perhaps of more study than is likely to be bestowed on his work in grafting a new Hellenic style onto Italian poetry or on that "new world" of art which he fancied his own.

BIBLIOGRAPHY.—Editions of Chiabrera's works are those of Rome, 3 vol. (1718), of Venice, 4 vol. (1730), of Leghorn, 5 vol. (1781), and of Milan, 3 vol. (1807). *See* also G. Taccetta, *Gabriello Chiabrera e la sua produzione epica* (Catania, 1921); F. Neri, *Il Chiabrera e la Pléiade française* (Turin, 1920); F. L. Mannucci, *La Lirica di G. C.* (Naples, 1925); E. N. Girardi, *Esperienza e poesia di Gabriello Chiabrera* (Milan, 1950).

CHIANA (anc. CLANIS), a river which rises in the Apennines south of Arezzo, It., runs through the valley of Chiusi and, after receiving the Paglia just below Orvieto, falls into the Tiber after a course of 60 mi. In Roman times it often caused floods in the valley of Clusium. In the middle ages the whole of its valley from Arezzo to Chiusi was an uninhabitable swamp; but at the end of the 18th century the engineer Count Fossombroni moved the watershed about 25 mi. farther south, so its waters now flow partly into the Arno and partly into the Tiber.

CHIANG KAI-SHEK (or CHIANG CHIEH-SHIH; CHIANG CHUNG-SHENG) (1887–), Chinese soldier and statesman, was born in a village near Ningpo, not far from Shanghai, in the province of Chekiang. He was thus a native of southeast China, where the inhabitants differ somewhat from the other Chinese as regards both culture and language. Chiang's forebears were middle-class farmers and merchants, but he early decided upon a military career. In spite of his southern background he was accepted as a cadet in the newly established Paoting Military academy. In 1907 he was sent by the Chinese imperial government to Japan to complete his military education. While in Japan Chiang came under the influence of some Chinese expatriates, Cantonese for the most part, who were followers of the radical revolutionary leader Sun Yat-sen.

When the Chinese revolution broke out in 1911, Chiang secretly made his way back to China to aid the revolutionary cause. Though the revolution was successful, Chiang gained nothing personally, as he remained loyal to the group led by Sun Yat-sen, which was soon ousted from all governmental posts in the new republic headed by Yuan Shih-k'ai. In the years which followed, Sun continued to agitate against the new regime in the hope of establishing a more radical type of government. For some time Chiang remained a minor and rather obscure military official in the employ of Sun's revolutionary group, now known as the Kuomintang or Nationalist party. By 1920, however, most of Chiang's immediate superiors were either dead or in disgrace, and Chiang became one of Sun's most trusted and influential assistants. By this time Sun, though not a Communist, had decided to work in close co-operation with the Soviet government. On his order Chiang made a brief visit to Russia to study the Soviet military organization and on his return to China was made head of the Whampoa Military academy for the training of officers for the revolutionary or Kuomintang army. Whampoa was near Canton, which by this time had passed under Kuomintang control. Chiang soon became suspicious of the Russians, but they continued to exert strong influence over both the Whampoa academy and the higher echelons of the Kuomintang army. For a time it looked as if the Russian agents Michael Borodin and B. K. Galen would become the real leaders of the revolutionary movement, but Chiang managed to keep some check upon their powers.

In 1925 Sun Yat-sen died, and Chiang soon became recognized as one of Sun's principal political heirs. He secured the appointment as commander in chief of the Kuomintang army. By the end of the year he had brought the whole of Kwangtung and Kwangsi provinces under the control of the Kuomintang executive committee. In 1926 Chiang made his amazing advance northward through Hunan to the Yangtze river. In the following months the Kuomintang secured control over all the important cities in the Yangtze valley. This great military success was marred by internal dissensions. The Kuomintang had long included a number of different groups and cliques; the two most

important were a left-wing group willing to follow Russian Communist leadership, and a right-wing group which demanded social and economic change but which was definitely anticommunist and looked to Chiang for leadership. In 1927, after lengthy political and military manoeuvres, the right-wing or Chiang group won control over the party organization. The Soviet agents were sent back to the U.S.S.R. and a national capital was set up at Nanking, where Chiang had established military control. Some party leaders continued to express dissatisfaction, however, and in Aug. 1927 he announced his resignation, though he continued to play an active role behind the scenes.

While still in his teens Chiang had married a girl from his native village. He had long since divorced her, though retaining custody of the two sons born of this marriage. In 1927, while still in nominal retirement, Chiang was married for a second time, to Soong Mei-ling, sister-in-law of Sun Yat-sen, thus further identifying himself with the constitutional element in the Kuomintang. Eventually, through his wife's influence, Chiang was persuaded to become a Christian, joining the Methodist Church.

As he had anticipated, all sections of the Kuomintang soon felt the need of Chiang's military leadership, and in 1928 internal differences were glossed over and Chiang was recalled to serve as commander in chief (or generalissimo) of the revolutionary army, and thereafter he remained in effective control of the Kuomintang government, though at some periods he was content with real power and permitted other persons to assume nominal leadership. In 1928 the Kuomintang army again drove north and this time succeeded in capturing Peking, the ancient capital. By this action China was, in name, reunited under a single government. In point of fact, however, even when Chiang was at the height of his power the Kuomintang never had effective control over the whole of China. In some of the outlying provinces semi-independent war lords remained in power, though such men were persuaded to join the party and in theory ruled as deputies of the Kuomintang government. More serious trouble came from the Communists.

After the collapse of the left-wing branch of the Kuomintang, a few fanatical Chinese Communists, led by Mao Tse-tung determined to establish a state and a government of their own, and as time went on they were joined by an appreciable number of disgruntled intellectuals and dissatisfied peasants. At first Communist activity centred in a small area of southeastern China, but in 1935 the Communists migrated in a body to northwestern China, where the terrain was more defensible and where it was easier to maintain contact with the Russians.

For a time the most serious threat to Chiang's government came from the Japanese. In 1931 Japan seized control of Manchuria and in the following years seriously threatened other portions of northeastern China. In consequence there was considerable pressure on Chiang to cease all operations against the Communists and even to join with them in opposing the Japanese. Affairs reached a head in Dec. 1936 with the "kidnapping" of Chiang by Chang Hsüeh-liang, with the idea of forcing Chiang to join the Communists in a united front. Chiang was subsequently released without making any commitments, but for several years thereafter the Nationalists and the Communists had a tacit understanding that the major effort of both groups would be concentrated on the common enemy. These efforts were not successful. In 1937 Japan began a major war on China and won a number of important victories, occupying most of eastern China. Chiang was forced after several moves to locate his capital in Chungking in the far west. Chiang was now in a desperate condition, but he refused to come to terms with the invaders. His position was greatly helped by the entrance of the United States into the Pacific war in Dec. 1941. Japan's surrender in 1945 removed one major threat to Chiang's regime, and the Kuomintang was soon able to reoccupy a large portion of China.

Attempts were then made at political reform, and a new democratic constitution was adopted in 1946 which permitted groups outside the Kuomintang to participate in the functions of government. In 1948 under the operations of this constitution Chiang was elected president. Meanwhile the Communist menace continued to grow in magnitude, in spite of the efforts made by the U.S. to induce the Nationalists and the Communists to form a coalition government. With Soviet aid the Communists were able to secure Manchuria and seize great quantities of war material which the Japanese had left behind, while the Nationalists were not able to secure adequate supplies. In 1948 the Communists marched south and by the end of the year had control over most of China north of the Yangtze. In view of the desperate military situation Chiang retired from the presidency in Jan. 1949. The vice-president, Li Tsung-jen, became acting president with the hope that he would be able to negotiate a peace with the Communists on honourable terms. These hopes were soon blasted as the Communists demanded unconditional surrender, and when this was refused they crossed the Yangtze and began the conquest of south China. They were uniformly successful, and in a few months Nationalist resistance in China proper collapsed. Many Nationalist leaders, in despair, accepted Communist domination, but in Dec. 1949 Chiang re-emerged from retirement and established headquarters in Formosa (Taiwan), which thus became the bastion of noncommunist China. He was followed by the more intrepid of the Kuomintang leaders and by about 500,000 Nationalist troops. In the following years the government was thoroughly reorganized and numerous political and economic reforms were carried out, including the distribution of land among the peasants. Chiang was re-elected president in 1954; the U.S. and several other countries continued to recognize Chiang as the head of the legal Chinese government. After 1950 the U.S. also gave the Chiang regime substantial economic and military aid. (W. M. McG.)

CHIAPAS, a Pacific coast state of southern Mexico on the Guatemalan frontier, bounded by the states of Tabasco on the north and Veracruz and Oaxaca on the west. Pop. (1950) 907,026, largely Indians; area 28,732 sq.mi., largely forested. The Sierra Madre crosses the southern part of the state parallel with the coast, separating the low, humid, forested districts on the frontier of Tobasco from the hot, drier, coastal plain on the Pacific. The mountain region includes a fertile temperate plateau which is one of the best parts of Mexico and contains the large part of the population of the state, but isolation and lack of transportation facilities have retarded its development.

The extension across the state to the Guatemalan frontier of the Pan-American railway (from Ixtepec, on the Tehuantepec national line) and the Inter-American highway improved the industrial and social conditions of the people. The principal industries are agriculture, which is very backward, stock raising, timber cutting, fruit farming and saltmaking. Coffee is cultivated on the Pacific slope of the Sierra Madre at elevations of 2,000 to 4,000 ft., and production has met with considerable success. Rubber plantations have also been laid out, principally by U.S. companies. The exports include mahogany, dyewoods, cattle, hides, coffee, rubber, fruit and salt. The mineral resources include gold, silver, copper and petroleum. The capital, Tuxtla Gutierrez (pop. 15,883), is on the plateau, 3½ mi. from the Rio Sabinas, and 15 mi. N.E. of the Pacific port of Tonala. The former capital, San Cristobal (pop. 11,768), about 40 mi. E. of Tuxtla, is an interesting old town and the seat of the bishopric of Chiapas, founded 1525 and made famous through its associations with Las Casas. Tapachula (pop. 15,187), the capital of the department of Soconusco, 18 mi. from the Guatemalan frontier, is a commercial town of the coffee district. It is 24 mi. inland from the small port of San Benito, is 559 ft. above sea level and has a healthful climate.

CHIAROSCURO, the disposition of light and shade in painting (Ital. *chiaro,* light; *oscuro,* shade); the term is applied to an early method of printing woodcuts in various tones from several blocks, and also to a picture in black and white, brown and white only. It has also come to mean the atmospheric effect produced by the handling of high lights and shadows.

CHIAVARI, a town near the mouth of the Entella, Liguria, It., province of Genoa, 24 mi. S.E. by rail from Genoa. Pop. (1951) 20,324 (commune). It is in a fertile plain surrounded by mountains except on the southwest, where it comes down to the sea. It trades in farm products, and makes la

light wicker-seated bentwood chairs and silk.

CHIAVENNA (anc. *Clavenna*), a town of Lombardy, Italy, in the province of Sondrio, 17 mi. by rail north of Colico, which lies at the north end of the Lake of Como. Pop. (1936) 3,803 (town); 5,379 (commune). It is on the right bank of the Mera, at the mouth of the Val Bregaglia, through which the road to the Maloja pass and the Engadine runs to the east. This line was followed by a Roman road, which took the Julier route to Coire (anc. *Curia*). The Splügen route, also used by the Romans, runs north from Chiavenna to Coire: the modern road was constructed by the Austrians in 1819–21. Chiavenna's ruined castle was the seat of the counts who ruled the valley from the time of the Goths till 1194, when the district was handed over to the bishops of Coire. In the 14th century the Visconti, as masters of the Valtellina, bought the "county" of Chiavenna from the bishop of Coire; but it was taken by the canton of the Grisons in 1525, and the castle dismantled. In 1797 Chiavenna became part of the Cisalpine republic, and thenceforward followed the fortunes of Lombardy. Chiavenna has cotton factories and breweries, and is a depot for the wine of the district because of the coolness of the caves which are used as cellars.

CHIBCHAN, an important linguistic stock of South American and Central American Indians. The tribes to be included within this stock and its precise geographic limits are still open to discussion. Beginning with the Ulvan tribes along the Honduras-Nicaragua border southward and eastward through Nicaragua, Costa Rica and Panama, the larger proportion of all the tribes belonged to Chibchan stock. In Colombia they probably held most of the drainage basins of the Magdalena and Cauca rivers. The region of the Cordillera Central, between these streams, was, however, held by tribes classed as Paniquitan (*q.v.*), who are regarded by some as constituting a distinct stock. Rivet would include as Chibchan also the Barbacoan (*q.v.*) and Coconucan (*q.v.*) tribes farther south, extending as far as the equator in western Ecuador. There has been considerable difference of opinion as to whether the direction of movement of the stock has been southward into South America or from the southern continent into North America. The more recent opinion seems to favour the former view, but the question cannot by any means be regarded as settled. The stock has received its name from the Chibchas (*q.v.*), the most important tribe of the stock at the time of the Spanish conquest.

See H. Beuchat and P. Rivet, *Affinités des langues du sud de la Colombie et du nord de l'Equateur*, vol. xi (Museon, 1910); W. Lehmann, *Zentral Amerika* (Berlin, 1920).

CHIBCHAS, a small group of tribes of South American Indians, occupying at the time of the Spanish conquest the high valleys in the vicinity of Bogotá and Tunja in Colombia. In their culture the Chibchas and other related tribes in the vicinity ranked next to that developed by the Inca and their predecessors in Peru and Bolivia. They were, however, on a distinctly lower level, for although a sedentary, agricultural folk, skilful weavers and artificers in gold, they had little copper and no bronze. They were also much inferior in pottery making, had no knowledge of stone or sun-dried brick construction and had no means of record, such as the Peruvian quipu. Just prior to the advent of the Spanish, the Zipa, or chief, of the Chibchas at Bogotá had been successful in extending his political control over several of the tribes farther north, and seems to have initiated a movement which, but for the Spanish conquest, might have paralleled the military expansion of the Aztecs in Mexico. Like the latter, the Chibchas employed human sacrifice in their religious ceremonials. In one of these, the chief, or "king," was smeared with a sticky substance and then powdered with gold dust, which was subsequently washed off by bathing in a sacred lake. It was this practice which, at least in part, gave rise to the legend of "El Dorado." The dead were buried in well-graves, which sometimes attained a depth of 30 or 40 ft.

CHIBOUQUE or **CHIBOUK,** a long Turkish pipe (Fr. form of the Turk. *chibūk*, "a stick"), often ornamented with precious stones.

CHICA, an orange-red pigment or dyestuff obtained from the leaves of *Bignonia chica* by the Orinoco Indians.

CHICACOLE, a town of British India in the Ganjam district of Madras, situated on the right bank of the river Languliya, crossed there by a bridge, 4 mi. from the sea. Pop. (1941) 22,249. Under Mohammedan rule it was the capital of one of the Northern Circars, and afterward of a British district. Several old mosques remain.

The town was formerly famous for its muslins.

CHICAGO, a city, a port of entry and the county seat of Cook county, Ill., the second city of the United States in population, commerce and manufacture; pop. (1910) 2,185,283; (1920) 2,701,705; (1930) 3,376,438; (1940) 3,396,808; (1950) 3,606,436, an increase of 6.2% over 1940. The increase in the decade 1920–30, partly as a result of annexations, was 674,733, the largest gross gain in the history of the city.

The population of the metropolitan district of Chicago, embracing suburbs of the city both in Illinois and Indiana, but excluding adjacent communities in Wisconsin, was 5,475,535 in 1950, an increase of 14% over 1940. As is the case with most U.S. cities, the growth of the population of Chicago has decreased relatively to the growth of the outlying communities of its metropolitan area. The rate of regional growth about the city increased as the rate of strictly urban growth declined, largely because of the extension of motor traffic and hard-surfaced highways. The almost negligible increase of the population of the city of Chicago proper from 1930 to 1940 represented a net balance of gains in half the city's wards and losses in the other half.

Chicago is situated at the southwest corner of Lake Michigan (lat. 41° 50′ N., long. 87° 38′ W.), about 913 mi. distant by railway from New York city, 912 mi. from New Orleans, La., 2,265 mi. from Los Angeles, Calif., and 2,330 mi. from Seattle, Wash. The climate is very changeable and is much affected by the lake; changes of more than 30° in temperature within 24 hrs. are not rare, and changes of 20° are common. The city lies 598 ft. above sea level.

The greatest railway centre of the United States, Chicago for several decades was practically the only commercial outlet of the great agricultural region of the northern Mississippi valley. Trunk lines reach east to Montreal, Que., Boston, Mass., New York, Philadelphia, Pa., Baltimore, Md. (the nearest point on the Atlantic coast, 854 mi.); south to Charleston, S.C., Savannah, Ga., Florida, Mobile, Ala., New Orleans, Port Arthur, Tex., and Galveston, Tex.; west to the Pacific at Los Angeles, San Francisco, Calif., Seattle and Vancouver, Wash., and to most of these by a variety of routes. Thirty-two trunk lines operated by 22 railway companies enter the Chicago terminal district. In this terminal system about 4½% of the total freight tonnage of the United States is loaded and 6¼% unloaded annually. Chicago is also the greatest Canadian railway centre from a traffic standpoint.

The Canadian National lines and the Canadian Pacific enter it through subsidiaries.

The passenger-terminal situation, like the intramural rail-transit problem, was altered to fit the great city, which grew up around the original railheads and then passed miles beyond them. In 1911 the passenger station of the Chicago and North Western railway, a dignified structure costing $20,000,000, was opened for service. The railways using the Union station directly south of this terminal—the Pennsylvania, the Burlington, the Gulf Mobile and Ohio and the Milwaukee road—completed in 1925 their terminal at a cost of $75,000,000. With the construction of a great postal-terminal building near by, this completed the rearrangement of the terminals of the railroads on the west side of the Chicago river. But the far more numerous railways entering four passenger terminals on the south side spent years working out a plan for consolidation and rearrangement, still incomplete at mid-20th century. Decline of railway passenger traffic because of automotive and aerial competition and weakened railway finances during the depression of the 1930s diminished interest in these

projects. But the straightening of the Chicago river followed by the building of through streets through the area foreshadowed its better use. Building of industrial structures over railway tracks and lease of railway "air rights" began. The first railway electrification was completed July 21, 1926, when the Illinois Central railway opened its electrified suburban passenger service over the 30 mi. from Matteson, Ill., to Randolph street at a total cost of $40,000,000.

With its suburbs within the area of the Chicago railway-terminal district, Chicago occupies a crescent-shaped area, the concave side of which is the shore of Lake Michigan. This Chicago district is 1,719.29 sq.mi. in extent, about the size of Rhode Island, and lies along the lake shore for about 55 mi. (the incorporated city proper for 26.5 mi.). The city proper has a land area of 206.7 sq.mi. It spreads loosely and irregularly backward from the lake over a shallow alluvial basin, which is rimmed to the west by a low moraine water parting that separates the drainage of the lake from that of the Mississippi valley. The city site has been built up out of the Lake Chicago of glacial times, which exceeded in size Lake Michigan. Three lakes—Calumet, almost five square miles, Hyde and part of Wolf—with a water surface of about six and one-half square miles lie within the municipal limits. The original elevation of what is now the business heart of the city was only about seven feet above the lake, but the level was greatly raised—in some places more than ten feet—over a large area between 1855 and 1860. The west side, especially the northwest near Humboldt park, is much higher (highest point, 75 ft.). A narrow inlet from the lake, the Chicago river, runs west from its shore about a mile, dividing then into a north and south branch, which run respectively to the northwest and the southwest, thus cutting the city into three divisions known as the north, the west and the south sides. The river no longer empties into Lake Michigan since the completion of the drainage canal. Its commercial importance is still great; but with the change in the character of lake traffic it diminished, and this stream and harbour upon which Chicago's history and greatness were based are looked upon primarily as an obstruction to urban street traffic. Agitation for the abolition of the river as a shipway and for the substitution of fixed bridges for the draw, lift and bascule types became active. Ship traffic on the lake became principally a matter of the transport of bulk cargoes of iron ore, coal, coke and limestone direct from mine rail terminals to the great iron, steel and cement plants with their own docks on the south shore of Lake Michigan. Traffic shifted to the ports on the southern extremities of the city, Calumet Harbor, Indiana Harbor, etc.; and steamers formerly docking in the river call at the Navy pier or dock in the outer harbour. Some lake cargo destined for Chicago is landed at Milwaukee, Wis., and comes in by rail.

Upon the completion of the Illinois waterway, connecting Chicago, through the Illinois and Mississippi rivers, with New Orleans by a barge route of nine-foot draft, the Chicago river became an important link for through water traffic; but it was proposed to obviate this by widening a direct canal to connect the south lake harbour with the drainage canal to constitute a link of the waterway.

The improvement of the city's outer harbour by the federal government was begun in 1833. Great breakwaters protect the river mouth from the silting shore currents of the lake and afford secure shelter in an outer roadstead from its storms, and there is a smaller inner basin (about 450 ac., 16-ft. depth) as well. The river itself has about 15 mi. of navigable channel, in part lined with docks. Its channel was repeatedly deepened and, especially from 1896, after its control as a navigable stream passed (1890) to the federal government, widened and straightened by the removal of jutting building constructions along its shores. Grain elevators of enormous size, coalyards and warehouses once crowded close upon it. In 1927 the south bank of the river from the Michigan avenue bridge to Lake street, the northern boundary of the loop business district, was completely denuded of abutting buildings by the opening of the two-level Wacker drive, a broad boulevard upon a gigantic concrete structure occupying the space of former blocks of buildings and streets. This construction, which cost about $28,000,000, and which connects with the Michigan avenue bridge and the two-level boulevards approaching it, was the first item of a program designed to convert the entire south and east banks of the river into broad traffic arteries. Its extension southward from Lake street was begun in 1949. Farther south, under an agreement of the railways, property owners and the city, the south branch of the river, which curves to the east for about a mile of its length, was moved westward for a maximum distance of a quarter of a mile, to allow the construction of wide streets leading from the south into the loop district.

The plan of the city was originally regular (*i.e.*, rigidly rectangular) and the original streets were wide according to the standards of the days of horse-drawn traffic. The original plan was altered by the construction of a great number of boulevards in the outer areas which, in connection with the growth of the park system and the construction of driveways in the parks, provided numbers of diagonal traffic arteries. The recovery of land from the lake and the construction of a great parkway system along the lake front also led to the belting of the downtown areas on the east with a number of north and south boulevards not in keeping with the original plan of the city. The initiation and completion of these projects were so rapid and the number of new plans in various stages of execution so great that the older parts of Chicago were profoundly altered, especially during the great building boom of 1922–28.

Rapid transit by rail did not keep pace with these improvements in streets. One result was that a number of outlying business, hotel and apartment centres grew up, which began in the aggregate to rival the loop, the former business, financial, theatrical and hotel centre. Chicago developed into a series of urban centres rather than a centralized city on the usual U.S. model. Notwithstanding the growth of these outlying centres, however, the construction of great buildings within the loop from 1922 to 1928 proceeded at a pace never approached before, while the opening of Wacker drive and the Michigan avenue bridge enabled the business district to break out of the narrow confines of the former loop district—the one and one-half square miles lying between the lake, the main Chicago river and the south branch of the river. This northward advance of the business district was accompanied by the construction of numbers of the tower type of office building. This forest of bold and graceful towers relieved the former drab monotony of downtown Chicago. The construction of so many great office buildings and hotels in the downtown district made the problem of street congestion increasingly acute despite the enormous expenditures upon new boulevards. Hope for any material relief from the construction of the freight tunnels vanished with the advent of the popular-priced automobile, and the capacity of these underground freight arteries is such that they can handle only a trifling percentage of the movement of goods in the district. A belt of "badlands"—deteriorated residence, shop and factory property—surrounds the business district except on the northeast. There a great section crowded with expensive family and apartment hotels grew up on the lands reclaimed from the lake in the section called "Streeterville"—named from a belligerent old squatter who long claimed title to these accretions because his schooner had stranded on that shore. Chicago's architectural achievements are yet blighted by the use of soft coal, which after a time smears a drab colour on the finest structures. Vigorous efforts to combat this nuisance have had small results. Yet the sky line, the immensity of the traffic movement and the massiveness of its central district give the city a distinct tone, found nowhere else.

The unstable soil of sand, clay and boulders that underlies the city is unfavourable to tall constructions, and necessitates extraordinary attention to foundations. The bedrock lies, on an average, 50 ft. below the level of the lake (in places more than 100). The foundations are often sunk to the rock in caissons, the buildings resting on monster columns of concrete and steel. In other cases great "pads" of the same materials, resting or "floating" upon the clay, sustain and distribute the weight of the building.

Buildings notable for their architectural boldness and the

beauty which resulted from the conversion of the economics of the tall structure to aesthetic purposes are the Chicago temple, a spire above an office pile, the Tribune tower, distinguished for its flying buttresses, the Wrigley building with its campanile tower and the Civic Opera building, which faces across the river the Daily News building and plaza. A large part of the business of the former dry goods wholesale district is housed in the huge Merchandise Mart on the north bank of the river.

The Board of Trade building topped by a statue of Ceres poised 612 ft. in the air is at the south end of the financial district of LaSalle street.

Older buildings associated with the city's history or notable architectural triumphs of their day are the Auditorium—now occupied by Roosevelt college—the Continental Illinois bank, the Monadnock, the People's Gas building, the LaSalle, Blackstone and Sherman hotels and the Marquette building. There are a number of enormous retail stores. The largest, and one of the finest in the world, is that of Marshall Field and Co.

The city hall and county building (cost $8,617,626) is an enormous double structure in a free French Renaissance style, with columned façades.

The federal building (finished in 1905; cost $4,750,000) is a massive edifice (a low rectangle surmounted by a higher inner cross and crowned with a dome). The public library (1893–97, $2,125,000) is constructed of dark granite and limestone, with rich interior decorations of varied frescoes, mosaics, ornamental bronze and iron work and mottoes. The Art Institute of Chicago, Orchestra hall and the Museum of Science and Industry are also noteworthy. The Chicago Natural History museum, completed in 1920 at a cost of $6,000,000, is a white marble structure in Ionic style, 350 ft. wide and 700 ft. long.

Navy pier, completed in 1915, projects 3,000 ft. into Lake Michigan, north of the mouth of the Chicago river and combines the functions of an enormous dock, a school (University of Illinois's Chicago undergraduate division) and a playground. It has two exhibition halls, each one-half mile in length, one of which has the largest unobstructed floor space of any exhibit hall in the United States. The movement of wealthier residents to surrounding communities left the city proper without any notable street of private homes, although many of the older boulevards are fringed by dignified houses. The physical growth of Chicago after 1909 was guided by a definite plan laid down by the Chicago Plan commission, created by the city council during the administration of Mayor Fred A. Busse. The plan had its genesis in a report of Daniel H. Burnham and was submitted by the Commercial club to the city and adopted as an enduring policy. It took cognizance of the natural features of Chicago's site and environs and proposed the gradual adaptation of the city then existing, and the city as it grew, to the best uses of its natural setting—from a commercial, industrial, social and cultural standpoint. The plan was constantly modified and expanded to keep pace with new conditions and problems. Railroads, public utility companies and industrialists co-operated to carry out its designs. The Chicago plan demonstrated that the most intensive modern industrialism and commercial activity can be profitably harmonized with beauty, social welfare and ample recreational and cultural centres for the people of a metropolitan city.

Public Works and Communications.—Local transit is provided for by suburban railway service, motorbuses, elevated electric roads and a system of electric surface cars. Two great public works demand notice: the water system and the drainage canal. Water is pumped from Lake Michigan through several tunnels connecting with cribs located from two to five miles from shore. The cribs are heavy structures of timber and iron loaded with stone and enclosing the intake cylinders, which join with the tunnels well below the bottom of the lake. The first tunnel was completed in 1867. The tunnels form a 100-mi. labyrinth under the lake and city. The average amount of water pumped per day at mid-20th century was 971,000,000 gal. Because of pollution of lake water from the wastes of Indiana cities, not participating in the drainage system of the Chicago sanitary district, this water has been chlorinated at the intakes. The wastes of the city—street washings, building sewage, the offal of slaughterhouses and wastes of distilleries and rendering houses—were originally turned into the lake, but before 1870 it was discovered that the range of impurity extended a mile into the lake, halfway to the water crib; and it became evident that the lake could not be indefinitely contaminated. The Illinois and Michigan canal was once thought to have solved the difficulty. It connected with the main (southern) branch of the Chicago river, five miles from its mouth, and with the Illinois river at La Salle, and was the natural successor in the evolution of transportation of the old Chicago portage, one-half mile in length, between the Chicago river and the headwaters of the Kankakee. It was so deepened as to draw water out from the lake, whose waters thus flowed toward the Gulf of Mexico; but it proved inadequate for the disposal of sewage. A solution of the problem was imperative by 1876, but almost all the wastes of the city continued nevertheless to be poured into the lake. In 1890 a sanitary district, including part of the city and certain suburban areas to be affected, was organized, and preparations made for building a greater canal that should do effectively the work it was once thought the old canal could do. The new drainage canal, one of the greatest sanitary works of the world, constructed between 1892 and 1900 under the control of the trustees of the sanitary district of Chicago, joins the south branch of the Chicago with the Des Plaines river, and so with the Illinois and Mississippi. The canal, or sewer, is flushed with water from Lake Michigan, and its waters are pure within a flow of 150 mi. Its capacity, which was not at first fully utilized, is 600,000 cu.ft. per minute, sufficient to renew entirely the water of the Chicago river daily. A system of intercepting sewers to withdraw drainage from the lake was begun in 1898; and the construction of a canal to drain the Calumet region was begun in 1910. This system was later changed and extended to deliver all sewage to plants for oxidation and chemical treatment. The drainage canal is the backbone of a great system of feed-water lateral canals and underground sewers. The drainage canal became the nucleus of the Lakes to the Gulf waterway, under construction by the state of Illinois to connect the drainage canal with the Illinois river, the federal government undertaking the improvement of the rivers to the gulf. The canal also made possible the development at Lockport of hydroelectric power, which is used by the sanitary district and for street lighting in Chicago.

The lowering of lake levels which resulted brought protests and litigation from other lake cities. Shipping interests blamed the drainage canal for the lower levels and the shoaling of port and dock channels. The sanitary district denied responsibility for more than six inches of the fall in the levels of Lakes Michigan, Huron and Erie, and offered to construct compensating weirs to retain levels in the St. Clair river, connecting Lakes Huron and Erie, and in the Niagara river. Litigation against the sanitary district by the other lake states was defended in the United States supreme court by the state of Illinois, assisted by other states of the Mississippi valley interested in maintaining the diversion of lake water into the Mississippi drainage system in aid of navigation.

The first adverse decision by the supreme court was handed down Jan. 5, 1925. Finally, that tribunal decreed that the diversion of water should be reduced to 1,500 cu.ft. per second by 1938. The sanitary district was given time to construct sewage purification works, but its extravagance and depleted resources would have made that impossible had it not been for the aid of the federal treasury extended as grants to relieve unemployment. The works prior to 1950 cost $262,000,000.

Chicago was early a centre of aerial transport. The first municipal airport was established in 1927 and by mid-century the three city-owned airports were handling more than 3,250,000 air passengers annually. Plane arrivals and departures at the Midway (Municipal) airport averaged more than 600 daily. Twelve major air lines provided 450 regularly scheduled trips per day. In addition, many other lines provided air-freight and air-express services.

Atrophy of the city's internal traction and elevated systems after 1907 was partially compensated for by the establishment of numerous motorbus lines on the boulevards and parkways, and by

the extension and modernization of electric railways in the outlying regions. Numerous bus lines connecting Chicago with other towns and cities came into competition with the railways. Another great improvement was begun in 1901 by a private telephone company. This is an elaborate system of freight subways, more than 62 mi. of which, underlying the entire business district, had been constructed before 1909. It is the only subway system in the world that seeks to clear the streets by the lessening of trucking, in place of devoting itself to the transportation of passengers. Direct connection is made with the freight stations of all railways and the basements of important business buildings, and coal, building materials, ashes and garbage, railway luggage, heavy mail and other kinds of heavy freight are removed and delivered. Telegraph and telephone wires are carried through the tunnel, and can be readily repaired. The subway was opened for partial operation in 1905. However, street traffic growth was so great and the capacity of the tunnels so small, that the 125 locomotives and 2,500 cars operated in the tunnels at mid-century were handling less than 10% of railway freight loaded or unloaded in the business district.

Parks.—The park system may be said to have been begun in 1869, and in 1870 aggregated 1,887 ac. Chicago then acquired the name of the "Garden City," still emblazoned on the municipal coat of arms. But other cities later passed it, and in 1904 Chicago ranked only 32nd among U.S. cities of more than 100,000 population in per capita holdings of park acreage. The area of the city's parks is 7,327 ac., but this was extended all along the lake front by the reclamation of land from the lake for parks, bathing beaches and an island airport (Meigs field) near the business district.

In addition to the city park system, the Cook county forest preserves, a broad belt of wooded lands, 38,000 ac. in extent, acquired over many years, form a belt north, south and west of the city. The value of this great playground is attested by a census of visitors for one year which totalled 5,500,000. In the same year 4,582,000 persons bathed at the city's supervised bathing beaches and 3,700,000 children were counted at the city's playgrounds. The large and small parks number 300. There are 71 bathing beaches and public pools, 25 free public golf courses and 98 public playgrounds. The park in each district, usually located near a school, is almost all-inclusive in its provision for all comers, from babyhood to maturity, and is open all day.

The older parks include several of great size and beauty. Lincoln park, near the lake shore of the north side, was much enlarged by an addition reclaimed from the lake. It has fine monuments, conservatories, a zoological garden and the collections of the Academy of Sciences. Jackson park, on the lake shore of the south side, was the main site of the World's Columbian exposition of 1893. It is joined with Washington park by the Midway Plaisance, a wide boulevard. Along the Midway are the buildings of The University of Chicago. On the west side of the city are three large parks—Douglas, Garfield (with a fine conservatory) and Humboldt, which has a remarkable rose garden—and in the extreme south side several others, including Calumet, by the lake side, and Marquette. The shore of the north side is quite free, and beginning a short distance above the river is skirted for almost 30 mi. by Lake Shore drive and Sheridan road. In Grant park is the building of the Art institute, the Shedd aquarium, the Adler planetarium, the Chicago Natural History museum and Soldier Field, a great stadium devoted to sports and pageants, with a capacity of about 200,000. About two-thirds of the city's frontage on the lake is composed of parks or boulevards. The inner boulevards and the drives through the lake-front parks are parked ways ranging from 150 to 300 ft. in width. (L. H. L.; X.)

Art and Music.—The history of Chicago as an art and music centre has been impressive. The city has produced important composers, headed by John Alden Carpenter; painters like G. P. A. Healy and Oliver Dennett Grover; and sculptors like Lorado Taft. Its Art Institute of Chicago is outstanding among the great world museums in its collections of 19th- and 20th-century paintings. The Symphony orchestra is one of the four or five great U.S. orchestras. Its Civic Opera house, built in 1929 by Samuel Insull, is the best equipped scenically in the Americas or Europe. Chicago opera, under the regime of Mary Garden and with the financial backing of Mrs. Rockefeller McCormick challenged the supremacy of New York's Metropolitan during the second decade of the 20th century. With the crumbling of the Insull financial empire and the financial depression of the 1930s, however, opera sank to a low ebb.

Art started in Chicago in 1855 when an Irish carpenter, Martin O'Brien, set aside a small corner of his shop for the framing of Currier & Ives prints, and later for the sale of prints and paintings. On April 13, 1861, O'Brien opened an adjoining shop devoted exclusively to his growing picture business. It became the favourite meeting place of G. P. A. Healy, back from Europe, where he had painted European aristocracy and royalty. In 1866 O'Brien's customers and others formed an association for the purpose of studying art history and methods, "copying in oil" the paintings in the establishment and even posing models. They rented rooms in a neighbouring building, called themselves the Chicago Academy of Design, and were beginning to flourish when the Chicago fire of 1871 put an end to their activities.

The club was kept loosely intact, and in 1878 started again, this time incorporating as the Chicago Academy of Fine Arts, and electing as president George Armour. In 1882 the academy changed its name to the Art Institute of Chicago, reorganized and elected a new president, Charles L. Hutchinson. Under Hutchinson's administration, which continued to 1924, the institute built its museum and school on the lake front, and assembled under its roof the collections of the Potter Palmers, the Logans, Nickersons, Ayers, Buckinghams, Butlers, Leiters, Ryersons and Hutchinsons. On loan in the museum in 1924, too, was the Birch-Bartlett collection, to be accepted later as a gift, the first great collection of the European moderns in a U.S. public museum.

The Art Institute of Chicago remained the centre of the city's art activities, more intimately than in any of the great capitals of the world. New York city, London, Paris, Rome and other large cities all have two or three or more public galleries, rivalling each other in importance. The Arts Club of Chicago, which opened the day the Armistice was signed in 1918, was for a time a rival, bringing to Chicago the art of the 20th-century European moderns. But the Art institute, accepting slowly and steadily the innovators, finally absorbed the function of the Arts club. Numerous commercial galleries, starting with O'Brien's pioneer shop, and numerous art organizations were established and flourished in Chicago and its suburbs.

The musical history of Chicago starts even earlier than its art history. There were enough people on the mud flats along Lake Michigan as early as 1850 to encourage a music teacher, John Dyrenfurth, to found a philharmonic society with himself as conductor. In 1854 Dyrenfurth encouraged a concert troupe to visit Chicago. Theodore Thomas was first violinist. Three years later the Mendelssohn Singing society was organized by George P. Upton. This society later became the Apollo Musical club, still in existence at mid-20th century. In 1869 Thomas visited the town again, this time as conductor of a travelling orchestra of 40 pieces. He booked another concert for Oct. 9, 1871, but the Chicago fire intervened. After the fire he returned repeatedly with his orchestra, and eventually, in 1891, he came to stay. He organized a local orchestra, which he called the Chicago Symphony orchestra. In 1904 he and his orchestra moved into the new Orchestra hall, across the street from the Art Institute of Chicago, and there it remained. Thomas himself promoted the building of the hall, with a long list of subscribers donating. Thomas conducted the orchestra until his death in 1905 and was succeeded by Frederick Stock (1872–1942).

Meanwhile, the Auditorium was built to house opera, which had made its Chicago debut July 30, 1850, in Rice's theatre. Before the second act was over, fire broke out, and it was several years before Chicagoans were to see the finish of the opera *La Sonnambula*. A more substantial *première* was staged on April 20, 1865, when the Grau Grand Opera company sang *Il Trovator* This *première* was a delayed performance, having been scheduled for April 17, but postponed because of the assassination of Abraham Lincoln in Washington, D.C.

The Auditorium was dedicated Dec. 9, 1889, with Pres. Benjamin Harrison as guest of honour and Adelina Patti singing with the Apollo club. The next night, Patti and the Grau Grand Opera company sang *Romeo and Juliet*, and opera was an established institution in Chicago. The city depended on the Grau company and other touring organizations, including the Metropolitan and the Manhattan companies until 1910, when it organized its own opera, with leading citizens contributing. This Chicago Opera company brought in Mary Garden eventually, not only as a prima donna but as an artistic manager, and started a real rivalry with the Metropolitan of New York city.

Numerous minor orchestras and opera companies also were established in Chicago, along with scores of singing societies, notably the Paulist choir. During the depression of the 1930s, the city of Chicago and the Works Progress administration presented open-air symphony concerts in Grant park to crowds which on some nights numbered 500,000 people. Both the opera and the symphony organizations also went into the open air in Ravinia park, 25 mi. N. of Chicago, for performances rivalling those presented downtown in the regular seasons. (C. J. Bt.)

Libraries.—At the head of the libraries of the city stands the public library, established in 1872, the nucleus of which was a collection of books from England, Ireland, Germany, France and other countries, after the great Chicago fire of 1871, a collection to which many contemporary literary and other celebrities made contributions. The library was opened in 1874. The main library in 1950 had 2,196,742 vol., in addition to independent collections ranging from 5,000 to 50,000 in 34 general branches, 15 branch library buildings and 27 subbranches.

The circulation of books in 1949, in addition to those used on the main shelves of the central library, was 8,719,880. The John Crerar library, endowed in 1889 by John Crerar, wealthy manufacturer of railway supplies, had in 1950, about 700,000 vol. on social, physical, natural and medical sciences and their applications. It occupies a large building across the street from the main building of the public library at Randolph street and Michigan avenue. The Newberry library, endowed by a bequest of Walter L. Newberry, in 1950 contained 650,000 vol., chiefly in the field of the humanities, history and literature. These three libraries cooperate to avoid useless duplication and each has certain special fields. Other important collections are the library of The University of Chicago; the Burnham Library of Architecture and the Ryerson library in the Art institute, devoted to fine arts and travel; the libraries of Northwestern university (including the Elbert H. Gary law library), the Chicago Natural History museum, the Museum of Science and Industry, the Illinois Institute of Technology, Loyola university, Garrett Biblical institute; the Virginia collection of the McCormick Historical Association library; and the Municipal Reference library, containing a great collection of documents and data on municipal government in Chicago and elsewhere. Many trade, engineering and professional organizations maintain special libraries at their national or sectional headquarters in Chicago.

Universities and Colleges.—The leading university is The University of Chicago (*see* Chicago, The University of). The professional departments of Northwestern university are mostly located in Chicago while the academic and theological departments are in the suburb of Evanston. Northwestern university was organized in 1851 by the Methodist Episcopal Church and retained nominal relations with the denomination. In 1950–51 it had a student enrolment of 20,196 with 1,848 instructors. Loyola university, with a beautiful 25-ac. campus, De Paul university and Mundelein college for women are the principal Catholic schools of the city. Other schools of importance are: Illinois Institute of Technology, George Williams college, North Park college, Roosevelt college, occupying the former Auditorium building on Michigan avenue, three public junior colleges and the Chicago Teachers' college of the city's board of education. The University of Illinois, at Champaign-Urbana, maintains an undergraduate division at Chicago, as well as its professional colleges of medicine, dentistry and pharmacy. Theological schools independent of the universities include the Presbyterian Theological seminary, the Chicago Theological seminary (Congregational, opened 1858, and including German, Danish-Norwegian and Swedish institutes), the Seabury-Western Theological seminary at Evanston, a German Lutheran theological seminary and an Evangelical Lutheran theological seminary. There are a number of independent medical schools and schools of dentistry and veterinary surgery.

Newspapers.—The morning newspapers published in English are the *Tribune* and the *Sun-Times* (tabloid), established as the *Sun* in 1941 and merged with the *Times* in 1947.

The afternoon papers are the *Daily News*, the *Herald-American* and the *Sun-Times*. The last two publish an edition Sunday mornings, as does the *Tribune*. Formerly supporting more than a dozen dailies, many of pronounced partisan affiliations, the city of Chicago has no daily newspapers that have other than nominal political-party connections. In the number of publications, though not in circulation, the foreign-language press outstrips the English publications—foreign-language dailies including publications in Polish, Yiddish, German, Swedish, Czech, Greek and Italian. The city is the largest U.S. printing centre in point of volume of output, and many trade, labour, scientific and religious publications are included in its total of approximately 800 periodicals. In 1920 the city's first financial daily, the *Chicago Journal of Commerce*, was established. The Joseph Medill school of journalism, named after the founder of the *Chicago Tribune*, was opened as a part of Northwestern university in 1921, the *Tribune* underwriting any deficits for a period of years.

Industry and Commerce.—Chicago's situation at the head of the most southwestern of the Great Lakes has given it great importance in trade and industry. The growth of its trade has been enormous. After the beginning of the 20th century, however, Chicago underwent an industrial and commercial transformation roughly parallel to that of the U.S. as a whole. The city's paramount position as a great market in the 19th century was associated with the extractive industry of the U.S. economy of that day, and Chicago's trade consisted principally in the assembly and distribution of the raw crops and resources of fields and forests; its industries were mainly processing raw products, such as meat packing, woodworking, flour milling, tanning, etc. While these great industries remained important, Chicago's leading position in regard to them, except in meat packing, disappeared, but this was made up many times by the growth of an intensive industrialism. The city made great strides as a centre of the iron and steel industry, including many other products such as cement. The Calumet steel and iron region south of the city made tremendous progress after the founding of the steel city of Gary in 1906 just across the Indiana state boundary, and in manufacturing plants for heavy iron and steel products the Chicago region came to stand to the Pittsburgh, Pa., district—U.S. leading steel region—in the ratio of 10 to 13, while the operations became more continuous in the Chicago district.

The last years of the 19th century showed, however, an inevitable loss to Chicago in the growth of Duluth, Minn., Kansas City, Mo., and other rivals in strategic situations. In particular, the struggle of the north and south railway lines in the Mississippi valley to divert grain and other freight to ports on the Gulf of Mexico caused great losses to Chicago. An enormous increase in the cereal trade of Philadelphia, Baltimore, Newport News, Va., and Norfolk, Va., was partly because of the traffic eastward over lines south of Chicago. The traffic of the routes through Duluth and Canada did not, indeed, represent actual losses, for the traffic was largely a new growth; but there was nevertheless a considerable drain to these routes from U.S. territory which was once tributary to Chicago. Altogether the competition of the Gulf roads and the lines running southwest from Duluth had largely excluded Chicago by 1899 (according to its board of trade) from the grain trade west of the Missouri river; its facilities for receiving and distributing remained nevertheless unequalled, and it continued practically to monopolize the traffic between the northern Atlantic seaboard and the central west. The city's position as a gateway for passing trade is indicated by the fact that one-eighth of the traffic of its railway terminals is through traffic.

New York alone among U.S. cities has a greater trade. Chi-

cago is the greatest railway centre, the greatest grain market, the greatest livestock market and meat-packing centre in the world and holds world primacy in a large number of smaller manufacturing industries.

Chicago has never participated to a great extent in international finance. The collapse of the speculative boom of 1929 and the bankruptcy of the Insull utility investment corporations checked a promising growth of domestic finance and investment banking.

Annual bank clearings for 1949 totalled $35,806,000,000, more than double the clearings of 1940. In April 1949 Chicago banks had loans and discounts of $1,944,756,000, deposits of $8,617,358,000, cash resources of $2,263,468,000 and savings deposits of $1,755,152,000.

The city's wholesale trade was estimated in 1875 at $293,900,000. In dollar value it reached a peak of $5,870,166,410 net sales disclosed by the census of distribution for 1929. In the ensuing depression money value declined greatly, physical volume to a lesser extent. The retail trade of the city reported by the census of 1949 amounted to $4,270,000,000 in net sales, the wholesale trade to $13,500,000,000. The Chicago board of trade remains the greatest speculative grain market in the world.

The grain elevators are still among the sights of Chicago. They are enormous storehouses into which the grain is elevated from ships and cars, sorted into grades and reloaded for shipment, all the work being done by machinery. Chicago's direct foreign trade is mostly by rail through other ports, although vessels of less than 14-ft. draught come in from the Atlantic on special trade voyages.

The Chicago industrial district, comprising the counties of Cook, Du Page, Kane, Will and Lake in Illinois and Lake in Indiana is the second largest in the United States. In 1950 the district had 10,500 manufacturing establishments, 1,000,000 factory wage earners and produced goods valued at $11,000,000,000. In 1937, during economic depression, the number of establishments was only 9,019. The number of wage earners was 538,775 and the value of goods produced was $4,711,428,323. As many as 192,000 families were on public relief rolls in Cook county at one time during the depression, at a monthly expense of $6,063,207.

The value added by manufacture in the Chicago metropolitan area of the following products in 1947 included: food and kindred products $714,614,000; textile-mill products $38,037,000; apparel and related products $222,905,000; lumber and products, except furniture, $35,144,000; furniture and fixtures $116,893,000; paper and allied products $122,656,000; printing and publishing industries $498,878,000; chemicals and allied products $385,123,000; petroleum and coal products $181,044,000; primary metal industries $678,036,000; fabricated metal products $495,435,000; machinery, except electrical, $700,787,000; electrical machinery $624,389,000; transportation equipment $236,237,000; instruments and related products $123,221,000; and miscellaneous manufactures $172,746,000. The International Harvester company, successor to the McCormick Harvester company, is the largest manufacturer of agricultural machinery in the world and the Western Electric company holds the same position in the manufacture of telephone equipment. The Pullman company manufactures railway freight and passenger cars. Meat packing, for which Chicago is best known, is the greatest local industry. In the enormous stockyards (about 500 ac. in area) from two-thirds to four-fifths of the cattle and hogs received are killed and sent out in various forms of prepared meats and by-products (lard, fertilizers, glue, butterine, soap, etc.). About 2,525,000 people (32% women) were gainfully employed in the Chicago metropolitan area at mid-20th century. This compared with 1,880,000 employed in 1939. Manufacturing accounted for 43% of the total; wholesale and retail trade 21%; service establishments 12%; transportation, communication and public utilities 9%; finance 5%; and miscellaneous 10%.

Public Utilities.—The development of manufacturing in Chicago went hand in hand with an equally remarkable development of public utility services, without which Chicago's industrialism would be impossible, for much of its factory industry is due to an abundance of cheap electric power, supplied by a highly efficient system of interconnected generating stations. The electrical output was 5,574,961,000 kw.hr. in 1929; in 1949, 11,987,651,000 kw.hr. There were 1,595,000 consumers of electric light and power in Chicago in the latter year. The company serving the incorporated city consumed about 9,035,918 tons of coal annually and for condensing purposes alone pumped an average of 1,978,000,000 gal. of water per day, more than the daily pumpage of the city water works. The local gas industry served more than 900,000 consumers within the incorporated city and is interconnected by pipe lines with the natural gas fields of Texas and with producing plants and consumers within a wide radius of the city. It makes use of surplus by-product gases generated in the steel and iron industry. Telephonic communication is in almost universal use by householders and by mid-century the work of converting the telephone system to the automatic switching type was virtually complete.

Administration.—Chicago is governed under a general city charter law of Illinois of 1872, accepted by the city in 1876, but the charter has been amended in some minor particular at every biennial session of the Illinois state legislature since that date. The essential framework of government, however, remains as it was originally adopted, and the efforts of municipal reformers to institute a complete new system of local government have been defeated, even when submitted to a referendum of the voters. Although the government remains apparently archaic and highly complicated, it really works about as well as that of the average U.S. municipality, and the faults of municipal government and politics in Chicago relate rather to the polyglot character of the population than to the form of government. Chicago remains a good example of the councilmanic form of municipal government, once almost universal in the U.S., but the legal and *de facto* powers and influence of the mayor have grown, even as the power of the presidential office has grown at the expense of congressional prestige and effectiveness in the federal government. A common council consisting of one alderman from each of the 50 wards is elected quadrennially. It controls the budget, police, excise, city contracts and franchises. The latter are subject to popular referendum, however. The council confirms appointments by the mayor and may pass legislation by a two-thirds vote, in spite of his veto. The mayor, selected every four years, is the executive head of the city. He appoints a cabinet, consisting of the heads of city departments, but most city employees are under a civil service law and are removable only under processes and tribunals provided by that law. There are several commissions in charge of city functions—such as the school board, the public-library board, the commission in charge of elections and that in charge of the Municipal Tuberculosis sanitarium. Administration of several pension funds for city employees is also committed to a number of commissions.

Like most U.S. cities Chicago has a dual city and county government. Cook county, which contains Chicago, retains practically all of the extensive government functions of rural counties of the type which arose in Virginia and the southern colonies, and in which the county was the real unit of local government. This complication of dual government in Cook county extends to the suburbs of Chicago, which have separate municipal organizations, while the county itself was laid out after 1848 in townships, somewhat on the New England town model. It was not until 1900 that the town organizations within the territory gradually annexed to the original village of Chicago were deprived of their political structure and divested of governmental functions within the city, and as late as 1903 ten townships exercised taxing power within the municipal area. A plan for the consolidation of local government was rejected by the people in 1920. In addition to the original duplications of government, new quasi-governmental bodies were set up for special purposes and in some cases were granted police and tax powers.

There are more than 400 distinct political units in Cook county, empowered to levy 600 different sorts of taxes. The average citizen of Chicago is under the jurisdiction of or in contact with 25 different kinds of governments. But in 1934 the voters approved the consolidation of 22 formerly independent park districts, and

these great properties with annual budgets of many millions passed under a board of five appointed by the mayor. Formerly they were a species of independent principalities within the city. Officials of some were appointed by the governor of Illinois, some were elected by the judges of the courts, some by the voters of the districts. They had powers of police, taxation and debt incurment.

In 1906 the archaic system of administering petty justice through the justices of the peace was abolished and a co-ordinated municipal court with numerous judges and a chief justice was established. The juridical system is complicated by the fact that the circuit court is a constitutionally established court of the state of Illinois. The superior, municipal and other special courts are created by statute. The sanitary district, practically an independent government in itself, with powers of tax levy and debt making, is superimposed over the territory of Chicago and Cook county. Both the state of Illinois and the federal government also extended the legislative and administrative regulation of industry and commerce, and maintain large staffs of officials in Chicago. The school board has been nominally separate from and almost independent of the city government in its powers since 1857. The forest preserves adjacent to the city's boundaries are also quasi-governmental bodies exercising some sovereign powers.

The initiative and referendum in local matters have been made possible by the state, and this power has been frequently exercised. Increases of the public debt are subject to popular vote, but financial arrangements under such a complex system of government are naturally loose and inefficient, co-ordinated budgeting being virtually impossible. The grant of independent taxing power to so many governmental bodies, in the Chicago area, as elsewhere in the U.S., is one result of state constitutional limitations upon the public debt. Chicago, as a municipal corporation, is prohibited from incurring debt in excess of 5% of the value of the property within the city. The inevitable result of such a restriction, whenever a great public necessity arose, was the creation of another taxing body not limited by pre-existing debt limits covering a given territory, within the jurisdiction of an existing governmental body.

Finances.—The budget for the city of Chicago proper for 1950 called for the expenditure of $188,236,912, including $26,398,855 by the water department, $6,110,000 by the Municipal Tuberculosis sanitarium, $5,215,000 by the public library board, $3,529,000 by the board in charge of firemen's pensions, $4,400,000 by the board administering police pensions and $7,360,000 by the board in charge of pensions for other municipal employees. Other funds in the budget out of which a variety of expenses are met, such as police, fire department and street and bridge maintenance, are the corporate fund of $81,329,663 and the debt service funds, amounting to $17,150,935. The separate school-board budget totalled $129,217,692; the park budget, $19,188,718; county budget, $37,346,365. In 1935 Chicago's revenues were disorganized and sadly deficient as the result of the worst financial crisis in the city's history. The full effect of the economic depression of 1929 struck the city in the midst of a general reassessment of real property to adjust gross inequalities of tax burdens. Taxpayers refused or were unable to pay their taxes. Forty-one per cent of taxes due were delinquent in 1933. Teachers and other public employees went for months without pay. Subventions from the federal government in the form of relief allotments and make-work grants helped the city tide over its crisis while rigid retrenchments were instituted. During the crisis the city sold tax-anticipation warrants and practically lived on future revenues, the collection of much of which was dubious.

Transit Problems.—Chicago's conspicuous failure as a city has been in the lack of providing adequate rapid-transit facilities.

At the mayor's election in 1905 the successful political party stood for municipal acquisition of all roads. Meanwhile, under the State Referendum act, the city in 1902 voted overwhelmingly for municipal ownership and operation (142,826 to 27,990); the legislature in 1903 by the Meuller law gave the city the requisite powers; the people accepted the law, again declared for municipal ownership, for temporary compulsion of adequate service and against granting any franchise to any company, by four additional votes similarly conclusive. At last, after tedious negotiations, a definite agreement was reached in 1906 assuring an early acquisition of all roads by the city. The issue of bonds for municipal railways was, however, declared unconstitutional that year. At the municipal elections of 1907 there was a complete reversal of policy; a large majority voted this time against municipal ownership in favour of leaving the working of the street railways in private hands and strengthening the powers of municipal control. For 20 years after 1907 the surface-car lines of Chicago were operated under unified management and rendered excellent service. The system was completely rebuilt, and that work led to the repaving of the city, so that the coming of the automobile age found Chicago comparatively well-equipped for motor transport. But with the growth of the city and the congestion of the streets by motor traffic, transportation by surface electric railways became too slow to meet the demands of the population. In the meantime, the construction of elevated railway lines practically ceased, except for extensions outside the incorporated city limits where the political factor did not enter into calculations. But construction of a subway did not begin until Dec. 17, 1938, when boring of 8.75 mi. of tube 40 to 50 ft. under State, Dearborn, Lake and other streets was begun. In two years the tubes were virtually completed to their connections with the elevated system outside the congested districts, but construction of stations and equipment remained to be done. Money from the city's accumulated traction fund was supplemented by a grant from the Federal Public Works administration to defray the cost of the project. The first unit —about four and three-fourths miles, mostly under State street— began operation in Oct. 1944. The second unit—the Milwaukee-Dearborn, about four miles—was opened in 1951.

Under the franchise arrangement of 1907 the city received 55% of the divisible net receipts of the surface lines—after payment of 5% on agreed capital, which with interest earned on the fund amounted to $47,518,060.66 Jan. 31, 1947. The city also has power to subject adjacent property to special assessments in aid of subway construction. When the 1907 franchise expired in 1927, no agreement was reached.

The lines were operated under temporary agreements pending an adjustment of the conflicting claims and proposals.

The Chicago Transit authority (C.T.A.) was created by act of the Illinois legislature, known as the Metropolitan Transit Authority act, approved April 12, 1945. By reason of this act, and proper municipal legislation, the C.T.A. on Sept. 30, 1947, acquired the properties of the Chicago surface and elevated railway lines. The authority functions as a semipublic body, publicly owned but privately financed to the extent of $105,000,000 through the sale of bonds to private investors. It acquired an exclusive 50-year franchise from the city.

The administrative agency of the C.T.A. is the Chicago Transit board, politically independent, and consisting of seven members who establish C.T.A. policy. The top operating officer of the system is the general manager.

The C.T.A. lines at mid-20th century comprised one of the largest local transit systems in the world, operating gasoline, diesel and trolley buses, streetcars, elevated and subway trains. C.T.A.'s operating territory included Chicago and 85 other municipalities in Cook county. Surface operations included 805.52 mi. of streetcar routes, 540.64 mi. of diesel and gasoline-bus lines and 59.34 mi. of trolley-bus lines. In 1949, 724,851,315 passengers were carried on these lines.

The rapid-transit operations embraced 77.22 route mi. of elevated railroad and 4.9 route mi. of subway lines; 161,570,270 passengers were carried in 1949. Motorbuses carried 100,196,910.

Education and Charity.—The school board is appointed by the mayor. Since 1904 a merit system has been applied in the advancement of teachers; civil service rules cover the rest of the employees. There are free evening schools. Vacation schools were begun in 1896. As far as possible the school buildings are kept open for school lectures and entertainments, serving as social centres; thus, a more adequate use is made of the large investment which they represent.

In all the public schools, manual training, household arts and

economy, and commercial studies are a part of the curriculum.

A department of scientific pedagogy and child study (1900) seeks to secure a development of the school system in harmony with the results of scientific study of children (the combination of hand and brain training, the use of auditovisual methods, an elastic curriculum during the adolescent period, etc.). Enrolment in the schools in Sept. 1950 totalled 380.610. The teaching staff numbered 13,565. In 1950 the sum of $5,786,177 was devoted to new school buildings. There were 47 high schools and 343 grade schools in that year.

Hospitals, infirmaries, dispensaries, asylums, shelters and homes for the defective, destitute, orphaned, aged, erring, friendless and incurably diseased; various relief societies; and associations that sift the good from the bad among the mendicant, the economically inefficient and the viciously pauper represent the charity work of the city. The most important charitable societies of the city are the United Charities of Chicago (1909), the United Hebrew charities (1857) and the Associated Jewish charities (1900). A famous institution is Hull house, a social settlement of women, which aims at being a social, charitable and educational district centre. It was established in 1889 by Jane Addams, who became the head worker, and Ellen Gates Starr. It includes an art building, a free kindergarten, a fine gymnasium, a crèche and a diet kitchen and supports classes, lectures and concerts. It has had a very great influence throughout the United States.

The major portion of social work in Chicago is performed by 38 general-welfare agencies, 24 general-health agencies, 110 hospitals and 73 dispensaries, 55 infant-welfare centres, 34 agencies for family relief and rehabilitation, 148 child-caring institutions, 70 boarding clubs and hotels for men and women, 29 employment and vocational-guidance organizations, 60 homes and emergency shelters for adults, 49 summer camps, 60 institutions for civic, legal and protective work. There are also institutions for the shelter of abandoned and stray dogs, cats and other animals. The total financial outlay, public and private, for such work was estimated by the Welfare council of metropolitan Chicago at $114,347,700 for 1948. One of the most important municipal undertakings is the Municipal Tuberculosis sanitarium, erected after 1909, in which year a site of 164 ac. was acquired in the northwestern part of the city.

Population.—Of the total population of Chicago as counted in 1940, 672,705 out of a total of 3,396,808 were foreign-born immigrants, 2,441,859 of native white and of mixed parentage, 277,731 Negro and 4,513 were of other races including Chinese, Japanese and American Indian. The effect of the restrictive immigration laws enacted after World War I was notable in the population of Chicago. A heavy influx of native-born white population from the farms and smaller cities, the growth of the Negro population and an increased influx of Mexicans, not subject to the quota restrictions imposed upon Europe and the eastern hemisphere, had discernible effects, but the business and political life of the city remained influenced by national and racial blocs. There are about 42 nationalistic and racial organizations of one kind or another which maintain secretariats in the business district, and many others with headquarters in outlying parts of the city. The largest, most completely organized and politically influential nationalistic groups are the Germans and Irish—very much "Americanized" and losing cohesion—Poles, Swedes, Czechs, Italians, Yiddish-speaking Jews. There are still approximately 40 or more languages spoken in Chicago, and many sections of the city are to all intents and purposes foreign quarters, but the process of assimilation made the city much more homogeneous than it was at the beginning of the 20th century. In 1920 the Negro population was 109,594, an increase of 148.5% over the preceding census. The influx of Negroes was due to the demand for unskilled labour, especially in the packing industry, during World War I, when European immigration was slight. A shortage of housing facilities for these Negro labourers was one of the underlying causes of the race riots of 1919. The Negro influx slackened during the industrial depression of 1920–21, to be resumed in 1923, but in the depression years it again declined. Negroes continued to come to Chicago throughout the decade 1940–50. Increases in the population also occurred through an excess of births over deaths. The estimate for 1950 was about 500,000.

The Chicago Housing authority is a municipal corporation, empowered by the state of Illinois, with five commissioners, serving without pay as appointees of the mayor of the city subject to state housing board approval, to build and operate public-housing projects in Chicago with federal, state and local funds and to aid in clearing and redeveloping the city's blighted areas.

Partly because of the high percentage of youthful adults in the population of Chicago, drawn to the city from other lands and from the rural districts and smaller cities of the United States, the death rate of the city is among the lowest urban rates in the U.S. Births maintain a lead over deaths, so that the city has a substantial, natural rate of increase of population, irrespective of immigration. The growth of Chicago has been remarkable even for U.S. cities. Any resident of four-score years living in 1900 had seen it grow from a frontier military post among the Indians to a great metropolis, fifth in size among the cities of the world. In 1828 what is now the business centre was fenced in as a pasture; in 1831 the Chicago mail was deposited in a dry-goods box; the tax levy of 1834 was $48.90, and a well which constituted the city water works was sunk at a cost of $95.50; in 1843 pigs were barred from the town streets. Such facts impress upon one, as nothing else can, the rapid growth of the city.

History.—The river Chicago (an Indian name of uncertain meaning, but possibly from Ojibwa *she-kag-ong*, "wild onion place") was visited by Louis Jolliet and Jacques Marquette in 1673, and later by René Robert Cavellier, sieur de la Salle and others. It became a portage route of some importance, used by the French in their passage to the lower Illinois country. In 1804 the United States established Ft. Dearborn there. In 1812, during the Indian War of Tecumseh, the garrison and settlers, who had abandoned the fort and were retreating toward safety, were attacked and overpowered by the savages about 2 mi. S. of the fort. The fort was re-established and fitfully occupied until its final abandonment in 1837.

When Cook county was organized in 1831, Chicago, then a tiny village, became the seat of justice. It became a town in 1833 and a city in 1837. By that time Chicago was confident of its future. The federal government had begun the improvement of the harbour, and the state had started the Illinois and Michigan canal. There was a federal land office also, and the land speculator and town promoter had opened a chapter of history more picturesque, albeit sordid, than in any of the old French days. The giant growth of the lake trade had drawn attention before railway connection was secured with the east in 1852, making progress even more rapid thereafter. During the Civil War a large prison camp for Confederate prisoners, Camp Douglas, was maintained at Chicago. In 1870 the city had 306,605 inhabitants and was already a commercial centre of immense importance. In 1871 it suffered a terrible calamity. On Oct. 8 a fire broke out near the lumber district on the west side. Two-thirds of the city's buildings were wood, and the summer had been excessively dry, while to make conditions worse a high and veering wind fanned the flames. The conflagration leaped the river to the south and finally to the north side, burned over an area of three and one-third miles, destroyed 17,450 buildings and property valued at $196,000,000 and rendered almost 100,000 people homeless; 250 lost their lives. The flames actually travelled two and one-fourth miles in an air line within six and one-half hours. Thousand of persons, fleeing before the flames and firebrands, sought refuge on the shore and even in the waters of the lake. Robbery, pillage, extortion, orgies and crime added to the general horror. In the south side the fire was checked on the 9th by the use of gunpowder; in the north (where the water works were early destroyed) it had extended almost to the prairie when rainfall finally ended its ravages, after about 27 hr. of destruction. A vast system of relief was organized and received generous aid from all parts of the world.

The money contributions from the United States and abroad were $4,996,782; of this, foreign countries contributed nearly $1,000,000 (England half of this). These funds, which were over and above gifts of food, clothing and supplies, were made to last

2. La Salle street, in the financial district. In the background is the Board of Trade building
3. A view along Michigan avenue. The low building at the right is the Art Institute
4. The "gold coast" residential section of downtown Chicago, and Oak street beach
5. Cattle pens at the Union Stock Yards in Chicago during the yarding period before sale on the open market. There are approximately 13,000 pens in the yards for the housing of livestock.
6. Six of the bridges spanning the Chicago river near its entrance into Lake Michigan. In centre background is the Merchandise Mart

till the close of 1876 Out of them temporary homes were provided for nearly 40,000 people; barracks and better houses were erected, workmen were supplied with tools and women with sewing-machines; the sick were cared for and the dead buried; and the poorer classes of Chicago were probably never so comfortable as during the first two or three years after the fire. The rebuilding of the city was accomplished with wonderful rapidity. The business district was largely rebuilt within a year, and within three there were few scars of the calamity. Wood was barred from a large area, and a new Chicago of brick and stone, larger, finer and wealthier, had taken the place of the old. Business and population showed no setback in their progress. The solidity and permanence of this prosperity were confirmed during the financial panic of 1873, when Chicago banks alone, among those of the large cities of the country, continued steadily to pay out current funds.

In its later history Chicago became a storm centre of labour troubles, some of them of especially spectacular character. There were great strikes in the packing industry in 1886, 1894 and 1904. But more noteworthy are the railway strike of 1894 and the unsuccessful teamsters' strike of 1905. The former began in the works of the Pullman Car company, and its leader was Eugene Victor Debs. When the contentions of the Pullman employees were taken up by the American Railway union, the strike immediately extended to tremendous proportions. Chicago, as the greatest railway centre of the country and the home of the strike, was naturally the seat of the most serious complications. There was much rioting and destruction of property, and the railway service was completely disorganized. Pres. Grover Cleveland, on the ground of preventing obstruction of the mail service, and of protecting other federal interests, ordered a small number of federal troops to Chicago. Gov. J. P. Altgeld denied the inability of the state to deal with the difficulty, and entered a strong protest against federal interference; but he did nothing to put down the disorder. Federal troops entered the state, and almost immediately the strike collapsed. The high officials of the Railway union, for ignoring a court injunction restraining them from interfering with the movement of the mails, were imprisoned for long terms for contempt of court.

Out of the strike in the McCormick works in 1886 there sprang another famous incident in Chicago's history. The international anarchists of Chicago had been organized in groups about two years earlier, and were very active. They were advocating a "general strike" for an eight-hour day, and the tense excitement among the labourers of the city, because of the McCormick strike, induced unusually extreme utterances. There was a riot at the McCormick works on May 3, in which several men were killed by the police. An anarchist meeting was called for the next day at the Haymarket, a square in Randolph street, and when the authorities judged that the speeches were too revolutionary to be allowed to continue, the police undertook to disperse the meeting. A bomb was thrown, and many policemen were injured, seven fatally. No person could be proved to have thrown the bomb, or to have been directly implicated in its throwing; but on the ground that they were morally conspirators and accomplices in the killing, because they had repeatedly and publicly advocated such acts against the servants of government, 7 anarchists were condemned to death. An application to the United States supreme Court for a writ of error was unanimously refused.

Four were hanged, one committed suicide, two had their death sentence commuted to life imprisonment; an eighth was sentenced to imprisonment for 15 years. Governor Altgeld in 1893 pardoned the three in prison on the ground that the jury was "packed" and consequently incompetent, that no evidence connected the prisoners with the crime and that the presiding judge was prejudiced (*see* an article by Judge J. E. Gary, who presided at the trial, in the *Century Magazine* [April 1893]).

Chicago remained essentially a union town. Organization of unskilled workers gained after 1936, causing one bitter riot with ten deaths in 1937. After World War I the effect of the greater mechanization of industry, the increased productivity of labour, the immigration restrictions and the maintenance of high wage rates without strikes was evidenced in greater industrial tranquillity. In the building trades, however, labour unionism remained a powerful factor, despite a great deal of faction and many charges of corruption and of collusion between labour leaders and gangsters pursuing unlawful avocations. A later phase of trade-union organization was the extension of unionism among small merchants and shopowners, for purposes of price maintenance and limitation of competition. The extension of this form of organization was linked with bombing, terrorism and extortion, but the greater part of the trade-union movement in Chicago was not affected by such methods.

The 400th anniversary of the discovery of America was commemorated by the World's Columbian exposition held at Chicago. The site was in Jackson park and the adjoining Midway, and included 686 ac., of which 188 were covered by buildings. On Oct. 21, 1892—corresponding to Oct. 12, 1492, O.S.—the grounds were formally dedicated, and on the following May 1, opened to the public, continuing open for six months. The number of paid admissions was 21,500,000; of total admissions, 27,539,521. The buildings, planned by a commission of architects, of whom John W. Root and Daniel H. Burnham of Chicago were responsible for the general scheme, formed a collection of remarkable beauty.

Forty years later Chicago threw open the gates of its second international exposition, A Century of Progress, celebrating the centennial of the incorporation of the municipality. In the 1933 period the paid attendance was 22,320,456 and in 1934, 16,314,480. Bold experimental architecture and startling effects in colour and lighting were the dominant features of the exposition, which laid emphasis upon scientific and technological development. The success of the exposition in the midst of a world-wide depression had a stimulating effect upon the city's morale as well as its business.

In the late '90s the city began a great civic awakening. A civil service system was inaugurated in 1895. The salaries of the councilmen were raised with good results. Numerous reform associations were started to rouse public opinion, such as the Citizens' Association of Chicago, organized in 1874, the Civic federation (1894), the Municipal Voters' league (1896), the Legislative Voters' league (1901), the Municipal Lectures association (1902), the Referendum League of Illinois (1901), the Civil Service Reform Association of Chicago, the Civil Service Reform Association of Illinois (1902), the Merchants' club, the City club (1903), Law and Order league (1904) and Society of Social Hygiene (1906); and many of the women's clubs took an active part. They stood for effective enforcement of the laws, sanitation, pure food, public health, the improvement of the schools and the widening of their social influence and (here especially the women's clubs) aesthetic, social and moral progress. The Merchants' club reformed the city's bookkeeping, and secured the establishment (1899) of the first state pawnbrokers' society. The Civic federation demonstrated (1896) that it could clean the central streets for little more than half what the city was paying (the city later saved the difference); it originated the movement for vacation schools and other educational advances, and started the Committee of One Hundred (1897), from which sprang various other reform clubs. The Municipal Voters' league investigated and published the records of candidates for the city council, and recommended their election or defeat. Moreover, a municipal museum was organized in 1905, mainly supported by private aid, but in part by the board of education, in order to collect and make educational use of materials illustrating municipal administration and conditions, physical and social.

The reform movement in its various phases came to its full tide under the administration of Carter H. Harrison, Jr., who was elected to his fifth term in 1911, thereby equalling his father's record of elections to the highest office within the gift of the people of the city. In 1912 State's Attorney John E. W. Wayman closed the city's tolerated vice district, and it was not allowed to operate thereafter.

With the adoption of the prohibition amendment to the federal constitution in Jan. 1919, and the flocking to the city of many adventurous characters attracted by the building boom and the

prosperity following the war, there was a growth of violent crime in Chicago. The huge profits of the illicit liquor trade led to the organization of powerful criminal gangs to exploit the traffic, and competiton between these organizations led to murder and banditry, which attracted world-wide attention. The most notorious gang leader of this period was Al ("Scarface") Capone.

Growth of the gang system coincided with an era of spoils politics under Mayor William Hale Thompson, Republican (1915–23 and 1927–31). The reformist interlude of Mayor William E. Dever, Democrat (1923–27) did not abate growing disorders. In 1931 Chicago returned to its normal Democratic moorings under Mayor Anton J. Cermak, a machine politician but a man of forceful character who began a cleanup of the city. He was shot by a criminal anarchist who was attempting to kill President-elect Franklin D. Roosevelt and hit Cermak by mistake at Miami, Fla.

Cermak died March 6, 1933, but his organization remained firmly entrenched under Mayor Edward J. Kelly, Democrat. Repeal of national prohibition in 1933 followed by vigorous police and court offensives for a brief time quelled the organized criminal elements.

Under the centralized regime introduced by Cermak, Chicago politics, long a quasi-tribal and feudal system under ward and district leaders, developed along the lines of Tammany in New York —domination by a powerful organization brooking no rebellion within its ranks. In this change Chicago witnessed the passing of the last of its frontier-town characteristics, which persisted for a century.

Kelly, together with "Pat" Nash, built the Cermak political machine into one of the most powerful vote-getting organizations in the country. Kelly became strong enough, with the help of the bosses of other cities, to defeat the nomination of Henry A. Wallace as vice-president in 1944 and nominate Harry S. Truman, paving his way to the presidency.

Lawlessness, which flourished gangland style during the prohibition era, continued on the same violent scale. In 1947 Chicago had another mild reform when Kelly stepped out as mayor and another Democrat, Martin H. Kennelly, a prominent businessman, took over as mayor.

Nash had died and Kelly went into nominal retirement from politics before his death in 1950. His successor as head of the powerful Democratic machine was Jacob M. Arvey, an attorney who had risen in party ranks under the Kelly regime.

Because of its central location, Chicago has been the United States' most famous convention city and the scene of much national political history. Lincoln (1860), U. S. Grant (1868), James A. Garfield (1880), Cleveland (1884 and 1892), Harrison (1888), Theodore Roosevelt (1904), William Howard Taft (1908), Warren G. Harding (1920) and F. D. Roosevelt (1932, 1940) were all nominated for president in Chicago in addition to a number of unsuccessful candidates nominated in stirring conventions.

H. L.; F. F. Rx.)

CHICAGO, BURLINGTON & QUINCY RAILROAD COMPANY, popularly known as the "Burlington route," incorporated in Illinois Feb. 12, 1849, as the Aurora Branch Railroad company, and adopted its present name Feb. 14, 1855. The railroad commenced operation in 1850 over 12 mi. of track between Aurora, Ill., and West Chicago. Thereafter, by construction and by acquisition of other lines, it grew to about 9,000 mi., extending from Chicago and St. Louis, Mo., to Minneapolis, Minn., Omaha, Neb., Kansas City, Mo., Denver, Colo., and Billings, Mont. More than 97% of the capital stock of the Burlington is owned in equal parts by the Northern Pacific and Great Northern railways, with which it connects at St. Paul, Minn., and Billings to form through routes to the Pacific northwest. The Burlington, in turn, controls the Colorado and Southern railway, which provides a rail route from Wyoming to the Gulf of Mexico. The Burlington system, including the Colorado and Southern and subsidiaries, totals about 11,000 mi. in 14 states.

In 1951 the company, excluding its interest in subsidiary companies, had an investment in railway operating property of about $626,000,000 and $171,000,000 of funded debt and $171,000,000 par value capital stock outstanding.

The railroad was handling more than 50,000,000 tons of commercial freight each year, of which approximately 40% was mine products, 20% agricultural products, 5% livestock and animal products, 5% lumber and forest products and 30% manufactures and miscellaneous freight.

It carried 4,038,511 passengers during 1950 besides a heavy commutation traffic in Chicago suburban territory. On April 9, 1934, the Burlington inaugurated America's first diesel-powered streamline train, the "Zephyr."

CHICAGO, MILWAUKEE, ST. PAUL AND PACIFIC RAILROAD COMPANY. The Chicago, Milwaukee, St. Paul and Pacific Railroad company, incorporated March 31, 1927, was organized under the laws of the state of Wisconsin in order to take over the properties of the Chicago, Milwaukee and St. Paul Railway company, a Wisconsin corporation (organized May 5, 1863, as the Milwaukee and Saint Paul Railway company, "Chicago" having been added to its name Feb. 11, 1874), after receivership and mortgage foreclosure proceedings, culminating in sale of the property on Nov. 22, 1926; and reorganized after bankruptcy by amendment of charter but without change of name, effective Dec. 1, 1945.

The company's history from its early days on records the acquisition of smaller lines until a system developed, extending from Chicago and Milwaukee, Wis., to Saint Paul, Minn., Kansas City, Mo., Omaha, Neb., and many points in the states of Wisconsin, Iowa, Minnesota, North Dakota and South Dakota. On Jan. 1, 1913, it acquired the property of its subsidiary, the Chicago, Milwaukee and Puget Sound Railway company, which operated 2,081 mi. of road, including branch lines, extending from Mobridge, S.D., to Seattle and Tacoma, Wash. Subsequently, other lines were acquired, including the Idaho and Washington Northern railroad, Big Blackfoot Railway company, Tacoma Eastern Railroad company, Puget Sound and Willapa Harbor Railway company, Seattle, Port Angeles and Western Railway company, Bellingham and Northern Railway company, Milwaukee Terminal Railway company, Gallatin Valley Railroad company and Chicago, Milwaukee and Gary Railway company. The properties of the Chicago, Terre Haute and Southeastern Railway company (known as the Terre Haute), which had been operated by the Milwaukee or its predecessors since July 1, 1921, under a 999-year lease, were conveyed to the Milwaukee company by deed dated Dec. 31, 1948. On Dec. 31, 1950, the company operated 10,671 mi. of railroad, of which 9,843 were solely owned, 165 jointly owned and 663 operated under trackage rights. It operated in the states of Idaho, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Montana, Nebraska, North Dakota, South Dakota, Washington and Wisconsin. The company on that date owned 838 steam, 60 electric and 232 diesel-electric locomotives; 58,787 freight-train cars; 1,119 passenger-train cars, 13 rail-motor cars; 1 tugboat; 5 car barges; and 3,375 units of company service equipment. (J. W. Ss.)

CHICAGO, ROCK ISLAND AND PACIFIC RAILROAD COMPANY, a U.S. railroad extending from Chicago, Ill., westward, northwestward and southward. It dates from a special act of the Illinois state legislature, approved Feb. 27, 1847, and amended Jan. 27, 1851. Construction began in Chicago Oct. 1, 1851, and the first train ran from Chicago to Joliet, Ill., a distance of 40 mi., on Oct. 10, 1852. The road reached the Mississippi river on Feb. 22, 1854, and there was constructed there the first

bridge over that river between Rock Island, Ill., and Davenport, Ia., which was opened on Sept. 1, 1854.

At the close of 1950 the Rock Island comprised about 8,000 mi. running through 14 middle western states, and extending from Chicago to Denver and Colorado Springs, Colo., and Santa Rosa, N.M., and from St. Paul, Minn., to Fort Worth, Dallas and Houston, Tex., with lines into St. Louis, Mo., Memphis, Tenn., Kansas City, Mo., Omaha, Neb., Des Moines, Ia., Oklahoma City, Okla., Topeka, Kan., Eunice, La., and the principal Mississippi valley centres. The total capitalization of all the Rock Island lines as of Dec. 31, 1950, was approximately $295,436,542, including $211,409,442 of capital stock. The railroad on that date was largely dieselized.

CHICAGO, THE UNIVERSITY OF, an institution of higher learning in Chicago, Ill., founded in 1891 and opened Oct. 1, 1892; privately supported, coeducational. Though originally established as a Baptist university, requirements for Baptist membership on the board of trustees were progressively relaxed by the Northern Baptist convention, and the university is now nondenominational. Its presidents have been William Rainey Harper (Sept. 18, 1890–Jan. 10, 1906), Harry Pratt Judson (Feb. 20, 1907–retired Feb. 20, 1923), Ernest DeWitt Burton (July 12, 1923–May 26, 1925), Max Mason (Oct. 1, 1925–resigned May 7, 1928), Robert M. Hutchins (July 1, 1929–June 30, 1945) and Ernest C. Colwell (June 30, 1945–June 30, 1951). Hutchins' title was changed by trustee action to that of chancellor in 1945. He resigned on Dec. 19, 1950 to become associate director of the Ford foundation and was succeeded as chancellor by Lawrence A. Kimpton on April 12, 1951.

Growth of the university in facilities, program and influence was rapid, largely because of the combination of John D. Rockefeller, its founder, who provided liberal and consistent financial support, and Harper, who had original educational ideas and enthusiasm. Harper gathered a distinguished faculty, including nine presidents of colleges and universities, so that from the start the university was eminent in research and advanced study.

Harper's educational organization continued without essential change until 1930 when the "Chicago plan" was adopted. The college of the "Chicago plan" became a two-year unit concerned with general education, much as Harper had conceived the function of the junior college he established in the university in 1891. The college broke largely with academic tradition in that it established general courses a year in length and abolished credit accumulation, the student meeting the requirements by passing comprehensive examinations which he could take, without regard to time spent in class, whenever he was able.

In 1942, after five years of experimentation in University High school, the collegiate work was relocated. Students were admitted at the end of the sophomore year of high school for a program normally requiring four years; upon its completion they received the bachelor's degree. This relocation, the complete emphasis of the college on general as opposed to specialized education and the awarding of the bachelor's degree two years earlier than in conventional colleges aroused considerable controversy among educators of the country. Students in the college must satisfy requirements by passing 14 comprehensive examinations or being excused through the placement tests given upon entrance to determine the educational achievement of each student in relation to the college definition of general education.

With the relocation of the college, the program for work for the master's degree became a three-year program in one of the four divisions or in certain of the professional schools.

An administrative reorganization also was made in 1930, establishing largely the present university organization: the college; four divisions—the physical, biological and social sciences and the humanities; six professional schools—business, divinity, law, library science, medicine and social service administration; the library (with 24 departmental units); the press; and university extension (for study off-campus, at a downtown centre and through correspondence). This grouping includes the Oriental institute, engaged in research on earlier civilization; Yerkes observatory, Williams Bay, Wis. (whose astronomers also staff, under a co-operative agreement, the University of Texas' McDonald observatory, Mt. Locke, Tex.); the laboratory schools (nursery, elementary and high school through the tenth grade); an orthogenic school and three institutes—for study of metals, for nuclear studies, and radiobiology and biophysics, established in 1945. Much of the research and advanced study is conducted through interdivisional and interdepartmental committees; for example, the committee on cancer includes 15 departments and 2 institutes. The University of Chicago Press, oldest in continuous publication in the country, publishes 25 learned journals and an average of about 50 books a year.

The university is located approximately eight miles south of the downtown section of Chicago, with frontage for three-fourths of a mile on both sides of the Midway Plaisance, which links Jackson and Washington parks. The campus of 110 ac. has about 85 buildings, most of which are collegiate Gothic in architectural style and grouped in quadrangles. Newer buildings, however, are departing from the Gothic style, though general uniformity is maintained with limestone exteriors. In addition to the building during Harper's administration there was extensive construction during the period 1924–32, which trebled floor space, and following World War II, in which new hospitals, the administration building, the accelerator building (housing a 450,000,000-ev synchrocyclotron and a 100,000,000-ev betatron) and laboratories for the new institutes in nuclear energy, radiobiology and biophysics, and metals were the principal units. The plant of the university had a book (cost) value of $57,315,478 as of June 30, 1950.

Harper's plans for the university were made possible by the generosity of John D. Rockefeller, who personally gave a total of $34,708,000 from 1890 to 1910. In addition, the foundations which he established had provided, through June 30, 1950, more than $49,700,000 and John D. Rockefeller, Jr., has made personal gifts of about $5,800,000. The university, however, has had thousands of other donors and has had large support particularly from Chicago citizens. From 1890 through June 30, 1950, gifts from all sources aggregated $171,621,233, of which $90,782,482 had been received during the 21 years of Chancellor Hutchins' administration. Endowment on June 30, 1950, was $70,972,026. Expenditures under the university regular budget for 1949–50, comprising continuing educational and research activities, were $16,566,019; for auxiliary enterprises (residence and dining halls, International House, press, bookstore, etc.), $3,970,397. With the restricted expendable funds section of the budget, representing gifts for designated current purposes and for nonprofit contracts with the U.S. government for research, instruction and management, the consolidated budget expenditures totalled $42,425,735 for the 1949–50 fiscal year. The peak number of students enrolled in the university was in 1946–47 when there were 14,432 different students. The second largest year was 1929–30, with a total of 14,245 different students. For 1949–50, this figure was 12,316. (W. V. M.)

CHICAGO ACADEMY OF SCIENCES, THE, an institution organized at Chicago, Ill., on Jan. 13, 1857, "to promote and diffuse scientific knowledge," and one of the oldest scholarly bodies existing in Illinois. The collections of the academy, considered at the time among the most valuable in the United States, were in the Chicago fire of 1871.

With the erection of the new building in Lincoln park in 1893 by Mathew Laflin, a new impetus was given to the establishment of a fine scientific museum. Exhibits featuring the wild life, flora and physical characteristics of the Chicago region were opened daily to the public. (H. K. G.; X.)

CHICAGO AND NORTH WESTERN RAILWAY COMPANY, comprising 7,923 mi. operated as of Dec. 31, 1950, in Illinois, Iowa, Nebraska, Wyoming, Wisconsin, Michigan, Minnesota, South and North Dakota. It owned (1950) 736 steam locomotives and 336 diesel-electric power units, not including 6 diesel-electric power units jointly owned with the Union Pacific railway; 1,179 passenger-train cars; and 45,171 freight-train cars.

The balance sheet, as of Dec. 31, 1950, showed investment in property, less depreciation and amortization, of $366,848,157, investments including capital and other reserve funds and sinking

funds of $78,447,814 and total assets of $512,844,979. Capital stock consisted of $81,554,400 common and $91,390,300 preferred.

Its funded debt held by the public was $177,472,669. The Interstate Commerce commission's bureau of valuation reported, as of Dec. 31, 1949, that cost of reproduction less depreciation, value of lands and rights, working capital and material and supplies aggregated $728,512,485. Gross operating revenue for 1950 was $188,901,154 and net railway operating income was $9,132,717. It was the first railroad to operate into the city of Chicago, commencing in Oct. 1848, and expanding from that date to its present proportions.

CHICAGO HEIGHTS, a city of Cook county, Ill., U.S., on federal highway 30, 28 mi. S. of Chicago. It is served by the Chicago and Eastern Illinois, the Chicago, Milwaukee, St. Paul and Pacific, the Elgin, Joliet and Eastern, the New York Central, Baltimore and Ohio Chicago terminal and the Chicago Heights Terminal Transfer railways. In 1900 the population was 5,100; in 1920, 19,653; in 1940, 22,461; and in 1950, 24,369 by the federal census.

Chicago Heights is an important industrial centre, manufacturing chemicals, alloy and steel products, glass specialties, roofing, textiles, school supplies, fertilizers, paints and various other commodities. The city was incorporated in 1901.

CHICAGO SANITARY AND SHIP CANAL, in the United States, is an engineering development of special importance to the city of Chicago and surrounding districts. It was first opened in 1900 and the cost of construction with improvements has been about $70,000,000. Before the construction of the canal Chicago discharged sewerage into Lake Michigan, which was also the source of the water-supply. Such serious contamination resulted that ultimately the extension of water intake pipes for a distance of 4mi. out into Lake Michigan failed to avoid dangerous pollution.

A few miles west of the city, a low limestone ridge marks the division of the watersheds leading to the Des Plaines and Chicago rivers. The Des Plaines, to the west of the ridge, flows southwest to the Illinois river and thence to the Mississippi river. The Chicago river, to the east of the ridge, normally drains into Lake Michigan. A canal channel was dug through the ridge by which the Chicago was connected with the Des Plaines river and at the same time the flow in the Chicago river was reversed from east to west. The sewage of the city is collected in great central city mains, passed through sewage treatment plants and the purified effluent turned into the canal and carried down to the Gulf of Mexico. The canal is 34mi. long, 160ft. wide and 24ft. in depth. In 1939 an average of 1,500 cu.ft. per second was being drawn from Lake Michigan to carry away the drainage of Chicago. Another phase of the project, completed in 1933, was the creation of an all-water route with a minimum depth of 9ft. between the Great Lakes and the Gulf of Mexico.

CHICANE, the pettifogging subterfuge and delay of sharp law-practitioners, also any attempt to gain unfair advantage by petty tricks. A more common English form of the word is "chicanery." Chicane was also used until recent years as a term in the game of bridge for the points a player might score if his hand contained no trumps. Chicane is no longer scored, but the term is still used. The word is French, derived either from *chaugān,* Persian for the stick used in the game of polo, still played on foot and called *chicane* in Languedoc (*cf.* the military use of *chicaner,* to take advantage of slight variations in ground), or from *chic,* meaning little or petty, from the Spanish *chico,* small.

CHICHA, a fermented liquor resembling beer made by the natives of South America from Indian corn.

CHICHELEY, HENRY (1364–1443), English archbishop, founder of All Souls college, Oxford, was born, the son of a yeoman, at Higham Ferrers, Northamptonshire. He seems to have passed from Winchester college to New college, Oxford, where he took his B.A. in 1392. He was then ordained sub-deacon, but he already held the living of Llanvarchell, in the diocese of St. Asaph. About 1394 he went up to London to practise as an advocate in the principal ecclesiastical court, the court of arches, and from that time an extraordinary number of posts fell to him. In 1396 he was presented to the rectory of St. Stephen's, Walbrook, and, being ordained deacon and priest later on in the year, he was made archdeacon of Dorset in 1397, and in 1399, canon of the collegiate church of Abergwili, North Wales. In Feb. 1402, he was allowed to use a bull of the pope "providing" him to the chancellorship of Salisbury cathedral and canonries in the nuns' churches of Shaftesbury and Wilton, and in Jan. 1402–3 he became archdeacon of Salisbury. In May 1404, Boniface IX. provided him to a prebend at Lincoln, notwithstanding that he already held prebends at Salisbury, Lichfield, St. Martin's-le-Grand and Abergwili, and the living of Brington.

In July 1405, Chicheley began his diplomatic career by a mission to the new Roman pope, Innocent VII., who was professing his desire to end the papal schism by resignation, if his French rival at Avignon would do likewise. In 1406 he was appointed to treat for peace with the French king, and in the following year he was sent to the new pope, Gregory XII., to end the schism. The pope provided him to the bishopric of St. David's and gave him a bull granting him the right to hold all his benefices with the bishopric.

In Jan. 1409, Chicheley was chosen by the convocation of Canterbury to attend the Council of Pisa, which withdrew obedience from both existing popes and in June elected a new pope. Chicheley now became the subject of a leading case, the court of king's bench deciding, after three successive terms, that he could not hold his previous benefices with the bishopric, and that a papal bull could not supersede the law of the land (*Year-book* ii. H. iv. 37, 59, 79). Accordingly he had to resign livings and canonries wholesale (April 28, 1410), and was enthroned at St. David's in May, 1411. He was with the English force under the earl of Arundel which accompanied the duke of Burgundy to Paris in Oct. 1411, and there defeated the Armagnacs; and in July 1413 was sent by Henry V., with the earl of Warwick, to France to conclude peace. On the death of Archbishop Arundel he was nominated to the archbishopric.

These dates are important as they save Chicheley from the charge, versified by Shakespeare (*Henry V.* act i. sc. 2) from Hall's *Chronicle,* of having tempted Henry V. into the conquest of France for the sake of diverting parliament from the disendowment of the Church. As a matter of fact, the parliament at Leicester, in which the speeches were supposed to have been made, began on April 30, 1414 before Chicheley was archbishop, and the rolls of parliament show that he was not present in parliament. Moreover, parliament was so far from pressing disendowment that on the petition of the Commons it passed a savage act against the heresies "commonly called Lollardry" which "aimed at the destruction of the king and all temporal estates," making Lollards felons and ordering every justice of the peace to hunt them down.

Chicheley was present at the siege of Rouen, and the king committed to him the negotiations for the surrender of the city in Jan. 1419 and for the marriage of Katherine. He crowned Katherine at Westminster (Feb. 20, 1421), and in Dec. baptized her child, Henry VI.

Chicheley is renowned chiefly for his educational foundations. He endowed a chest or loan fund for poor scholars at New college, and another for the university at large. He founded at least three colleges, one at Higham Ferrers and two at Oxford. The licence for the first was given by Henry V. in May 1422. It was closely modelled on Winchester college, and to it was attached an almshouse for 12 poor men. His first Oxford college, St. Bernard's, was founded under licence in mortmain in 1437 for Cistercians. It was suppressed with the Cistercian abbeys in 1539 and granted in 1546 to Christ Church, Oxford, who sold it to Sir Thomas Pope in 1553 for the present St. John's college. The patent for All Souls college, dated May 20, 1438, is for a warden and 20 scholars, to be called "the Warden and College of the souls of all the faithful departed," to study and pray for the souls of Henry V. and Henry VI. and all Englishmen who had died in the wars with France. A papal bull for the college was obtained on June 21, 1439; and further patents for endowments from May 11, 1441, to Jan. 28, 1443, when a general confirmation charter was obtained, for which £1,000 (£30,000 at least of our money) was paid. Only about a quarter of the whole endowment was derived

from alien priories bought by Chicheley from the crown. The rest, particularly the manor of Edgware, which made the fortune of the college, was bought from private owners. Early in 1443 the college was opened by Chicheley with four bishops in state. The statutes, not drawn up until April 2, 1443, raised the number of the college to 40, 16 of whom were to be "jurists" and 24 students of arts and philosophy or theology.

Chicheley died on April 12, 1443, and was buried in Canterbury cathedral.

CHICHEN-ITZÁ or **CHICHEN,** the ruins of an ancient Mayan city of that name, in the south-central part of the State of Yucatán, Mexico, near the boundary of Quintana Roo, about 20° 30′ N. lat. and 88° 30′ W. longitude. The dry, waterless region round about Chichen-Itzá is of limestone formation, with only an underground water supply, available in but a few places called *cenotes* by the Mayans, where the limestone cap has fallen into the caves through which the water flows. Two large *cenotes* determined the location of the city and gave it its distinctive name, *Chi,* which in Mayan means mouths, *chen,* wells, and *Itzá* the name of the particular Mayan tribe or group which first settled there, the whole meaning the "Mouths of the Wells of the Itzá."

Founded not later than A.D. 530, the settlement for about the first century constituted but a frontier post of a Mayan civilization, "The Old Empire," which at that time was flourishing in the much greater centres to the southward—Copan, Tikal, Quiriqua, Palenque and a dozen other equally important cities. When about a century later these great flourishing southern cities were finally abandoned, Chichen-Itzá was also temporarily abandoned, A.D. 668, and the Itzá trekked westward across Yucatán to a new capital, Chakanputun, south of the modern Campeche. Chakanputun was burned in A.D. 944 and the "Holy Men of the Itzá" led their people back to the "Mouths of the Wells of the Itzá" where, in A.D. 964 they re-established their *lares* and *penates* and rebuilt their shrines and altars.

It was the period of the founding of "The New Empire" with Uxmal, Mayapan, and a group of satellite cities, sharing with Chichen-Itzá a superb renaissance of Mayan culture and power. In A.D. 1004 the three greater cities formed an alliance, the League of Mayapan, and the calm and order and prosperity that followed gave rise to a golden age of Mayan religion, science and art, with majestic temples and superb sculptures scattered about the land. At Chichen most of the middle section of the city lying south and west of the Thousand Columns, was built at this time, graced by the Akab'tzib (House of the Dark Writing), the Chichanchob (Red House), the House of the Deer, and parts of the Monjas (Monastery).

In 1201 the League of Mayapan was disrupted by an attack of the Mayapan people upon the Chichen-Itzá because of conspiracies against the League by Chac Xib Chac (The Very Red Man), the Itzan ruler. With the aid of Toltec and Aztec allies from Central Mexico the Mayapan people conquered the Itzans. Henceforth the city was held in thrall by the Toltec-Aztec allies of the Mayapan group. These Toltec-Aztec conquerors brought with them the worship of the fair, golden-haired god, Quetzalcoatl, the "Feathered Serpent," who became "Kukulcan," the Itzan equivalent. During this period Chichen-Itzá rose to heights of prosperity, prominence and architectural development surpassing anything in its earlier history, and highly adorned temples, sanctuaries and shrines rose as if by magic; the principal temple, the so-called Castillo, covering an acre of ground and rising 100 ft. above the plain; the Thousand Columns enclosing a central plaza of more than 5 ac. with pyramid temples, colonnaded halls, sunken courts, terraces and theatres; the Tlachtli-ground or Ball Court; the Temple of the Jaguars; the Temple of the Tables; the Astronomical Observatory; the High Priest's grave; and a host of others.

The two *cenotes,* or wells, upon which the city depended for its very life, constituted the religious, as well as the economic, centre of the city and its culture. Young Itzan maidens were sacrificed to the gods of the wells, as were all kinds of valuables, in gruesome spectacles that drew thousands to share in the ceremonies and the rites, and gave to the city its "holy" character. The natural setting of the wells, the grandeur of the temples built beside them, the austerity and dignity of the rites, all contributed to the lure, and made Chichen-Itzá the Mecca of the Mayan world for almost two and one-half centuries until about the middle of the 15th century when it was rather suddenly and finally abandoned, only a few stragglers making their homes there and doing homage to the old gods.

See S. G. Morley, "Chichen-Itzá, An Ancient American Mecca," *Natl. Geog. Mag.,* vol. xlvii., No. 1, pp. 63–95 (Jan. 1925). (W. E. E.)

CHICHERIN, GEORGHY VASILIEVICH (1872–1936), Russian statesman, the son of an official in the ministry for foreign affairs, was born in Karaul, province of Tambov. He was educated at a Russian Higher school, and at St. Petersburg (Leningrad) university, and entered the diplomatic service in the archives department of the foreign office. From 1897 onward he was gradually drawn into the revolutionary movement. He resigned from the diplomatic service in 1904, renouncing his estates, and went to Berlin, where he followed closely the German Social-Democratic movement. He was at first attached to the Russian socialist-revolutionary party, but later joined the social-democratic party. He was prevented by illness from taking part in the revolution in 1905. He spent 12 years in revolutionary activities in London, Paris and Berlin, being elected secretary of the foreign central bureau of the Russian Social-Democratic party in 1907. In the same year he was arrested in Berlin for the possession of a false passport, and banished from Prussia. During the World War he assisted the anti-war Labour elements in Great Britain, and organized the relief of Russian political refugees, a philanthropic work which had a revolutionary aspect in maintaining contact with Russian revolutionaries. After the Bolshevik revolution in November, when Russia was no longer considered an ally, but an enemy, Chicherin was imprisoned in Brixton gaol on the ground of "enemy associations." On Jan. 3, 1918 he was exchanged for Sir George Buchanan by the Soviet Government, and banished from England. He returned to Russia, and was appointed People's Commissary for foreign affairs in March 1918. In 1922 he headed the Soviet delegation to the conference at Genoa (April 10–May 19) (*q.v.*), of which the unexpected result was a separate treaty between Soviet Russia and Germany. Chicherin conducted Russian policy continuously, from 1918 to 1930, having a longer tenure of office than any contemporary European foreign minister. (For the policy for which he was responsible during this period, *see* RUSSIA.)

CHICHESTER, a city and municipal borough in the Chichester parliamentary division of Sussex, England, 69 mi. S.W. of London by the Southern railway. Pop. (est. 1938) 16,460. Area, 4.48 sq.mi. It lies in the coastal plain at the foot of a spur of the South Downs, a mile from the head of Chichester harbour, an inlet of the English channel. The Romano-British town on this site was perhaps Regnum or Regni. Situated on one Roman road in direct connection with London and another leading from east to west, Chichester (*Cesseceastre, Cicestre*) remained of considerable importance under the South Saxon kings and it had a mint in 928. Domesday book speaks of 97½ haws, or building plots, in Chichester and a charter of Henry I mentions the borough, but the earliest extant charter is that of Stephen, about 1135, granting the burgesses the rights of a borough and gild merchant, as they held them in the time of William I. This grant shows the Chichester gild merchant to be possibly the oldest in the country. This was confirmed by Henry II *c.* 1155. By a charter of Edward II, the customs of wool, hides and skins were reserved to the king. Edward III directed that the Sussex county court should be held at Chichester. Confirmations of the previous charters were granted by many later sovereigns. James II in 1685 granted the charter now in force. Chichester returned two members to parliament from 1295 to 1867, and one member from then until 1885. Throughout the middle ages Chichester was a place of great commercial importance, Edward III establishing a wool staple there in 1348. Chichester had five fairs in 1889; all but Sloe fair (*c.* 1107–08) were abolished. Fuller mentions the Wednesday market as being famous for corn, while Camden speaks of that on Saturday as the greatest for fish in the county.

The cathedral church of the Holy Trinity was founded towards the close of the 11th century, after the see had been removed to Chichester from Selsey in 1075. It was consecrated in 1108; Bishop Ralph Luffa (1091–1123) was the first great builder, followed by Seffrid II (1180–1204), but disastrous fires led to further building throughout the 13th century. Norman work appears in the nave (arcade and triforium), choir (arcade) and elsewhere; but there is much very beautiful Early English work, as in the choir above the arcade. The nave is remarkable in having double aisles on each side, the outer pair being of the 13th century. The church is also unique among English cathedrals for its detached campanile, a massive and beautiful Perpendicular structure with the top story octagonal. Modern restorations, which include the fine central tower and spire (originally 14th century), the Decorated Lady Chapel and the Perpendicular cloisters, have been effected with great care. The library is a fine late Norman vaulted room; and the bishop's palace retains an Early English chapel. The cathedral is 393 ft. long within, 131 ft. across the transepts, and 90 ft. across the nave with its double aisles. The height of the spire is 277 feet. At the junction of the four main streets of the town, which preserves its Roman plan, stands an octagonal market cross, in ornate Perpendicular style, built by Bishop Story, *c.* 1500, perhaps the finest of its kind in the United Kingdom. The hospital of St. Mary was founded in the 12th century, but the existing buildings are transitional from Early English to Decorated. Its use as an almshouse is maintained. Other ancient buildings are St. Olave's church, in the construction of which Roman materials were used; the Guildhall, formerly a Grey Friars' chapel, of the 13th century; the Canon gate leading into the cathedral close; and the Vicars college. The city retains a great part of its ancient walls, which have a circuit of about a mile and a half, and at least in part, follow the line of Roman fortifications. There is a theological college, a women teachers' training college and a blue-coat school. A new county office building was opened in 1938. The town has a large cattle market and a considerable agricultural trade, but no outstanding industry. A canal connects with Chichester harbour. The diocese includes the whole county of Sussex except a few parishes, with very small portions of Kent and Surrey.

See *Victoria County History*, "Sussex"; Alexander Hay, *History of Chichester* (Chichester, 1804).

CHICHESTER OF BELFAST, ARTHUR CHICHESTER, Baron (1563–1625), lord-deputy of Ireland, second son of Sir John Chichester of Raleigh, Devonshire, was educated at Exeter college, Oxford. He commanded a ship against the Spanish Armada in 1588, and is said to have served under Drake in his expedition of 1595. Having seen further service abroad, he was sent to Ireland at the end of 1598 and was appointed by the earl of Essex to the governorship of Carrickfergus. When Essex returned to England Chichester served under Mountjoy in the war against the rebellious earl of Tyrone, and in 1601 Mountjoy recommended him to Cecil as the fittest person to be entrusted with the government of Ulster. On Oct. 15, 1604, Chichester was appointed lord-deputy of Ireland. He announced his policy in a proclamation wherein he abolished the semi-feudal rights of the native Irish chieftains, substituting for them fixed dues, while their tenants were to become dependent "wholly and immediately upon his majesty." Tyrone and other Irish clan chieftains resented this summary interference with their ancient social organization, and their resistance was strengthened by the ill-advised measures against the Roman Catholics which Chichester was compelled to take by the orders of the English ministers. He himself was moderate and enlightened in his views on this matter, and it was through his influence that the harshness of the anti-Catholic policy was relaxed in 1607. Meantime his difficulties with the Irish tribal leaders remained unsolved. But in 1607, by "the flight of the Earls," he was relieved of the presence of the two formidable Ulster chieftains, the earls of Tyrone and Tyrconnell. Chichester's policy for dealing with the situation thus created was to divide the lands of the fugitive earls among Irishmen of standing and character; but the plantation of Ulster as actually carried out was much less favourable and just to the native population than the lord-deputy desired. In 1613 Chichester was raised to the peerage as Baron Chichester of Belfast, and in the following year he went to England to give an account of the state of Ireland. On his return to Ireland he again attempted to moderate the persecuting policy against the Irish Catholics which he was instructed to enforce; and although he was to some extent successful, it was probably owing to his opposition to this policy that he was recalled in Nov. 1614. The king, however, told him, "You may rest assured that you do leave that place with our very good grace and acceptation of your services"; and he was given the post of lord-treasurer of Ireland. After living in retirement for some years, Chichester was employed abroad in 1622; in the following year he became a member of the Privy Council. He died on Feb. 19, 1625, and was buried at Carrickfergus.

CHICHIBU, PRINCE: *see* Yoshihito.

CHICKADEE, common American name (derived from the call-note) for the black-throated, black-capped titmouse (*Parus atricapillus*), of the northern states and Canada. The brown-capped chickadee (*P. hudsonicus*) is resident in Canada and northern New England. The smaller Carolina chickadee (*P. carolinensis*) breeds in the southeastern states. The mountain chickadee (*P. gambeli*) is resident in the Rocky Mountains and westward, and has a white stripe over the eye. The Alaska chickadee (*P. cinctus alascensis*) is also found in eastern Siberia. The chestnut-backed chickadee (*P. rufescens*) lives on mountains from Alaska to Montana and California. Others are found in Mexico. All are closely allied with the old world titmice, but have no crest. (*See* Titmouse.)

(G. F. Ss.)

CHICKAMAUGA. The battle of Chickamauga was fought (Sept. 19–20, 1863) in northern Georgia between the Federal army of the Cumberland under Rosecrans and *Bragg's* Confederate army. It was the one great Confederate victory in the West, rendered indecisive by subsequent events. *Bragg*, afraid of being surrounded in Chattanooga, evacuated the town, which Rosecrans occupied (Sept. 9), and withdrew to Lafayette, where he awaited reinforcements from Virginia under *Longstreet* before fighting a pitched battle. Rosecrans, when *Bragg* was found not to be retreating on Rome, hastily concentrated his three corps (Sept. 17), his left (Crittenden) on West Chickamauga creek at Lee and Gordon's mills, 12 m. S. of Chattanooga, and his right (McCook) at Stevens' gap in Lookout mountain. *Hood* with three brigades joined *Bragg* (Sept. 18), who that day had begun to move down the east bank of the creek to outflank Crittenden at the mills. His right column crossed 4 m. below, and the movement was to be taken up by the other columns in succession from right to left. *Bragg* expected to envelop Crittenden and drive Rosecrans back upon Lookout mountain, cutting him off from Chattanooga. Only two Confederate columns crossed that day; three more divisions followed early next morning. But during the night Rosecrans, who had been shifting his army all day to the left, moved Thomas's corps from the centre to the extreme left, to secure his line of retreat to Chattanooga. Thomas's night march defeated *Bragg's* plan. He was now forced to deliver battle north of the mills, to prevent his own right from being turned. Thick woods concealed the movements of both armies, and the fighting consisted of a series of independent engagements, in which each side alternately outflanked and was outflanked by the other. The battle began (Sept. 19) with Thomas sending a division on a reconnaissance towards the creek. It encountered dismounted cavalry. Both sides hurried up reinforcements and the fighting spread southward, until the whole of Rosecrans' and the greater part of *Bragg's* forces had been drawn in. The general result was favourable to Rosecrans. He had strengthened his hold on the roads in his rear, but he had put in all his forces, except three brigades of Granger's reserve corps, which were holding Rossville gap, whereas *Bragg* had still three divisions in hand and during the night was joined by three fresh brigades.

For the morrow's battle *Bragg* reorganized his army in wings, the right under *Polk*, the left under *Longstreet*, who arrived at 11 P.M., and decided to persevere with his progressive order of attack. *Polk* was ordered to advance at sunrise (Sept. 20), but the battle only began some hours later. Thomas had strengthened
